Besides these privileges, now universally considered as a part of the king's prerogative, the barons enjoyed in most of the European countries, certain benefits resulting from their territorial superiority. These were what are denominated the feudal casualties or incidents, of which we shall here give a short, though, we trust, a distinct account. They may all, without much difficulty, be traced to the nature of the feudal tenure, or the condition of military service on which the vassals received and held the portions of land which the baron assigned them. When the vassal was incapable by nonage, or otherwise, of fulfilling the condition alluded to, the fief reverted to the original possessor, and remained with him till the period of minority expired, or the cause of inability was removed. During the period of nonage, the minor was educated at the expense of the baron, and usually attended him both in the field and in the great hall of his castle. Hence arose the incident of *wardship*, designed in its first institution for the reciprocal benefit of the vassal and his liege lord; but in the end, proving to be one of the most distressful of all the feudal grievances. Nearly connected with this incident, and indeed arising from it, is that of *relief*. This was a certain sum of money, or a certain quantity of arms and habiliments of war, paid to the baron by the vassal when the term of wardship expired, and he entered on the possession of his fief. It may be regarded as an acknowledgment on the part of the ward, for the protection of his property, and the charge of his education. The feudal subject was commonly not backward to attend his lord in the field; his attendance, however, was sometimes dispensed with; and in lieu of actual service, the baron was content to accept of what was called a *scutage*. This constitutes the third of the casualties incident to the feudal tenure. But the property originally derived from the territorial superior, was not to be disposed of to another, or put into the hands of his enemies, without his consent. It might be transferred either by sale, in which case, the vassal purchased the consent of the baron by paying a *fine of alienation*, or by the marriage of female heirs, in which case the feudatory was subjected to the incident of marriage. With regard to this last incident, however, it must be observed, that though what we have now stated may justly be considered as its original character or condition, yet the territorial superior gradually acquired the *maritagium*, or right of giving his female wards in marriage to any person whatever, and in all circumstances; or of exacting a large sum if they refused to accept of his choice. In the exercise of this right, male heirs were at length included. When the bond between the vassal and his lord was dissolved, either by natural or civil means, the property reverted to the original

possessor by *escheat*. The last of the feudal casualties was the *aid*. This was at first a benevolence or gratuitous contribution on the part of the vassal, when the treasury of the baron was exhausted, when he was anxious to increase the splendour of his court or of his entertainments, to form alliances, or to recover his freedom when taken prisoner by his enemies. Aids, however, came soon to be demanded; and the feudal subject held himself bound to grant them at least on three remarkable occasions. 1. When the eldest son of the baron was to be knighted. 2. When his eldest daughter was about to be given in marriage: And, 3. When his ransom was to be paid. Occasionally, however, the tyranny of the baron exacted aids on other occasions; as to pay the debts which he had contracted, or reliefs, or scutages to his superior lord.

Having considered the barons as masters, let us next view them in the character of servants. They formed the great council of the monarch. They were summoned by him whenever the affairs of the kingdom demanded particular attention, or whenever he wished to accomplish any object by means of their assistance. As vassals of the crown, they were bound to obey the royal mandate. On the same account, they were liable to all the feudal incidents: and to these severe regulations, they submitted for many centuries, though often with great reluctance, and not without some attempts to limit the power by which they were enforced. But the connection between the king and his barons was by no means so intimate as that which subsisted between the feudal lords and their immediate dependants. For a great part of the year, and occasionally for many successive years, they lived at a distance from the seat of royal authority, while the number and attachment of their followers, as well as their military character, enabled them, either to disobey with impunity, or, if the sceptre happened to fall into weak hands, boldly to assert their independence. This immoderate power of the nobles was not acquired at once. It was the result of favourable circumstances in different reigns, and of various consecutive attempts to resist the encroachments of the prerogative. Fiefs being rendered hereditary, the property in land came, by additional grants, marriages, and otherwise, into the possession of a few great families. The consequence of this was, that the chiefs of these families lived with a splendour, and appeared with a number of retainers, scarcely inferior to those of the king. In the reign of William of Normandy, the powerful Earl of Warenne held lands in twelve different counties of England; and in Scotland, the retinue of the sixth Earl of Douglas usually consisted of two thousand horse. The next step towards the independence of the barons was that of obtaining for themselves and their families, the chief offices of trust and authority under the crown. Besides the great council, which met occasionally, and in which every territorial superior possessing land to a certain amount had the right of being present, the higher nobility formed what was called the "*Aula Regis*," or "*Cour du Roy*," a regular assembly to which the direction of affairs, both civil and military, was exclusively committed, and before which all questions of importance were tried and decided. According to Madox, (*Hist. of the Exchequer*;) the *Aula Regis* was composed of seven officers. 1. The chief justiciar, or lord justice general. 2. The constable, or principal groom. 3. The marshal, or principal smith or farrier. 4. The seneschall, or lord high steward of the kingdom, originally

also deputer, or steward of the household. 5. The chamberlain. 6. The chancellor. 7. The treasurer; originally the deputy of the high steward, and in later times that of the chamberlain. There is no doubt that these officers were at first appointed by the king, and were removeable at pleasure. In a short time, however, the places which they held, and the honours connected with them, were attached, not to the individual, but to the *liefe*. They descended, in conjunction with the property in land, to the heirs of the existing possessors, and like that property, which was at length fixed by entail, were considered as unalienable. The effect of the whole was, that "a person whose undutiful behaviour rendered him odious to his prince, or whose incapacity exposed him to the contempt of the people, often held a place of power and trust equally important to both." Robertson's *Hist. of Scotland*, vol. i. p. 26.

In no kingdom of Europe did the power of the feudal aristocracy rise to a greater height than in Scotland. Besides the usual circumstances of residence among their vassals, settling their disputes, conducting them to the field, and protecting them from injury, the Scottish nobles availed themselves of a tendency which they perceived among their followers to unite more closely under the dominion of their "liege lords." The vassal, proud of the service, and glorying in the magnificence of his chief, considered himself, and wished to be considered by others, as of the same family with him, while the baron, encouraging the fiction, and at length perhaps, persuaded of its truth, willingly acknowledged his kindredship with those who obeyed him, and saw, with pleasure, that the attachment of his dependants was strengthened by an additional tie. The whole nation was divided into clans. In each of these every individual bore the name of his feudal superior, regarded himself as a branch of his family, and was eager to support his pretensions. When engaged in disputes with the king, therefore, the nobles, followed by a multitude of bold and martial retainers, devoted to their interest, were not often inclined to yield. Retiring to their castles, frequently strong by nature, and situated in regions almost inaccessible, they violated, with impunity, the laws enacted by the Scottish parliament, afforded protection to criminals, refused to deliver them up, and set the authority of the crown at defiance. Even so late as the time of Mary, nearly one fourth part of the kingdom was summoned to attend her chief justice in arms, before a few robbers on the border could be tried for their crimes. (Keith, *Hist. of Scotland*, p. 198.) Nor was this all. In order still farther to establish their independence, the Scottish nobles entered into leagues of mutual defence and support. It is not to be denied, however, that these were originally formed, rather with a view to repel the inroads of hostile clans, than to limit the authority of the monarch. But it is equally certain, that whenever a dispute arose between any of the united families and the king, the whole association would oppose the royal pretensions, and, according to their numbers and abilities, would do so with success. In the reign of James II. the most powerful of the Scottish barons was William Earl of Douglas. But though at the head of vassals more numerous and warlike than any chieftain of his country had ever led to the field, this was not the only source of his power. He was united in firm alliance with the Earls of Crawford, Ross, and Murray, and with the whole name of the Hamiltons. These rendered him not so much the

subject of the king as his equal. And had not James, by a deed of violence, deprived him of life, and thus dissolved the association, it might have shaken the foundations of the throne, and transferred the crown from the house of Stuart to the family of Douglas.

The history of the feudal establishment in general, is replete with struggles between the nobles and the monarch. In reigns, when great vigour and activity were displayed by the king, there is reason to believe that he was often the aggressor; and that by his unusual exactions, he roused the barons, and in some degree forced them to limit his encroachments, or to resist his claims. One of the most powerful combinations of the English nobility, with a view to lighten the burden of subjection, by ascertaining their privileges, was formed in the reign of William the Conqueror; a ruler distinguished by the severity of his government. It was the tyranny of this monarch and of his immediate successor, that urged the barons to demand a charter of their liberties from Henry I. who, in the beginning of his reign, was placed in circumstances that rendered it necessary for him to court the affections of his people. Other charters of a similar nature were granted by kings, whose actions are usually considered as the most splendid achievement recorded in English history. On the contrary, it is not to be disputed, that when the sovereign was irresolute and capricious, the barons may have taken advantage of his weakness, and brought forward claims which, had they been placed in different circumstances, they would have judged it fit to suppress. Of this assertion, the reign of John affords a conspicuous and memorable proof. Destitute of vigour, skill, or perseverance, this wretched prince was first deserted by his nobles, and then constrained to retire before them. In proportion to his imbecility and the calamitous state of his affairs, they assumed a higher tone, multiplied their demands, and refused to make concessions, till, on the plain of Runnymede, they extorted from him the great charter of their liberties, which every Englishman now regards as the most valuable portion of his birth-right. This event has been celebrated by Professor Richardson, in lines worthy of its magnitude and importance:

—Hail, Runny-mede!

Illustrious field! like Marathon renowned,
Or Salamis, where freedom on the hosts
Of Persia, from her radiant sword, shook fear
And dire discomfiture! Even now I tread
Where Albion's ancient BARONS won the pledge
Of independence:—
O gallant chiefs! whether ye ride the winds,
Bound on some high commission to confound
The pride of guilty kings; or, to alarm
Their coward spirits, through the realms of night
Hurl the tremendous comet, or in bowers
Of blooming paradise enjoy repose;
I ween the memory of your patriot zeal
Exalts your glory, and sublimes your joys.

RICHARDSON'S Poem. *Runny-mede*.

The division of the barons into the *majores* and *minores*, the greater and lesser barons, must not be passed over without particular notice; as from this division the House of Commons unquestionably took its rise. According to the feudal constitution, the immediate vassal of the crown, or those who held of the sovereign *in capite*, were indiscriminately admitted into the national council. These were for the most part, men of great

estates and extensive influence. To such opulent individuals, attendance in parliament could not be burdensome. In the progress of society, however, and by the operation of circumstances, which cannot be specified here, the property of the barons was gradually dismembered, or separated into smaller portions; the number of possessors holding the same rank was very greatly increased; alienation of land became frequent; and many families, once opulent and powerful, were at length reduced to poverty and dependence. In consequence of these changes, the small barons were often inclined to withdraw themselves from an expensive attendance in parliament, and to relinquish their privilege of sitting and voting in the national council. Accordingly, their attendance was, at first, occasionally dispensed with: they were no longer individually called to give their advice and assistance. In the great charter it is distinctly intimated, that the archbishops, bishops, earls, and greater barons, (*majores barones*,) shall be personally summoned to attend the meeting of parliament "at a certain place, with forty days notice;" and that the rest of the king's tenants *in capite*, shall receive a general citation from the sheriffs of their respective counties. The next step probably was, that the small barons in particular districts, should succeed and relieve one another by turns, as often as the sovereign required their presence, (Blackstone, *Comment.* vol. i. p. 174. note). And last of all, it was found more convenient that some persons best qualified for the duty of parliament, and most willing to accept of the commission, should be chosen by general consent, and supported at the common expense, in order to represent their constituents in the chief assembly of the nation. Such is probably the way in which the knights of the shire were introduced into parliament; though, from the want of records, occasioned by the civil wars, no distinct and certain account of that remarkable event can be given. There is no doubt, however, that it took place at least in the reign of King Henry III. or about the year 1266. See PARLIAMENT.

The separation of the parliament into two houses was not exactly contemporaneous with the representation of counties by the knights of the shire. These being originally of the same rank with the greater barons, continued for some time to sit and vote in what was afterwards called the House of Peers. The same was at first the case with the representatives of boroughs, though of inferior rank. But the number of burgesses that were sent to parliament having, in a short time, been greatly augmented, they found it convenient or necessary to meet in a separate place: And the knights of the shire, being the representatives of counties as they were of boroughs, united with them, and formed themselves into a distinct assembly, called the House of Commons. On this important union, the late Professor Millar, to whom we are indebted for some of the preceding observations, makes the following remarks. "The coalition of these two orders of deputies," says this eminent writer, "may perhaps be regarded as the great cause of the authority acquired by the English House of Commons. The members of that house were, by this measure, exalted to higher consideration and respect, from the increase of their numbers, as well as from the augmentation of their property. They now represented the mercantile people and the landed gentry, who, ex-

clusive of those who remained in a state of servitude, composed the great body of the people, and who possessed a great proportion of the national wealth. Of these two classes, the landed gentry for a long time enjoyed the first rank; and the deputies of boroughs were therefore frequently chosen from among the neighbouring gentlemen, (once the lesser barons,) who, by reason of their independence, were more capable than their own burgesses of protecting their constituents. By joining together and confounding these different orders of representatives, the importance of either was in some degree communicated to both: at the same time that the people, under so many leaders, became attentive to their common privileges, and were taught to unite in defending them. Had all the constituents appeared in the national council, they would have been a disorderly multitude, without aim or direction: by choosing deputies to manage their parliamentary interest, they became an army reduced into regular subordination, and conducted by intelligent officers." *Historical View of the English Government*, vol. ii. p. 224.

The right or privilege which the barons enjoyed, of sitting and voting in the great national council, may be considered in reference to three distinct periods of English history. The first extends from the Norman conquest to the last years in the reign of King John: The second reaches from that period to the 11th of Richard II.: And the third extends from the 11th of King Richard II. to the present time. During the first of these periods, the barons held their places in the great council of the nation, or rather were obliged to attend the meetings of that council, as possessors of land belonging to the king. They were, therefore, denominated barons *by tenure*. In the second period the king assumed the privilege of calling individuals into parliament *by writ*, though these individuals were not the feudal subjects of the crown. This was unquestionably a great innovation: yet it was the opinion of Lord Coke, and is now, indeed, understood to be the law, that any person, summoned by writ to attend the meetings of parliament, who shall have once taken his seat in the upper house, becomes in all respects a baron, or procures by that circumstance a barony for himself and his heirs in full and perpetual right. In the beginning of the last period, the practice of creating peers by letters patent was introduced. For, in the 11th of Richard II., John de Beauchamp, seneschal or steward of the king's household, was declared, by patent, Lord Beauchamp of Kidderminster, in tail male.* It is true, the example of Richard was not immediately followed: yet the practice begun by that monarch became ultimately general, and peerages are now created at the pleasure of the crown, without regard either to estate or tenure.

It remains that we conclude this article by stating, that the specific rank or place of a baron, as distinguished from the other orders of nobility, is known most certainly by his coronet and robes, and likewise by the style in which he is addressed. A baron's coronet is a rim of gold adorned with six pearls or balls: his parliamentary robe is of scarlet, lined with white satin, having two guards of white fur, and two rows of gold spots upon the shoulder. His cap is the same with that of the viscount. He is styled Right Honourable, and in public documents, the Most Noble Lord. By the king

* "I remember," says *Selden*, "one instance of a spiritual baron thus created." *Titles of Honour*, part ii. p. 774.

or queen he is addressed, Right Trusty and Well-beloved. He may appoint three chaplains. See Selden's *Titles of Honour*, Part II. ch. v.; and *Additions*, p. 998, or No. 190 and 196. Blackstone's *Comment. Book I. ch. 12.* Millar's *Historical View of the English Government*, vol. ii. Stuart's *View of Society in Europe*, p. 76. (h)*

* The word *Baron* is connected with that large family of words, which in the different ancient as well as modern languages of Europe, are expressive of human strength and power. In the Greek, ἦρως, a hero, ἥρα, Juno, the lady or mistress; in Latin, *Vir*, a man, whence *Virtus*, strength, manhood, power, courage, and *Herus*, *Hera*, master, mistress, whence the German *Herr*, and its synonyma and derivatives in the northern languages. Some readers will not, perhaps, at once perceive the affinity between *Vir*, and ἦρως and *Herus*, because the letter *v*, or some other labial consonant is not found in the latter, but the same thing happens in several other Greek and Latin words, the affinity of which to each other cannot be doubted; such as *Vir*, ἦρ, Æol. ἔρ; *Vesper*, ἑσπερος; *Vesta*, ἑστία; *Vide*, ἴδε; &c.

To this class of words, which extends its ramifications even into the Celtic and Oriental languages, (see *Johnson's Dictionary*, note to the word *BARON*;) is, we believe, to be traced the derivation of the word *Baro*, which is to be found in the works of some Latin writers, even of the Augustan age, to designate a strong valiant man. See *Hirtius*, de *Bell. Alex.* l. 1. c. 53. Cicero also makes use of it in a sense which implies power or superiority. *Apud Patronem et reliquos BARONES te in maximâ gratiâ posui.* Epist. ad. Attic. l. v. Ep. 11.

From the Latin, this word naturally passed into the newly formed European idioms, as well as into the Teutonic dialects, and in the latter, perhaps, was first used as a title of nobility or distinction. At the same time, it obtained in various countries various meanings, all, however, expressive of manhood, courage, strength, and superiority. In the Portuguese language it still means a great man or hero. Thus Camoens sung,

“As armas e os Barões assinalados
Que da occidental praia Lusitana
Por mares nunca d'antes navegados
Passaram—” LUSIAD. Cant. 1.

In another, but still analogous sense, the same word is used in the Spanish language to designate the male sex; *un hijo varón*, a son; and in various countries the same word formerly signified a man, as contradistinguished from a woman, and it came to be afterwards employed in the more restricted sense of a husband. A woman said *my baron*, as the women in Germany at this day say *mein mann*, my man, instead of my husband. This mode of expression was long in use in England, and is still employed in the technical language of the law. There is no doubt that it obtained in the same manner in France; for M. de Gebelin informs us, that it is still the custom among the Walloon women to say *mon baron*, and that, perhaps, it is the same in Champagne. *Monde Primitif.—Dicit. Etymol. de la Langue Franç.* p. 131.

The word *Baron*, therefore, according to its various origins and significations in the languages of Europe, may be said to mean, when used in a favourable sense, a man, a male, a husband, a great man, a hero, a lord.

BARONET, a gentleman having the title of *Sir*, in virtue of his patent, and taking place of all knights, with two exceptions,—knights bannerets, created by the sovereign in person, in the field, and under the royal banner,—and the knights of St George, or of the Garter. This title is the lowest honour which is hereditary, and is usually descendible to the issue male.

The order of knights baronets was instituted by James I. of England, in the year 1611, at the suggestion of Cecil Earl of Salisbury, (*Hume*, viii. 283.) who recommended its establishment to the king as an expedient by which money might be raised. The money was to be employed in reducing and civilizing the province of Ulster, the inhabitants of which were at that time in arms against the English government. The form of creation is given by Selden, *Titles of Honour*, part ii. ch. v. § 46. In the preamble, the king states, that he was desirous “*nova merita novis dignitatum insignibus, rependere;*” and therefore, he adds, “*ex certa scientia, et mero motu nostris, ordinavimus, creavimus, constituimus, et creavimus, quendam statum, gradum, dignitatem, nomen et titulum BARONETTI, intra hoc regnum nostrum.*”

But it has been not unfrequently observed by etymologists, that the same word is often used not only in different languages, but in the same idiom, in senses directly opposite. Thus the word *down*, in English, in general implies inferiority in point of local situation, but sometimes also means rising or elevation, as in *The Downs*, which are hillocks on both sides of the channel, in French *les Dunes*, and in Dutch *de Duynen*, whence *Duynkerken*, *Dunkirk*, the church of the *Dowens* or *hillocks*. In the same manner, the word *Baron* has been, and is still used with the most opposite significations. Among the ancient Romans, it was employed to designate a fool or blockhead, *Eheu! BARO*, alas! fool that you are. *Pers. Sat.* 5. See also *Cic. de Fin.* 2. 23. *Epist. Familiar.* l. 9. *Ep. ult.* and *De Divinat.* lib. 2. *sub. fin.* And in the modern Italian, the word *Barone* means a knave or scoundrel.

There is a moral branch in the Etymological science, which does not seem to have been sufficiently attended to. Many curious traits of human nature may be discovered by tracing the filiation of certain words, and the train of ideas that have transferred them from one signification to another far distant from their original meaning. Thus from *captivus*, a prisoner, a captive, a word which, in its original sense, was calculated to excite the finer feelings of compassion and kindness, have issued the Italian *cattivo*, bad, wicked, and the English word *caitiff*, which Johnson explains by a mean villain, a despicable knave. This, at first, may excite astonishment, but when it is recollected, that in former times prisoners of war were made slaves of, and that to the idea of a slave, that of meanness and contempt is generally affixed, the wonder ceases, and the operation of the human mind in annexing to the same word such opposite meanings, becomes manifest. But other ideas will occur, when we enquire how the meaning of the words *virtue* and *bravery* have been so far corrupted, that in Italy nothing is more frequent than to hear of the *virtue* (*virtù*), and of the *bravery* (*bravura*) of an eunuch. And the degrading sense in which the English use the word *wretch*, and the French the words *malheureux* and *miserable*, will induce solemn and depressing reflections, on the levity, at least, not to say on the injustice and cruelty of mankind. DE POURCEAU.

Anglia, perpetuis temporibus, duraturum." The patent was originally granted to none but such as were of good birth, at least descended of a grandfather, by the father's side, that bare arms, and in possession of a yearly income amounting to 1000*l.*; and the number of those who could receive it was limited at two hundred. By the terms of the patent, every individual admitted to the honour, was either to raise 50 foot-soldiers, and maintain them in Ulster, at his own expense, during a period of three years, or, what was rather wished, to pay into the exchequer the sum of 1000*l.*, which was supposed to be nearly an equivalent. Accordingly, commissioners were appointed to sit at Whitehall, with a view to receive those who might apply; and one hundred gentlemen, advancing each a thousand pounds, had the title of baronet conferred upon them. Of these, Sir Nicholas Bacon, of Redgrave, in Suffolk, was the first: a circumstance, on account of which, his successor is still designated *Primus Baronettorum Anglic.* The number of baronets have since been augmented greatly beyond the limit at first intended.

All the baronets of England have, superadded to their family insignia, the arms of the ancient kings of Ulster, viz. A hand, *gules* or a bloody hand, in a field *argent*. These they may bear, either in a *canton* or in an *escutcheon* of pretence. Both they, and their eldest sons on coming of age, have the privilege of demanding knight-hood. The word *Baronet* is placed at the end of their surnames, and their wives are styled *Lady* or *Dame*. The rank or place of baronets, with regard particularly to the younger sons of barons and viscounts, was for some time matter of keen dispute, but was at length settled in a laborious document published by authority of the king, (James I.) which those who have a taste for such papers and composition, will find in Selden, *Tit. of Hon.* ch. xi. § 3d. In this document it is announced, that his majesty, who best knew his own royal meaning when he founded the order, "hath finally sentenced, adjudged, and established, that the younger sons of his counts and barons shall take place and precedence before all baronets." Among themselves, the baronet's rank according to the date of their patents.

The baronets of Scotland are otherwise called baronets of Nova Scotia. This institution was likewise designed by James I. and was regarded by him as a method at once honourable and easy of cultivating the province of Nova Scotia in North America; a part of the western continent, which had already been discovered and occupied by the English. James, however, was prevented by circumstances which we cannot mention in this place, from executing his purpose; and the order was not established till the year 1625, in the reign of his son Charles I. Sir Robert Gordon of Gordonstone, a cadet of the Sutherland family, was the first baronet of Nova Scotia. A certain portion of land in Acadia, or New Scotland, was granted to each of those on whom the dignity was conferred, and to their heirs in perpetual succession: this land they were to hold of Sir William Alexander, afterwards created Earl of Stirling, and at that time his majesty's lieutenant in Nova Scotia. But, from the ignorance which then prevailed with respect to the geography of North America, it may easily be conceived that the land was not portioned out with great accuracy; and that these titled adventurers would not only be frequently altogether unacquainted with the exact bounds prescribed for them, but that their characters would sometimes interfere with each other. In

the letters patent it was declared, that the baronets of Nova Scotia, and their heirs and successors, should have precedency of all knights called *Jurati*, of all the lairds or inferior barons of Scotland, and of every other gentleman not belonging to the higher orders of nobility, excepting the king's lieutenant above mentioned, and his heirs male, together with their wives and children. They were to be addressed *Sir*, and to have the word *Baronet*, in all writings and documents adjoining to their names. Their wives, like those of the English baronets, are styled *Lady* or *Dame*. The knights of this order have likewise the privilege, granted to them under the sign manuel, A. D. 1629, of wearing round their necks "an orange-tawney coloured silk ribbon," from which hangs a medal with an imperial crown above the *escutcheon* of the Scottish arms, inscribed with this motto, *Pax mentis honestæ gloria*. In addition to their family arms, they bear, either in a *canton* or in an *escutcheon*, the insignia of Nova Scotia; i. e. *argent* a cross of St. Andrew, *azure* charged with an *escutcheon* of the royal arms of Scotland; having, for supporters on the right, the royal unicorn, and on the left, a savage or wild man, *propter*. The crest is a branch of laurel, and a thistle issuing from two hands conjoined: the motto, *Munit hæc, et altera vincit*.

This order has experienced a considerable variety of fortunes. It was confirmed and established by a convention of estates, A. D. 1630, and by an act of the Scottish parliament, A. D. 1633. During the usurpation of Cromwell, the title and dignity were almost annihilated. They were little known during the reign of Charles II. After that period, some attempts were made to restore them, particularly in the years 1721 to 1734; but without effect. At length, however, in the reign of our present king, and in the year 1775, such measures were taken as have raised the knights baronets of Nova Scotia to their original dignity. (*h*)

BARRA, a kingdom of Africa, situated on the north bank of the Gambia, at the mouth of that river, and extending about eighteen leagues along the coast. As this kingdom is more worthy of notice than any of those upon the river Gambia, we shall present our readers with a very interesting account of it from Durand's *Voyage to Senegal*.

The kingdom of Barra is almost entirely peopled by strangers, as the natives of the country are there only few in number. The greatest population is that of the Mandingoes or Mandings, so called from the name of their native country Mandin or Mandingue, which is situated about four hundred leagues to the east, and is prodigiously peopled, as is evident from the vast number of slaves which it furnishes every year, as well as from the colonies, which frequently proceed from it, to extend their active industry to other quarters. It was thus that there arrived in the kingdom of Barra those who are considered as natives, and who have possessed themselves of the supreme power, and the whole of the commerce; the king and his great men being Mandingoes. They are the only well informed persons in the state for they know almost every thing, and can read and write. They have public schools, in which the Marabouts, who are the masters, teach the children the Arabic tongue; their lessons are written on small pieces of white wood: but they give the preference to the paper which we have introduced among them. When they know the alcoran, they obtain the title of doctors.

It is remarkable, that the Mandingoes, who have all

come from a republican state, have formed nothing but monarchies wherever they have established themselves; but they have not invested their kings with unlimited authority. On all important occasions, these princes are obliged to convoke a meeting of the wisest old men, by whose advice they act, and without which they can neither declare war nor make peace.

In all the large towns, the people have a chief magistrate, who bears the name of alcaide, and whose place is hereditary: his duty is to preserve order, to receive the tribute imposed upon travellers, and to preside at the sittings of the tribunal of justice. The jurisdiction is composed of old men who are free; and their meeting is called a palaver: it holds its sittings in the open air, and with much solemnity. The affairs which are brought for discussion are investigated with much candour; the witnesses are publicly heard; and the decisions generally excite the approbation of both parties.

They have no written laws, but decide on the cases according to their ancient customs; nevertheless, they sometimes have recourse to the civil institutes of Mahomet; and when the Koran does not appear to them sufficiently perspicuous, they consult a commentary entitled *Al Scharra*, which contains a complete exposition of the civil and criminal laws of Islamism. They have amongst them people who exercise the profession of counsellors, or interpreters of the laws, and who are allowed to plead either for the accuser or the accused, as at European tribunals: these negro-lawyers are Mahometans, and have, or pretend to have, studied, with particular attention, the institutions of the prophet. In the art of chicanery they equal the most acute pleaders of civilized countries.

These people follow the laws of Mahomet, of which they are rigid observers: most of them neither drink wine nor spirits; and all fast with the utmost rigour during the Maradan or Lent. They breed no hogs, because their laws forbid the eating of their flesh; though they might sell them to great advantage. They are very affectionate amongst themselves, and always assist each other. It is not understood that they make slaves, as this punishment is only decreed by the king and chiefly against the great people who are guilty of crimes. In other respects they are more polished than the rest of the negroes; are of a mild character, sensible, and benevolent: all which qualities may be attributed to their love for commerce, and to the extensive travels in which they are continually engaged. The ease with which they cultivate their lands proves their industry: they are covered with palm, banyan, fig, and other useful trees. The people have but few horses, though the country is well adapted to breeding them; but they have a number of asses, which they use for travelling, and their territory abounds with wild buffaloes.

The Mandingoes are particularly industrious in making salt, which they do in a peculiar manner. They put river water in the halves of calabashes, or in shallow earthen pots, and expose it to the sun, the heat of which produces crystals of salt, the same as in ordinary pits: for the water is always much impregnated with the saline principle, as the sea mixes with it a considerable way up the river. In a short time after the calabashes have been exposed, a cream of fine white salt is formed on the surface, and this is taken off three or four times; after which the vessels are filled again. They have also very abundant salt-pits at Joal and Faquiou, and their produce forms an important branch of trade; they load

their canoes with it; and ascending the river as far as Barraconda, they exchange it for maize, cotton stuffs, ivory, gold dust, &c.

The great number of canoes and men employed in this commerce gives great influence and respect to the king of Barra. Indeed he is the most powerful and terrible of all the kings of the Gambia; he has imposed considerable duties on the ships of all nations, each of which, whatever may be its size, is obliged to pay on entering the river, a duty equal to about five hundred livres, or nearly 21*l.* sterling. The governor of Gillifric is charged with the receipt of these duties, and he is always attended by a number of persons who are very importunate: they are incessantly asking for whatever pleases their fancy, and pursue their demands with such ardour and perseverance, that to get rid of them the navigators are almost always obliged to satisfy their desires.

The Mandingoes are above the middle size, are well made, robust, and capable of bearing great fatigue. The women are stout, active, and pretty. The clothes of both sexes are of cotten, which they manufacture themselves. The men wear drawers, which hang half way down the thigh, and an open tunic, similar to our surplice. They have sandals on their feet, and cotton caps on their heads. The women's dress consists of two pieces of linen six feet long and about three wide; the one is plaited round the loins, and falls down to the ankle, forming a kind of petticoat; while the other negligently covers their bosom and shoulders,

Their habitations, like those of all the other negroes, are small and inconvenient huts. A mud wall about four feet high, over which is a conical opening made of bamboos and straw, serves for the residence of the rich man, as well as of the humblest slave. The furniture is equally uncouth: their beds are made of a bundle of reeds placed on pickets two feet high, and covered with a mat or an ox's skin; a jar for water, a few earthen vessels for boiling their meat, with some wooden bowls, calabashes, and one or two stools, form the whole of their household goods.

All the Mandingoes in a free state have several women; but they cannot marry two sisters. These women have each a hut; while all the hovels belonging to one master are surrounded by a lattice-work of bamboo, made with much art: an assemblage of this kind is called *Sirk*, or *Sourk*. Several of these enclosures, separated by narrow paths, compose a town; but the huts are placed with much irregularity, and according to the caprice of the person to whom they belong. The only point to which they attend is to have the door in a south-westerly direction, that it may admit the sea breezes.

In each town a spot is set apart for the assemblies of the old men; it is enclosed by interlaced reeds, and generally covered by trees which protect it from the sun. Here they discuss public affairs, and try causes; the idle and profligate also resort hither to smoke their pipes and hear the news.

In several parts they have missourates or mosques, where they meet to say the prayers prescribed by the Koran.

The population of the free Mandingoes forms, at the utmost, about one-fourth of the inhabitants of the country which they occupy. The remaining three-fourths are born in slavery, and have no hope of escaping from it: they are employed in all servile labours; but the free Mandingo has no right to take the life of his slave,

nor to sell him to a foreigner, unless he has been publicly tried, and decreed to deserve such a punishment. The prisoners of war, those imprisoned for crimes or debt, and those who are taken from the centre of Africa and brought to the coast for sale, have no right to appeal, as their masters may treat and dispose of them according to their fancy.

Another part of the population of the kingdom of Barra, is composed of the descendants of the Portuguese families who remain in the country, and of whom we have already spoken. Such persons, or rather those who take the title of Portuguese (for all the Mulattos, and even men who are almost black, call themselves Portuguese, and to doubt their origin is an affront they do not pardon,) profess the catholic religion, and have churches and priests in different parts. They are recognised by their costume; they wear a great chaplet suspended from the neck, a very long sword by their side, a shirt, a cloak, a hat, and a poignard.

Some of these people devote themselves to commerce and agriculture, and are generally adroit, brave, and enterprising. They acquire property, live happily, and are much esteemed; but by far the greatest part live in the most complete state of idleness, and in consequence of being poor, addict themselves to thieving; they also pass their time in the most disgusting state of libertinism, and are equally despised by the Mahometans and the Christians.

The industrious part of these people proceed to the top of the river in the canoes or boats of the country, and generally perform such voyages on account of the French, who entrust them with merchandise, and pay them liberally. They have sometimes been attacked in their voyage, but they always proved that they knew how to defend their liberty and property. They have also learnt from their ancestors never to pardon wrongs nor injuries; and if this be not a precept of their religion, it is a command of their fathers which necessity justifies. M. Durand is of opinion that it is possible to employ, with great advantage, these men, so inured to the climate, to travel over and make discoveries in the interior of Africa.

The Portuguese build their habitations according to the plan of their ancestors, by which they are more solid and commodious than those of the Negroes: they raise them two or three feet above the soil, to secure them from the damp, and give them a considerable length so as to divide each house into several chambers. The windows they make are very small, in order to keep out the excessive heat of the climate; and they never fail to build a vestibule open on all sides, in which they receive visits, take their meals, and transact their business. The walls are seven or eight feet high, and, as well as the roof, are of reeds covered on both sides with a mixture of clay and chopped straw: the whole is coated with plaister. They take care to plant latane, or other trees, before their houses, or to build them on a spot where such trees are growing, in order to enjoy the refreshing shade which they produce. The king of Barra and the greatest people of his kingdom have similar places of residence. West Long. $16^{\circ} 45'$, North Lat. $13^{\circ} 40'$. (q)

BARRA, or **BARRAY**, one of the Hebrides, or western islands of Scotland, about 6 miles long, and $2\frac{1}{2}$ broad, annexed to the county of Inverness. This island, which is low and flat on the west side, and steep and irregular on the east, produces barley and oats, and is well stored

with black cattle. Great quantities of cod and ling are caught on the east coast; and in one year no fewer than 30,000 were sent to Glasgow, and sold for about five or six pounds per hundred. The dog fish, which are occasionally caught, supply the inhabitants with oil for their lamps. Shell fish, of various kinds, are found here in great abundance. Cockles are particularly abundant, and in some seasons of scarcity have been almost the chief food of the inhabitants. Kelp is manufactured in Barra in considerable quantities. West Long. $7^{\circ} 30'$, North Lat. $57^{\circ} 2''$. (j)

BARREN ISLAND, the name of one of the Asiatic islands, situated in North Lat. $12^{\circ} 15'$, and about fifteen leagues to the East of the Andaman isles. It is about six leagues in circuit; and is distinguished by a violent volcano, which throws out showers of red-hot stones, and volumes of smoke. The mountain rises from the lower part of the island, which is a little above the level of the sea, with a slope of $32^{\circ} 17'$, to the height of 1800 feet, which is the average height of the other parts of the island. See *Asiatic Researches*, vol. iv. p. 395. (w)

BARRENNESS, signifies either a total incapability of conceiving children, or of retaining the embryo till it becomes formed. Many women can conceive, but cannot retain the ovum above a few days. Sterility depends on the state of the womb and its appendages. These organs are sometimes malformed, or organically unfit for performing their functions; but in a much greater number of instances they are well formed, but have not the power of acting vigorously; in the same way as a stomach which is sound in point of structure, may be incapable of digesting properly. This incapacity may be connected with, or dependant on, a general condition of the system, such as great irritability, plethora, or debility; or it may be consequent to the operation of causes chiefly or entirely local, such as too frequent or promiscuous intercourse; or circumstances affecting the condition of the menstrual discharge, producing obstruction, or painful and sparing menstruation, or too copious or too frequent discharge, or fluor albus.

Some specific substances have, without foundation, however, been said to produce sterility, such as beans, leeks, carrot seeds, sage, &c. taken internally; or the application to the womb itself of rue, vinegar, or camphor.

There are instances where a woman is barren with one husband, and fruitful with another.

A variety of means have been employed for the removal of this reproach among women. When it depends on organic causes, these, unless the deviation be external, can seldom be remedied by an operation. But, in general, the structure appears to be correct; and then the most judicious practice is to consider what particular state either of the constitution or of the womb may have occasioned sterility, and to employ suitable remedies, especially for restoring the menstrual discharge to its proper condition. Seabathing, tonics, mineral waters, and, in some cases, laxatives, are usually had recourse to for this purpose, and generally, a restrained intercourse is advisable. When these means are neglected, nature seems, in some instances, to remove the cause, particularly when this consists in inordinate menstruation, or too great irritability of the womb. Thus women, who have been long barren, have at last born children; others, by a different mode, have

been successful. Fernelius having been consulted respecting the queen of Henry II. of France, who had been ten years barren, "*conseilla au roi de n'approcher de sa femme qu'au moment de l'eruption facile de ses regles; et ce precepte executé fut si efficace qu'il devint pere de dix enfans.*"

Sterility is, by the laws of every country, considered as a legal ground of separation. The Jews were very lax in their notions respecting divorce. The Hindoos allow of it, not merely for sterility, but also for bearing only female children. By the laws of China, barrenness is the first of seven causes justifying divorce; and it is not a little singular, that in this nation of semi-barbarians, talkativeness is another cause equally valid. By the Koran, the process is, in many cases, very short; for if a wife is not pregnant, and at the same time does not menstruate for three months after marriage, the husband may put her away as barren. By the English and Scots law, sterility is a ground for divorce *a mensa et thoro*. It may, notwithstanding all these authorities, be justly questioned, how far barrenness alone can ever be an adequate cause for dissolving marriage. Besides the great difficulty of proving that a woman is altogether incapable of conceiving and bearing children, it is no better reason for divorce than any of the other visitations of Providence, many of which render the woman helpless, useless, and even loathsome; and yet in these cases the laws of civilized society do not permit of a dissolution of the engagement, more than they would sanction the practice which prevails in some nations, of knocking the aged and infirm on the head. By the mild precepts of the Author of Christianity, no divorce can be obtained for any cause but unfaithfulness to the marriage vow. See Vigarous, *Maladies des Femmes*; and Burns's *Principles of Midwifery*, &c. (1)

BARRERIA, a genus of plants of the class Syngenesia, and order Monogynia. See **BOTANY**. (w)

BARRINGTONIA, a genus of plants of the class Monadelphia, and order Polyandria. See **BOTANY**. (w)

BARROOLOS, the name of a tribe in Southern Africa, whose country has never been visited by any European. According to the testimony of a Hottentot, with whom Mr. Truter conversed, the Barroolos are a good natured and ingenious people, who inhabit a district about ten days journey from Lectakoo, the capital town of the Booshuanas. Their towns are very numerous; and the largest of them is of such a size, that the length of it is a whole day's journey. Their houses be represented as better built, and their fields as better cultivated than those of the Booshuanas. Trees, shrubs, and rivers, decorated the surface of the country, while the soil was every where productive. They were said to be particularly skilful in carving wood and ivory; and the Hottentot had seen the furnaces by which they obtained iron from brown earth and stone, and copper from a grey earth. See Barrow's *Voyage to Cochín China*. (7)

BARROW, ISAAC, an eminent theologian and a profound mathematician, was born in London, October 1630. His father, Thomas Barrow, merchant, was brother of the bishop of St Asaph, and nearly related to several other distinguished men. He received the earliest part of his education at the Charter-house, where he was remarkable only for inattention, slovenliness, and a most quarrelsome disposition. His father, who had destined him for a learned profession, was so discouraged by these untoward appearances, that he

often wished, if Providence were ever to deprive him of any of his children, that it might be Isaac, from whom he promised himself no comfort. But having afterwards sent him to a school at Felsted in Essex, he soon perceived the dawn of his future excellence. At the age of fifteen, he was placed at Trinity College, Cambridge, where he was supported chiefly by the liberality of the learned Dr Hammond. His father's circumstances had been greatly reduced by his attachment to the cause of the unfortunate Charles I.; and young Barrow, who had imbibed the same loyal partialities, could not be prevailed upon, by any temptation of interest, to declare his adherence to the republican party. Yet, by his diligence, prudence, and candour, by the manliness of his principles, and the purity of his morals, he recommended himself to the esteem of the heads of the university, though little favour could then be expected by any who refused to subscribe the covenant. During his residence at the university, he applied with great eagerness to every branch of useful learning; but his chief attention was paid to the writings of Bacon, Galileo, Descartes, and the other reformers of philosophy. In 1649, notwithstanding the odium to which his loyalty exposed him, his indisputable merit obtained him a fellowship; and for some time after his election, being convinced that a man of his principles could have no opportunity of being useful in the church, he resolved to make physic his profession. For a few years, therefore, he applied to the study of anatomy, chemistry, and the other branches of a medical education; but after farther deliberation, he returned to the study of divinity, from which he conceived he could not withdraw, without violating the oath he had taken at his admission to a fellowship.

It is affirmed, that he was led to the study of mathematics by reading Scaliger on Eusebius. Perceiving that chronology is founded on the basis of astronomy, he began to read some works on this science; and foreseeing that his labour would be fruitless, unless he previously gained an acquaintance with the principles of geometry, he determined to make himself master of the writings of the ancient mathematicians. Not satisfied with improving his own mind by these exercises, to which he bent his attention with almost unprecedented perseverance, he prepared and published more correct editions of the works of Euclid, Archimedes, and Apollonius, than had hitherto been presented to the world. This, however, is not the whole extent of his merit. Though not of a genius so inventive as Newton, he made a near approach to some of that wonderful man's discoveries, and contributed in a very remarkable degree to enlarge the field of mathematical learning.

Barrow was recommended by Dr Duport, on his resignation of the Greek professorship, as the fittest person to succeed him; but, though his qualifications were universally acknowledged, his alleged tendency to Arminianism obstructed his advancement on this occasion. In 1654, he travelled into France, and had the happiness of administering to the wants of his father, whom he found at Paris, in the retinue of the English court. From France he proceeded to Italy, and resided for some time at Florence, where he perused many books and medals in the grand duke's library. He was deterred by the plague from visiting Rome, and, in the end of the year 1657, he sailed for Smyrna. During the voyage, he had an opportunity of signaling his courage in a fierce and obstinate engagement with a pirate. He

remained in Turkey more than a year, and at Constantinople he employed himself in reading the works of Chrysostom, formerly bishop of that see, and in studying the institutions and manners of the people. He returned home by the way of Venice, Germany, and Holland, and, soon after his arrival in England, he was ordained by Bishop Brownrigg.

At the Restoration, it was expected that he would have received some mark of the royal favour, corresponding to his deserts; but, like many others, who had sacrificed their interest in the cause of loyalty, he had the mortification of experiencing the monarch's neglect. His feelings on this occasion were expressed in the following lines:

Te magis optavit rediturum, Carole, nemo;
Et nemo sensit te rediisse minus.

Soon after this period, however, literary distinctions were rapidly bestowed on him by the best judges of his merit. In 1660, he was elected to the professorship of Greek at Cambridge. In 1662, he was appointed professor of geometry at Gresham College; and in 1663, he was chosen, by Mr Lucas's executors, to fill the mathematical chair at Cambridge. In 1664, he resigned the Gresham lecture, and was succeeded by the justly celebrated Dr Robert Hook. In 1669, determining to confine his attention to divinity, he resigned his professorship at Cambridge, in favour of Isaac Newton, then in his 27th year, whose marvellous attainments Barrow was the first to celebrate and to reward.

After his resignation, he applied with great assiduity to the composition of sermons, though he had not yet obtained any benefice in the church. About seven years, before, he had been offered a valuable living, on condition of educating the patron's son; but he chose to decline a favour, burdened with a stipulation which he thought simoniacal. In 1670 or 1671, his uncle, the Bishop of St Asaph, gave him a small sinecure in his diocese, and the Bishop of Salisbury gave him one of the prebends in his church; both of which he retained only till 1672, when, in his 42d year, he was made master of Trinity College, Cambridge. This promotion he owed entirely to the high opinion entertained of him by the king, who said, he had bestowed it on the best scholar in England; and his majesty's choice was approved by the almost universal suffrage of the learned.

From this period he was engaged chiefly in attending to the interest of his college, and in writing his theological works, particularly his elaborate treatise *On the Pope's Supremacy*. In 1676, he was vice-chancellor of the university. On the 4th of May 1677, he died suddenly of a fever, brought on, it was believed, by the fatigue of preaching the passion sermon at Guildhall Chapel, in the city of London. He was buried in Westminster Abbey. In his person Dr Barrow was below the middle size, and of a slender make, but remarkably firm and robust. His complexion was fair, his eyes grey, his hair auburn, naturally very much curled; and it was remarked, that in his countenance there was a striking resemblance to that of Marcus Brutus, as it is represented on ancient medals. He was always negligent of his dress, and immoderately addicted to the use of tobacco; but, in every other particular, his appearance and deportment tended to ingratiate him with all who saw him. His conduct was uniformly amiable and dignified, his equanimity unruffled by the storms of

the times, his moderation and candour unabated by the controversies, ecclesiastical and political, in which he engaged. His understanding, clear and active, was highly improved by the most extensive and varied reading; but his imagination, fertile and luxuriant, was not sufficiently controuled by the correctness of his judgment. He was intimately acquainted with the fathers of the church, and appears to have inherited a share of their credulity. His sermons and theological writings are contained in three volumes folio. They display a great copiousness of matter, and a still greater copiousness of words. The vigour of the expression is more remarkable than either its precision or its gracefulness; but his language, with all its faults, is often more accurate than his reasoning. His unwieldy and undisciplined eloquence frequently surprises, but seldom delights. He possessed the rare talent of being prolix, yet nervous, and diffuse, without any trace of imbecility or languor. But the discourses of Barrow, though far from being faultless models of style, are entitled to the more substantial praise of being animated throughout with the flame of piety and benevolence; so that (to use the words of his friend Dr Tillotson) "he must either be a perfectly good, or prodigiously bad man, that can read them over without being the better for them."

Though the attention of Dr Barrow was principally directed to theology in the latter part of his life, yet his mathematical writings have obtained him a high rank among the philosophers of the 17th century. His *Lectiones Geometricæ*, published in 1669, are filled with profound investigations respecting the properties of curvilinear figures; and in the method of tangents, which he has explained in that work, we clearly discover the germ of the fluxional calculus. This ingenious method, which is a great simplification of the rule given by Fermat, differs in nothing but the notation from the method of finding the subtangent by the differential calculus. The optical lectures of Dr Barrow are distinguished by the same original views which characterise his lectures on geometry. His beautiful theory of the apparent place of objects seen by refraction, or reflection, and the elegant determinations which he has given of the form of the images of rectilinear objects received from mirrors and lenses, entitle him to the highest praise. By pushing these researches a little farther, Barrow could not fail to have discovered the caustic, or Tschirnhausenian curves.

Besides his sermons, which are posthumous, the following works were published by him. *Euclidis Elementa, et Data*; *Archimedis Opera*; *Apollonii Conicorum*, lib. 4.; *Theodosii Sphærica*; *Lectiones Opticæ* 13; *Lectiones Geometricæ*; *Lectio de Sphæra*; *et Cylindro*; *Lectiones Mathematicæ*; *Opuscula Theologica, Poemata, Orationes*. (&)

BARROWS, are mounds of earth, generally of a conical form, which were raised, in ancient times, over the dead bodies of heroes, and persons of distinction. The natural desire of cherishing the remembrance of departed worth, has given rise, in all nations, to the custom of erecting monuments to perpetuate the names of those whose deeds had merited public gratitude or admiration, and to mark out to affectionate curiosity the spot consecrated by their ashes. The form, as well as the materials of these monuments, varied with the circumstances of the people who reared them, and particularly with their improvement in the arts; but the

obvious and simple mode of heaping mounds of earth over the graves of the deceased seems universally to have prevailed during that rude state of society, when the art of architecture was unknown. Accordingly, mounds of this kind are still to be found in all the quarters of the globe; and it is curious enough to trace, in these receptacles of the dead, the gradual progress of elegance and refinement, and the variations in the public taste. At first, perhaps, these barrows consisted of loose earth thrown upon the body, and gradually augmented, like the cairns in Scotland, by the casual contributions of pious passengers. The height of these barrows, being thus proportioned to the general reverence for the deceased, would be supposed to confer a corresponding distinction; the affection or the pride of individuals would lead them to claim, for their departed relatives, an honour at first bestowed by public favour; and the great and the wealthy would emulate each other in the magnificence of their family monuments. Hence, in Egypt, where magnitude was supposed to constitute grandeur, the simple cairn or barrow swelled in time to the dimensions of the stupendous pyramid. In Greece, the barrow long retained its original simplicity of form; though those of the rich and eminent were distinguished by the valuable and splendid urns which they enclosed. Homer, in describing the funeral ceremonies performed in honour of Patroclus and Hector, has given us an account of the construction of these barrows. We shall quote, from Mr Pope's translation, the description of the interment of Patroclus, which is somewhat more minute than that of Hector:—

—“Where yet the embers glow,
Wide o'er the pile the sable wine they throw;
And deep subsides the ashy heap below.
Next the white bones his sad companions place,
With tears collected, in a golden vase.
The sacred relics to the tent they bore;
The urn a veil of linen cover'd o'er.
That done, they bid the sepulchre aspire,
And east the deep foundations round the pire;
High in the midst they heap the swelling bed
Of rising earth, memorial of the dead.”

ILIAD, 23, 310.

In process of time, as the Greeks began to acquire a taste for magnificence, their barrows were decorated with the statues of animals, or with pillars bearing inscriptions in praise of the illustrious dead.

The Asiatic barrows, though less stupendous than the pyramids of Egypt, were sufficiently grand to excite the admiration of all who beheld them. One of the most famous of these was the tomb of Alyattes, king of Lydia, and father of Cræsus, which stands in the midst of several others, on the bank of the lake Gygæus, where the burial places of the Lydian princes were situated. The surrounding barrows are of various dimensions; some of them tower to such a height as to appear at a distance like hills; but they are all greatly overtopped by that of Alyattes, which, reared on a lofty basis, about three quarters of a mile in circumference, rises to the height of 200 feet. All these barrows are covered with green turf, and still retain their conical form, without the smallest sinking in of their summits.

The savage tribes of America raise the same kind of monuments in honour of their dead. Mr Jefferson, in his Notes on the State of Virginia, gives a particular account of the opening of a very large barrow in his neighbourhood; which consisted of thick strata of bones,

promiscuously strowed with alternate strata of earth. It is not ascertained on what occasion these barrows may have been made; but they differ from all others in this, that they are the general receptacles of immense numbers of dead bodies, and not the monuments of individuals. It seems probable that they were raised on the scene of memorable battles, and inclosed the bones of those who had fallen for their country. They are at least of considerable notoriety among the Indians; for Mr Jefferson informs us, that “a party of them passing about thirty years ago through that part of the country in which this large barrow is, went through the woods directly to it, without any instruction or inquiry, and, having staid about it some time, with expressions which were to be construed to be those of sorrow, they returned to the high road, from which they had deviated about six miles, purposely to pay this visit.”

Innumerable barrows are scattered through various parts of England, but particularly in the downs of Wiltshire and Dorsetshire. Many of these have been opened, and found to contain skeletons, urns, ashes, beads, and other relics. In Scotland and Wales, the barrows are in general made of loose stones, and are known by the name of *cairns*. (See *CAIRN*.) But in the links of Sandwick, one of the Orkney islands, there are a great number of round barrows, some formed entirely of earth, and others of stones covered with earth. As these barrows generally contained two tiers of coffins, it is probable that they were family vaults, and that, on the death of any one of the family, the barrow was opened, and the body interred near its kindred bones. In Ireland, too, barrows are very numerous; and are supposed by Ledwich to have been of Scythian origin. Odin, the deity and legislator of the Goths, ordained that large barrows should be erected to the memory of celebrated chiefs: these barrows were composed of stone and earth, and their construction bespeaks amazing labour, with no small degree of art. The most remarkable monument of this kind to be seen in Ireland, is that at New Grange, in the county of Meath. It is founded on a vast collection of stones, covered with gravel and earth. Its base extends over two acres of land: it rises to the height of 70 feet; and is 300 feet in circumference at the top. (For a more particular account of this mound, see *NEW GRANGE*.) Sepulchral monuments of the same description as that at New Grange, are frequent in Denmark, Sweden, Russia, Poland, and the steppes of Tartary; and hence it has been conjectured that this mound is of Danish construction.

So much for the sepulchral character of Barrows: But there is another no less interesting aspect, in which the British barrows at least are to be viewed; viz. as parts of an amazing system of vigilance and communication. “These barrows,” says Mr Stackhouse, “are like as many mirrors, placed with such optical skill and accuracy, that they conduct the visual ray from point to point, through all the windings and recesses of those circuitous dells which they are evidently intended to overlook.” We are informed by Cæsar, that the Gauls, from whom the Britons descended, conveyed intelligence with wonderful celerity through the fields and cantons, by shouting with all their might; thus the news was communicated from one to another, so that what happened at Orleans at sunrise, was known at Auvergne before nine in the evening, though the distance is 160 miles. (*De Bello Gallico*, lib. vii. cap. 3.) Mr Stackhouse conjectures, therefore, with great pro-

bability. that persons must have been regularly stationed for the express purpose of conveying tidings of any remarkable event, otherwise these dispatches must have been liable to continual interruption. To this purpose, and to a much more speedy communication, the barrows, constructed and arranged according to principles, which, after an attentive examination, he has plainly detected, are most admirably adapted. The principles of their construction and position are these: 1st, They form intermediate points of *direct* communication, either between the castles and the beacons, (the extremities of the immense chain of vigilance and defence,) or between the temples and the nearest castle. 2d, They communicate *reflectively* from one to another through all the windings of those dells which intersect the downs. 3d, One or more barrows are placed at the extremities of a long and straight valley, so as to command a longitudinal view of the same. 4th, Barrows are sometimes ranged on the sides of these long dells, so as to command a lateral view of the opposite declivities. 5th, The magnitude and position of each barrow is determined by the point to which its visual line is directed, and not, as has been supposed, by its monumental office, or the dignity of the person interred within it. 6th Groups of barrows are uniformly limited to the downs only; but eminent stations are occasionally distinguished by one or two barrows, in parts of the country to which the barrow system is not adapted, and where, of course, they can only occur in this detached manner. 7th, A barrow is never found larger than its station; that is, the point to which its visual line is assigned, requires. 8th, Where a barrow of extraordinary magnitude was necessary, no labour has been spared. 9th, Barrows are seldom found in low situations; but where a barrow is erected in a hollow or valley, it is almost always a very large one. 10th, The visual lines from the barrows on the summit of a ridge, often terminate at a distance from the foot, so as to leave room for a body of men to move along unseen: this is remedied by placing one or more barrows so as completely to command the whole range of the declivity at its base. 11th, The whole of these particular principles are concentrated into this general one, that there is not a single spot, within the barrow district, which is not exposed to at least one of these all-pervading points; and such is the perfection with which this great design is executed, that even a single individual could not proceed twenty yards in any direction without being seen, supposing the watch on these barrows to be set. The illustration of these principles is taken by Mr Stackhouse from the Dorchester Downs; and after walking considerably above a hundred miles among the barrows in the vicinity of Dorchester and Weymouth, he found it impossible to get wholly out of sight of them all, except in two or three instances, where the plough has completely levelled, or greatly depressed, the barrow assigned to that particular station. For further information on this subject, we refer our readers to Stackhouse's *Illustration of Tumuli or Ancient Barrows*; Gough's *Sepulchral Monuments of Britain*; Douglas's *Nennia Britannica*; King's *Munimenta Britannica*; *Philosophical Transactions*, No. 458.; *Archæologia*, vol. ii. and xii.; Britton's *Beauties of Wiltshire*, vol. ii.; and Clarke's *Travels in Europe, Asia, and Africa*, part i. p. 316, 428, &c. (u)

BARRY, JAMES, a celebrated historical painter, was born in the city of Cork, on the 11th October, 1741.

His father was a coasting trader between England and Ireland, and wishing to engage James, his eldest son in the same employment, compelled him, when a boy, to make several voyages. But the active and expanding genius of young Barry could not be reconciled to the drudgery and uniformity of a sailor's life. On one occasion he fairly ran away from his ship; and in his future voyages, instead of learning to handle with dexterity the ropes and sails, was generally occupied in sketching, with black chalk, the scenery of the coasts or in drawing such figures as his fancy suggested. Convinced, therefore, that he would never become a good sailor, his father resolved at length to indulge his propensity for study, and to give him all the education which his native city could afford. Never, perhaps, was more unwearied industry displayed at such a tender age. Disdaining the childish amusements of his school-fellows, he employed all his moments of leisure in his closet, either studying with avidity some favourite author, or attempting to delineate with his pencil the various expressions and attitudes of the human countenance and figure. His slender allowance of money was saved for the purpose of purchasing candles, to enable him to prosecute his studies during the night; and when his mother, alarmed for the safety of the house, deprived him of his candles in order to force him to bed, he used to lock himself up in his room, and allow no person to enter on any occasion or pretext. The same turn of mind led him to court the society of men of education, whom he in general delighted by the unaffected eagerness of his curiosity, and the manly sedateness of his manner. He perused, with the most careful attention, the books which they recommended; and as his finances did not enable him to accumulate a large library, he generally made copious extracts from such authors as he admired, and sometimes even transcribed a whole work, however voluminous. The variety and extent of his attainments were such as might be expected from his fine genius, cultivated with such intense, though perhaps desultory application. His companions looked up to him as a prodigy of knowledge, and received his opinions with the reverence due to an oracle.

As his mother was a zealous catholic, her house was much frequented by priests of that persuasion, who naturally directed the attention of our young student to ecclesiastical history, and to the peculiar claims and doctrines of the church of Rome. To this circumstance we are to ascribe the strong bias, which he retained through life, for books of polemical divinity and church history, with which he acquired such an extensive acquaintance as would have done honour to the most learned divines.

None of his other studies, however, were allowed to interfere with his drawing, which had always been his favourite employment. No day was allowed to pass without some effort of his pencil. At a very early age, he furnished designs, and is supposed likewise to have assisted in etching the engravings for a book of fables, or tales, which was reprinted by an Irish bookseller. These designs would of course be rude and imperfect; yet, as they were the first of his public attempts, the book which contains them, were it possible to procure it, could not fail to be interesting to those, who take pleasure in tracing the progress of genius. He does not appear to have attempted oil painting before the age of seventeen; but from that period till his depart-

ture for Dublin in his 22d year, he had finished several large paintings, the subjects of which sufficiently mark his taste for the *great* style, which he afterwards cultivated with such ardour and success.* It was during the same period that he produced that picture, which first attracted public notice, and brought him on a theatre more worthy of his talents than the mercantile city of Cork. It is founded on an old tradition relating to the arrival of St Patrick on the coast of Cashel in Ireland. The monarch of that district, induced by the fame of the saint to investigate the truth of the religion which he preached, professes his belief, and is admitted to baptism. The king steps before the priest, who holds in his hand a crozier, armed at the lower extremity with a spear. In planting this crozier into the ground, he accidentally pierces the foot of his royal convert. Absorbed in the duties of his office, he remains altogether ignorant of the accident, and pours the water on the head of the monarch, who preserves, during the whole ceremony, the most unruffled serenity of countenance, to which the mingled emotions of his attendants afford a very powerful contrast. One of his guards prepares, with uplifted battle-axe, to strike the saint to the ground, but is restrained by another who points in admiration to the king: of the female attendants, some kneel in solemn reverence before the priest, and others tremble in anxiety for their sovereign. When Barry had embodied this story on canvass, he set out with it for Dublin, accompanied by a friend and school-fellow; and arrived in that capital on the eve of a public exhibition of paintings. Though without a single recommendation, he obtained leave to exhibit his picture; and had the satisfaction to hear it universally applauded. The superior advantages which the capital afforded for his improvement and encouragement as a painter, made him relinquish all thoughts of returning to his native city.

The most material advantage which he derived from his residence in Dublin, was his acquaintance with Mr Burke, to whom he was introduced through the kindness of Dr Sleight, a physician in Cork, and a very enlightened amateur of the art of which Barry became so distinguished a master. In one of his first interviews with Mr Burke, an amusing incident took place, which could not fail to increase highly their mutual admiration and friendship. They were disputing on the subject of the arts as grounded on taste, when Barry, in opposition to Mr Burke's opinion, quoted the authority of a very able, though anonymous treatise, which had lately appeared. Mr Burke ridiculed the work as a mere theoretical romance, unworthy of attention, and useless as an authority. The contest became warm; and Barry's defence of this admired performance was rising even into rage, when Mr Burke, to appease him, acknowledged himself the author. Barry flew with transport to embrace him, and shewed him a copy of the *Essay on the Sublime and Beautiful*, which he had been at the pains to transcribe.

After residing about eight months in Dublin, he accompanied some of Mr Burke's family to London; where he was introduced, through the recommendation of his distinguished friend, to the most eminent painters, and engaged in an employment, which, though not very dignified, at least afforded him the means of sub-

sistence, and promised considerable professional improvement. That employment was to copy in oil colours drawings by Mr Stewart, the successor of Hogarth, better known by the name of Athenian Stewart. But to become a finished artist, it was necessary that he should study the works of the great Italian masters; and his generous patrons, Mr Edmund Burke, and his two brothers, provided him with the means of enjoying this essential advantage. Accordingly he set out for the Continent towards the latter end of the year 1765. During a residence of about ten months in Paris, he was very diligently employed in studying the best works in the various collections which that city contains, and in drawing after living subjects in St Luke's academy. From Paris he proceeded to Rome, where he continued nearly five years.

His mode of study, during his residence in that great emporium of the arts, was very different from the course generally pursued by young artists who resort thither for improvement. With an imagination capable of conceiving and of relishing whatever is grand and beautiful in art, he contemplated, with the most enthusiastic admiration, the noble specimens of both, which he found in the antique statues, and in the works of Michael Angelo, Raphael, and Titian. These inimitable models so completely occupied his attention, that, in one of his letters to Sir Joshua Reynolds, he informs him, that for near three years he had never employed himself for two hours on any thing else, except some little things of his own invention, and a piece of a figure of a Magdalen by Annibal Carracci. From these he endeavoured to exalt and refine his ideas of perfection in painting; and to catch the spirit which they breathed without condescending often to the mechanical drudgery of copying. We should be disposed, perhaps, to regret that more of his time was not devoted to his practical improvement in the art, were we not convinced that the very masterly criticisms which he has made on most of the paintings which he studied, and the excellent rules which he has deduced from them, are a much more valuable legacy to future artists, than the most finished productions, which, with the utmost attention to mechanical execution, his pencil could ever have produced.

Soon after his arrival in Rome, he was engaged in keen hostilities with the *Cicerones*. The contempt which they expressed for English artists, many of whom were his particular friends, offended at once his private feelings, and his national pride. His temper, naturally irritable, was often inflamed to rage, in the defence of his opinions, which, though generally correct, were frequently singular; while the knavery of the traffickers in antiquity, continually employed in duping his countrymen, drew from him the most passionate expressions of indignation. He became of course an object of general hatred to all the artists who resided at Rome; and his imagination was continually haunted with the idea of conspiracies formed to injure and depress him. By the mild and judicious remonstrances of his friends in London, he appears to have been in some measure restored to his temper and to peace; for in one of his letters we hear him say, that he spends his time agreeably with those whom he had formerly regarded with so much rancour and apprehension.

* These subjects were, *Aeneas escaping with his Family from the Flames of Troy; A dead Christ; Susanna and the Elders; Daniel in the Lion's Den; Abraham's Sacrifice,*

On his return to England in 1771, he determined to distinguish himself by some masterly production, which might at once establish his fame as a painter. The subject which he chose was Venus; and the public immediately recognized his amazing powers in embodying the most exquisite ideas of beauty and grace. Next year he produced a picture of Jupiter and Juno on Mount Ida, which was received as a favourable specimen of his talents for the great style. In the choice of his next subject, the death of General Wolfe, he was extremely unfortunate: for how could he expect to succeed in painting figures in the modern *costume*, which he had always affected to despise, as disguising the human form? The same contempt for the stiffness of modern dress rendered him extremely averse to portrait painting, which he considered, at any rate, as but an inferior branch of the art; but this can never apologise for his ingratitude and incivility to his steady friend and patron Mr Burke. Dr Brocklesby had expressed a desire to have a portrait of that gentleman painted by Barry; and Mr Burke, to gratify a friend whom he very highly respected, had presented himself for a sitting to Barry, at every leisure moment which he could command for near two years. Barry constantly refused or evaded his request, either pretending some indispensable engagement, or alleging that he could not begin the portrait without at least one day's previous intimation. In palliation of this ungracious conduct, it has been said, that "a kind of ill humour had at that time possessed Mr Barry, in consequence of the extreme intimacy of the Burkes with Sir J. Reynolds, which led him to suppose that these friends overlooked his merits, to aggrandize Sir Joshua's." This intended apology serves only to aggravate his offence. For surely if he could permit such a trifling circumstance to counterbalance for a moment his numerous obligations to the Burkes, he proved himself very unworthy of their kindness. Mr Burke naturally felt some resentment on the occasion, but conducted himself with a degree of prudence and moderation highly honourable to his character. After a mutual explanation, the affair was adjusted; and Barry, to make some atonement, finished the portrait in a style which proved that he needed only to apply his talents to portrait painting, to attain the highest eminence in that line.

His chief ambition, however, was to be engaged in some great public undertaking; as if emulous of the Italian masters, whose fame is in a manner identified with the celebrity of their grand national edifices. He therefore entered with eagerness into a proposal made to him, in conjunction with other artists, for decorating with paintings the interior of St Paul's. To his great mortification, the scheme was relinquished for want of the consent of the archbishop of Canterbury and the bishop of London. Another prospect soon opened, equally flattering to his ambition; for a proposal was made to the same artists, for ornamenting with historical and allegorical paintings the great room of the Society for the encouragement of arts, manufactures and commerce, in the Adelphi. The proposal was rejected by the artists themselves, and Barry was again disappointed.

During his residence in Rome, he had often been insulted and provoked by hearing the inability of British genius for the higher works of art, asserted and maintained from the authority of Montesquieu, Du Bos, and Winckelmann. He therefore employed the leisure which his disappointments now gave him, in drawing up an

"Inquiry into the Real and Imaginary Obstructions to the Acquisition of the Arts in England," which he published in 1775. In this able work, he very successfully confutes the absurd theories of the above-mentioned writers concerning the influence of climate; and proves from the history of the fine arts in Greece and Italy, that they flourish and decay, not according to the serenity or cloudiness of the sky, but as the moral feelings of the people are refined or depraved: to account for their slow progress in our own country, he reminds us, that when the rest of Europe was recovering a taste and feeling for the beauties of painting and sculpture, England was thrown out of the sphere of their attraction by the destructive fury of the reformers, by political revolutions and civil dissensions, and by the general turn of the public mind to mechanical inventions, to trade, manufactures, and commerce. He presented the treatise to Mr Burke, who, instead of receiving it with cold civility, as an illiberal critic has very injuriously asserted, (see the 32d number of the *Edinburgh Review*, art. 2.) returned the author a warm and flattering acknowledgment "for his early communication of his most ingenious performance, throughout the whole of which there are many fine thoughts and observations, very well conceived, and very powerfully and elegantly expressed."

As he had pledged himself in this inquiry for the capability of British genius to excel in the fine arts, he was anxious to redeem the pledge by some production of his own. He therefore undertook to execute by himself the paintings for the great room of the Society of Arts, on condition that he should not be interfered with, in the choice and prosecution of his subjects. The history of painting cannot afford an example of nobler and more disinterested ambition. When he made this proposal, his whole property amounted to only sixteen shillings; and during seven years of intense labour on this grand undertaking, he was obliged to earn the means of a scanty subsistence, by etching at night designs for the print-sellers, after being fatigued with painting all the day. Of the general design and particular subjects of these paintings, he has published a full explanation, to which we refer our readers. We shall merely mention, that they consisted of a series of six pictures, intended to illustrate the dependence of public and individual happiness upon the cultivation of the human faculties. Beginning with man in his savage state, full of inconvenience, imperfection, and misery, he carries him through the several gradations of culture and happiness, which, after our probation here, are finally attended with beatitude or misery. The first picture represents the story of Orpheus; the second a Harvest-home, or thanksgiving to Ceres and Bacchus; the third, the Victors at Olympia; the fourth, Navigation, or the triumph of the Thames; the fifth, the Distribution of Premiums in the Society of Arts, &c.; and the sixth Elysium, or the state of final retribution. When these paintings were finished, the society expressed their satisfaction by granting him two exhibitions, and voting him at different periods fifty guineas, their gold medal, two hundred guineas more, and a seat among themselves. The clear profits of the exhibitions amounted to upwards of 500*l.* and he received besides several handsome remunerations for portraits which he had copied into some of the pictures. The paintings excited the admiration of all who were qualified to judge of their merits. Jonas Hanway, it is said, on quitting

the room, demanded his shilling, and left a guinea in its place, as a payment more adequate to the pleasure which he had received. And Dr Johnson observed, that there was a grasp of mind displayed in them which could be found no where else.

The remaining incidents in Barry's life are only worth recording, as they serve to illustrate a truth, which cannot be too frequently inculcated, that moroseness of temper, and rudeness of manner, will always present an insuperable bar to the success of talents however splendid, and accomplishments however distinguished. We find Barry elected professor of painting in the royal academy; yet quarrelling with every one of his associates, accusing them of cabals and conspiracies against him, holding them up to the ridicule and detestation of his pupils, and at length attacking them publicly in an intemperate invective, which reduced them to the necessity of thrusting him from his chair—a chair which, with more temper, he might have filled with the highest honour to himself, and advantage to the art which he professed. We find him, after the pre-eminence of his genius had been universally acknowledged, deprived of almost every friend, sunk in the lowest indigence, scowling with malignity on mankind, whom he in general regarded as active enemies, and stung with the keenest torments of disappointed expectations and mortified pride. To such a frantic height did his fear of conspiracies reach, that he would not keep a servant, lest the active malice of his enemies should employ her as an instrument for his destruction. His house presented a picture of the most complete wretchedness; its walls sunk, and its windows broken; without even a bed that deserved the name; dirty, gloomy, and cold. Such a house seemed to offer but little temptation to plunderers; yet it was twice broken into, and robbed of several hundred pounds. The loss was made up to Barry by the munificence of the Earl of Radnor, and two gentlemen of the name of Hollis; but still his capital was too small to enable him to procure a more comfortable mansion. He had planned and begun a series of paintings to represent the progress of theology; but his narrow circumstances, and the want of proper accommodation, prevented him from proceeding with this design. In this situation he attracted the attention and pity of the Earl of Buchan, who set on foot a public subscription on his behalf, as the best mode of relieving his necessities without wounding his pride, which would probably have spurned at the idea of accepting any boon from individual benevolence. The subscription when closed amounted to about a thousand pounds, with which the friends of Mr Barry had just purchased an annuity, when their benevolent exertions were rendered useless by his death, which happened on the 22d February, 1806.

As an artist, Barry was distinguished by the grandeur of his conceptions, and the general magnificence of his designs. Glowing with the enthusiasm of genius, and impressed with an early conviction of the paramount importance of his art, he pursued, with indefatigable ardour, whatever could be made even remotely subservient to his professional improvement. He beheld the face of nature with the exquisite rapture of a poet; and while he contemplated its magnificent or tranquil scenes, felt his mind expand with the finest conceptions of grandeur and of beauty. He read, with all the interest of a kindred mind, the works of our most classical bards, and had completely digested and appro-

riated whatever was most pleasing or exalted in their descriptions. But his favourite study was history, which presented to his discriminating eye, all the varieties of character, action, and passion, and furnished valuable hints for his direction in the high style of historical painting. The monuments of Grecian sculpture, which he contemplated in Italy with almost idolatrous admiration, led him to the study of mythology, in which he acquired the skill and taste of an accomplished critic. And his early education, aided by the religious subjects of the Italian paintings, gave his mind so strong a bias for theology, that there was scarcely a fact in its history with which he was not acquainted. All these accomplishments were considered by himself as mere auxiliaries to his art; and their advantage is sufficiently apparent in his paintings, which, however deficient in correctness and execution, are allowed by all to be almost unrivalled in the sublimity of idea, and vast reach of thought expressed in their design. But his varied acquisitions appear with still more admirable effect in his writings, which contain more acute and able criticisms on the various styles and productions of the great masters in painting, and more judicious rules for the practice of that art, than any work of the same kind that has ever been given to the world. How much is it to be regretted, that such an artist had not been enabled, by the independence of his circumstances, to follow out, without distraction, his own magnificent ideas; or that the sternness and irritability of his temper prevented him from reaping the full advantage of his superiority! In justice to his character, however, we must observe, that though thus repulsive and irascible, he was by no means deficient in the better qualities of the heart. He was susceptible of the warmest friendship; and had not his mind been soured by dependence and misfortune, might have been a cheerful and engaging companion. His honesty, his candour, and his sincerity, were proverbial; and his desires were so moderate and well regulated, that he could submit, without repining, to privations, which few men in polished life could even sustain.

His principal paintings were, a picture of Adam and Eve, Venus, Jupiter and Juno, and the paintings in the great room in the Society of Arts. His writings are, Lectures on Painting; Observations on different Works of Art in France and Italy; Fragment on the Story and Painting of Pandora; An Inquiry into the Real and Imaginary Obstructions to the Acquisition of the Arts in England; A Letter to the Dilettanti Society; An account of a Series of Pictures in the Great Room of the Society of Arts, &c.; A Letter to the President, Vice Presidents, and the rest of the Noblemen and Gentlemen of the Society for the encouragement of Arts, &c. See the *Works* of the late James Barry, Esq. with a sketch of his life prefixed. (k)

BARSALLI, a kingdom of Africa, on the river Gambia, inhabited by the Jaloffs. This kingdom is not mentioned by Durand, in his enumeration of the different kingdoms on the north and south banks of the Gambia, and must therefore be included in some other state. See an account of Barsalli in the *Mod. Univers. Hist.* vol. xiv. p. 104. See also Durand's *Voyage to Senegal*, chap. iv. (w)

BARTER, or **BARTAR**, in Arithmetic, is the method of finding the value or quantity of one commodity which is to be given in exchange for another. Questions of this kind are solved either by the Rule of Three, or Practice.

Exam. 1. How many yards of broad-cloth at 17s. 6d. per yard, must be given in exchange for 360 yards of linen at 3s. 6d. per yard?

Since the value of the two commodities is supposed to be equal, it is evident that we must first compute the value of 360 yards at 3s. 6d. per yard, and then find how many yards, at 17s. 6d. per yard, can be purchased for the amount.

Yd.	Yds.	Sh.	Sh.	Sh.	Yds.
1	: 360	: 3s.	17.5	: 1260	: 1
		360		1	
		2100	17.5	1260	(72 yards)
		105		1225	
		1260 Sh.		350	
				350	

The above question might also have been solved by one stating, thus :

Sh.	Sh.	Yds.	Yds.
17.5	: 3.5	: 1260	: 72

Hence it may be inferred, in general, that if the quantity of one commodity be multiplied by its rate, the product, divided by the rate of the other commodity, will give its quantity.

Ex. 2. At how much per pound was cotton rated when 1036lbs. of it were exchanged for 6 cwt. 3 qrs. 21 $\frac{1}{2}$ lb. of sugar, at 2l. 16s. per cwt. and 21l. : 11 : 8 in money?

BARTHELEMY, JEAN JAQUES, a French Abbé, eminently distinguished by his literary attainments and virtues. He was born in Jan. 1716, at Cassis, a small seaport in Provence. Being destined for the church, he was sent at twelve years of age to study at Marseilles, where he was admitted into the college of the oratory,

under the tuition of father Renaud, a man of learning and taste, who became warmly attached to his young pupil. It became necessary for him, however, to quit this seminary, on account of an ordinance of the bishop of Marseilles, by which students of the oratory were refused admission to holy orders. With much regret, therefore, Barthelemy was obliged to quit his esteemed preceptors, and to betake himself to the study of philosophy and theology under the Jesuits.

Dissatisfied, however, with the plan adopted by his new masters, he determined to follow a method of his own, in private; and applied to the study of the ancient languages, as well as of the Hebrew, Chaldean, and Syriac, with such indefatigable perseverance, that it had nearly cost him his life. Having recovered from a dangerous illness, brought on by too intense an application to study, he at length entered the seminary, where he received the clerical tonsure. Here he made such progress in the study of Arabic, by the assistance of a young Maronite, who had been educated at Rome, that he was able to deliver some sermons in that language, composed by a Jesuit belonging to the *Propaganda*, to an assembly of Maronites, Armenians, and other Catholic Arabians, then at Marseilles. He also gave another uncommon specimen of his proficiency in the oriental languages; for, at the age of twenty-one, at the request of some of the principal merchants of Marseilles, he, with great applause, conducted a learned dialogue, with an itinerant Jewish rabbin, who had become a professor of the Christian religion, and claimed to be deeply skilled in the languages of the East.

Having finished his studies at Marseilles, Barthelemy retired to his family at Aubagne; but was accustomed to repair occasionally to his former residence, in order to enjoy the society of the academicians, and other learned men residing there. Among those to whom he more particularly attached himself, was a M. Cary, the possessor of a valuable collection of books, and fine cabinet of medals; so that now he laid the foundation for that knowledge and taste in antiquities for which he was afterwards so justly celebrated. It was in 1744 that Barthelemy repaired to Paris, with a view of devoting himself entirely to literature. He was furnished with a letter of introduction to M. de Boze, keeper of the royal cabinet of medals, and perpetual secretary to the academy of inscriptions and belles lettres. By this eminent antiquarian he was warmly patronised, and introduced to the acquaintance of the most distinguished members of the three academies, who dined twice a week at his apartments. In such society the taste and knowledge of Barthelemy could not fail to be materially improved.

In consequence of the declining health, and increasing age of M. de Boze, an associate became necessary, to aid him in the labour of completing the royal cabinet of medals; and Barthelemy was selected for this office, in preference to M. Bastie, a learned member of the academy of inscriptions. From this moment he devoted the whole of his attention and care to the elucidation of that branch of study which had now become his official employment. In 1747, he succeeded M. Burette as associate to the academy of inscriptions; M. le Beau, who had been a candidate, declining a competition with so eminent an antiquarian. When he was afterwards nominated by the minister to be secretary to the academy, he waved the nomination in favour of M. le Beau, as an acknowledgment of his former liberality. In return, M. le Beau, on resigning this office, gave his in-

(A)

terest to Barthelemy, who was appointed his successor; and thus did these distinguished rivals vie with each other in the exercise of a liberality which reflected equal honour upon both. On the death of M. de Boze in 1753, the Abbé Barthelemy succeeded him as principal keeper of the medals; and during this interval, he had enriched the memoirs of the academy with several valuable papers relative to ancient monuments; and, in particular, an interesting dissertation on the inscriptions found at Palmyra by the English travellers.

At this period Barthelemy was particularly patronised by M. de Stainville, afterwards better known under the title of the Duc de Choiseul. This gentleman, as well as his lady, who was young and beautiful, were great admirers of the fine arts, and found in Barthelemy a man of letters, in whose conversation and manners they enjoyed a constant gratification. In 1754, M. de Stainville having proceeded with his family to Rome, in the capacity of ambassador, was followed by Barthelemy, who was distinguished by the particular notice of Benedict XIV., who then wore the tiara, and was himself an accomplished scholar. From Rome the Abbé proceeded to Naples, then rendered peculiarly interesting to antiquarians by the recent discovery of the subterranean treasures of Pompeii. In the museum of Portici, amidst numerous interesting remains of antiquity, the attention of Barthelemy was peculiarly attracted by the manuscripts rescued from the ruins of Herculaneum; of which four or five hundred had been recovered; but all of them remained in their original forlorn state, except two or three that had been unrolled, and commented upon by the learned Mazocchi. Barthelemy used his most strenuous efforts to engage the Neapolitan court to expedite the examination of the remaining manuscripts; and succeeded in persuading the Marquis Caraccioli to enter into his views; but this desirable object was frustrated by the death of that minister a few years afterwards.

Barthelemy was also extremely desirous of presenting the learned men in France with a specimen of the ancient writing employed in the Greek manuscripts. He was informed, however, by the guardians of the treasures at Portici, that they were expressly enjoined to communicate nothing. On this Barthelemy solicited permission to look, for a few minutes only, on a page of a manuscript which had been cut from top to bottom since its discovery. It contained 28 lines, which our antiquarian read over six different times with extreme attention. He then retired to a corner, and transcribed the precious fragment from memory; after which he again examined the manuscript in order to render his copy more correct. Having by this stratagem rendered himself master of a *fac-simile* of the MS. which related to the persecution of the Greek philosophers during the time of Pericles, he immediately transmitted his literary plunder to the academy of belles lettres, with an injunction of secrecy, in order that the keepers of the museum might escape from blame. On his return to Rome he acquired great applause for a new and ingenious explanation of the famous Mosaic at Preneste, or Patestrina, which, according to him, related not to Sylla, but to Adrian.

In 1757 we find Barthelemy escorting the lady of M. de Stainville to Vienna, at which court that gentleman had been appointed ambassador. Here he had the self-denial to refuse an offer of his friend and patron to procure him permission to visit Greece and the ports

of the Mediterranean, at the king's expense; because he conceived it inconsistent with the calls of his duty at Paris, as custodian of the royal medals. When in 1758 M. de Stainville was nominated minister for foreign affairs, and became Duc de Choiseul, he immediately exerted himself to provide for Barthelemy, for whom he procured pensions to a considerable amount, and among others an annuity of 5000 livres on the Mercury. The Abbé himself had the modesty to name 6000 livres a year, as the sum that would make him easy for life. But before M. de Choiseul was obliged to retire from power in 1771, his income amounted to 1200*l.* sterling per annum, of which, however, he distributed more than a fourth part among indigent men of letters. He also educated and established three nephews, one of whom afterwards made a considerable figure on the stage of revolutionary politics as a member of the directory; and appears to have inherited many of the virtues and talents of his ancestor. He at the same time supported his relations in Provence, and selected a noble library, which he was obliged to dispose of some time before his death.

When the Duc de Choiseul was disgraced and banished to his seat at Chanteloupe, in order to make way for his enemy the Duc d'Aiguillon, Barthelemy became the companion of his exile, and offered the resignation of his secretaryship of the Swiss guards, because his patron's commission as colonel-general was demanded from him. An arrangement, however, was made, by which the Abbé's revenue received no material diminution; and thus for twenty years of his life he enjoyed a state of literary affluence. In advanced age, however, he found himself reduced, by the suppression of places and pensions, to mere necessities; but he supported this reverse of fortune with the greatest equanimity and good humour; and was never heard to complain, nor did he even seem to perceive the change.

In 1788 appeared his celebrated work, entitled, *Voyage du jeune Anacharsis en Grèce, dans le milieu du quatrième siècle avant l'ère Chrétienne*, which had occupied his leisure hours during an uninterrupted succession of 30 years; and in 1789 he became a candidate for a chair in the French academy, to which, in consequence of his high reputation, he was elected by general acclamation. In the following year he declined an offer of the place of librarian to the king, apprehensive that it might interfere with his literary occupations, and his labours in the cabinet of medals, in which he had now got an useful associate in his nephew Barthelemy Courcy, who was conjoined with him in the office in 1768.

At that gloomy period of the French revolution, when virtue and talents were proscribed and persecuted, the age, declining health, and long services of Barthelemy, could not save him from the suspicions and insults of the wretches then in power. On the 30th of August, 1793, a warrant of apprehension was issued against him and his nephew; and on the 2d of September the officers of justice made intimation of this to the Abbé, who happened to be then at the house of Madame de Choiseul. With the greatest calmness, he immediately submitted to the order, and was conducted to the Magdorettes, where he found his nephew before him. His imprisonment, however, was not of long duration; for on the representation of his friend Madame de Choiseul, orders were issued for his liberation in the course of that very evening: and such was the singular compo-

sure of his mind, that when the warrant for his delivery arrived, he was found in the enjoyment of a profound repose. He was soon after offered the place of national librarian, by way of reparation, it should seem, for this unmerited aggression; but his increasing infirmities were a sufficient apology for his refusal.

His decay was gradual, but seems to have been accelerated by the rigorous winter of 1795. After a short confinement, he expired on the 30th of April of that year, without any struggle, and apparently without experiencing any pain. He retained his faculties to the last moment; and only a few hours before his death was engaged in reading his favourite Horace, till his hands became so numbed that they could no longer support the book. Thus died, in the 80th year of his age, the Abbé Barthelemy, whose virtues, erudition, and fine taste, entitle him to be considered as a principal ornament of the age in which he lived. He is said, in his person and countenance, to have exhibited much of the noble and simple character of that antique, which it was his chief delight to study; and his bust, admirably sculptured by Houdon, has an expression that entitles it to stand by the side of that of Plato or Xenocrates.

The royal cabinet of medals was greatly enlarged and embellished under the superintendance of Barthelemy. He confined his inquiries almost entirely to the coins of antiquity, considering modern medals as an object of very subordinate importance. He found in the cabinet about twenty thousand ancient medals, and left in it no less than forty thousand; having, at different times, examined, as he declared to a friend, not fewer than four hundred thousand ancient coins. A collection of miscellaneous pieces of the Abbé Barthelemy appeared at Paris in 1798, in 2 vols. 8vo.; in which we find, among other interesting performances, an elegant and classical tale, entitled *Capté and Polydore*, of which the fable relates to that period of Grecian history, when the Athenians were subjected to the cruel and disgraceful tribute of an annual supply of youths and virgins, to be devoured by the Minotaur of Cræte. But by far the most important literary labour of Barthelemy was his *Travels of the young Anacharsis in Greece*, which, as we have said, was the employment of his leisure hours for thirty years. The young Anacharsis is a supposed son of the Scythian sage of the same name, and is represented as visiting Greece, in the year 563 B. C. in order to make himself acquainted with the arts, the literature, and eminent characters of that celebrated country, at this the most brilliant era of its history. The young Scythian fixes his residence at Athens, whence he makes excursions, not only to the other Grecian cities, but also to Egypt, Asia Minor, Persia, and the islands of the Ægean Sea. He becomes familiar with Plato, Aristippus, Epaminondas, and every other illustrious character of the age; and gives minute details of the prevailing systems of philosophy, forms of political administration, models of the fine arts, and every other particular that is likely to be interesting in the internal economy of the Grecian states. The narrative of Anacharsis is addressed to Arsames and Phedime, a Persian satrap and his lady, whose characters are meant as portraits of the duke and duchess of Choiseul; and the authority of the most approved ancient writers is uniformly quoted for every fact and detail, that makes a conspicuous figure in the work. Thus, under the form of an ingenious fiction, Barthelemy has contrived to produce a most instructive commentary on his favourite subject, the antiquities of

Greece; and by the elegance of his style, the liveliness of his narrative, and the justness of his reflections, he has rendered his work attractive to the unlearned, as well as to the learned reader. An introductory discourse is prefixed, in which a rapid, but luminous, view is given of the previous periods of Grecian history; and maps and engravings are annexed, together with a variety of useful tables, in order to render the work completely illustrative of the geography and antiquities of ancient Greece. The great estimation in which this work is held, has been proved by the variety of editions, as well as translations into different languages which it has undergone; but it is perhaps to be regretted, after all, that the learned author has so completely fettered himself by the authority of ancient writers, that he has on no occasion given the reins to his imagination, or assigned any fictitious adventures to his hero Anacharsis, by which the attention of the reader might be occasionally relieved, and a greater appearance of reality conferred upon the whole. The young Anacharsis is, in fact, a completely inanimate picture, and interests the reader in no other manner, than as the connecting vehicle, by which, whatever relates to the arts, science, or literature of ancient Greece, is digested into one harmonious whole. It was suggested, soon after the appearance of the travels of the young Anacharsis, that the hint of the work was taken from a book published at Cambridge, under the title of *Athenian Letters*, and consisting of the imaginary correspondence of a set of Grecians, the supposed cotemporaries of Socrates, Pericles, and Plato. This, however, the Abbé Barthelemy expressly denied to M. Dutens; assuring that gentleman that he had never heard of the *Athenian Letters* till after the publication of his work. Were it necessary to seek for a model that might have suggested this celebrated production, we should have been more disposed to select the *Travels of Cyrus* of the Chevalier Ramsey, than the *Athenian Letters*. (m)

BARTHOLINE, THOMAS, a celebrated Danish anatomist, was the second son of Caspar Bartholine, a learned clergyman at Melanoe in Sweden, and the author of numerous works on medicine and natural history. He was born at Copenhagen in the year 1616, and after receiving his classical education in that city, he travelled through the greater part of Europe. From Leyden, where he began his medical studies, he went successively to Paris, Montpellier, and Padua. After an absence of eight years, he returned to Copenhagen; and from thence he went to visit Basle, where he was honoured with the degree of doctor of medicine in 1645. The first public situation which he held was the professorship of mathematics at Copenhagen, from which he was translated, in 1647, to the chair of medicine, which he filled with great credit to himself, and with great advantage to the science. Nearly at the same time with Jolliff and Olaus Rudbeck, he discovered the lymphatics while dissecting the bodies of live dogs, and he perceived the same vessels in the liver of a fish. (See *HISTORY OF ANATOMY*). Fatigued with the duties of a public life, he retired, in 1661, to his estate at Hoggestatt, where he continued nine years, prosecuting with ardour his favourite studies. By some unfortunate accident, his house caught fire in the year 1670, and the whole of his manuscripts and valuable library being completely consumed, he was compelled to resume the active labours of his youth. The king of Denmark created him his physician and aulic counsellor; and he

was appointed chief inspector of the library of the university. These new appointments, and the sympathy of his numerous friends and correspondents, soon consoled him for his heavy loss, and stimulated him with the utmost zeal for the prosecution of his labours. He died in the year 1680, leaving behind him a family of five sons and three daughters.

His principal works are, *Anatomica Aneurismatis dissecti historia*, Panormi, 1644, 8vo. *De Angina puerorum Campaniæ, Siciliæque epidemica*, Neapoli, 1646, 8vo. *De Luce Hominum et Brutorum, et de rarioribus et admirandis herbis que noctu lucent*, Leidæ, 1647. *Vasa lymphatica, nuper Hassniæ in animantibus inventa, et in homine*, Hassniæ, 1653, 9to. *Catalogus operum Suorum, hactenus editorum, exactæ cum observationibus variis de nivis usu medico*, Hassniæ, 1661, 8vo. *Domus Anatomica Hassniensis*, 1662, 8vo. *Centuria Quatuor epistolarum Medicarum*, republished at the Hague in 1740, in 5 vols. 8vo. *De insolitis partibus humani vius*, Hass. 1664, 8vo. *Historiæ Anatomiciæ*, Cent. vi. *Acta Medica et Philosophica Hassniensis*, 4 vols. 9to.—See Vander Linden *De Scriptis Medicis*. Haller *Biblioth. Anatom.* and the *Biblioth. Med. Pract. et Chirurg.* (q)

BARTHOLOMEW, an Apostle, and a name which signifies the son of Tholomew. That it was customary among the Jews to name their children in this manner, appears from Bartimeus being interpreted *the son of Timeus*, Mark x. 46.; and Simon Peter, who is called Bar-jona, Matt. xvi. 17., is in John xxi. 15. named Simon son of Jonas.

It is generally believed, that Bartholomew is the same with Nathanael, the one his proper, the other his patronymical name; and it is well known to have been customary, among the Jews, to give several names to the same person. In support of this opinion, the following circumstances may be adduced. As John is the only evangelist who makes mention of Nathanael, so he never speaks of Bartholomew, which it is probable he would have done, had they not been one and the same person. When the twelve apostles are named, Philip and Bartholomew are invariably joined together; and, as Philip was the person who first brought Nathanael to Jesus, it is highly probable that Bartholomew is the same person who is by John called Nathanael. When our Lord appeared, after his resurrection, to several of his disciples at the sea of Tiberias, Nathanael is mentioned among the number; and all the rest named upon that occasion were apostles. (*John* xxi. 1, 2.) From those circumstances, it is more than probable that Nathanael was one of the apostles, and that he is the same with Bartholomew.

In the New Testament no mention is made of his station or employment, except that he accompanied Simon Peter, and others, when they went a fishing on the sea of Tiberias. Several of the early fathers of the church tell us, that he was of Cana in Galilee. (as was also Nathanael,) and that he was skilled in the law. Eusebius says, that he preached Christianity, with great success, in India; and that he carried thither St Matthew's gospel in Hebrew, which was preserved in that country with great care, as a most valuable treasure. From thence he went into the more northern and western parts of Asia, then into Lycæonia, and at last came to Albanople, a city of the greater Armenia. Having converted the king and queen of that country to christianity, and having persuaded many of the people to relinquish their idolatrous worship, the priests were so in-

censed against him, that they prevailed upon the king's brother to deliver him into their hands; and caused him first to be flayed, and then beheaded, or crucified. See Cave's *Lives of the Apostles*; Augustine *Tract. in Joan.* vii.; Euseb. *Hist.* l. v. c. 10. (A. F.)

BARTHOLOMEW, SAINT, one of the French Caribbee islands in the West Indies, situated to the north of St Christophers. This island, which is about 24 miles in circuit, was peopled by the French in 1648. It fell into the hands of the English in 1689, but was restored to France by the treaty of Ryswick. It was ceded in 1785 to the Swedes, to whom it now belongs. Though the soil is rather poor, it produces cotton, the plantations of which have been very successful, tobacco, cassava, and various kinds of wood. A peculiar sort of limestone found here is exported to the neighbouring islands. The principal exports are cotton, lignum vitæ, drugs, and iron wood, and it is supplied from America with flour, dried fish, and fresh and salt provisions. Gustavia, the only town in the colony, is inhabited by Swedes, English, French, Danes, and Americans: The houses are made of wood, and many of them built on stone pillars. The only harbour in the island is Le Carénage, near Gustavia. It contains about 100 vessels, but though the moorings are excellent, it will admit only such vessels as draw below nine feet of water. West Long. 62° 48'. North Lat. 17° 53'. See *A Voyage to St Martin's, &c. undertaken at the Expense of the Academy of Sciences at Stockholm.* (j)

BARYTES. See **CHEMISTRY Index.**

BASALT, a species of the trap family. See **GEOGNOSEY** and **ORVTOGNOSEY.** (r)

BASE, in Anatomy, a term used by anatomists in a very vague manner in their descriptions of the animal body. Sometimes it refers to situation in respect of some other part, as *the base of the cranium, i. e.* its lower part in the usual attitude of the human body; *the base of the brain*, or that part of the encephalon which rests on the lower part of the cranium. Sometimes it is employed to denote a certain side of a triangular organ, as *the base of the scapula, i. e.* that side which is next the spine; *the base of the heart*, or that side opposite the point or apex. (f)

BASE. See **CHEMISTRY, GEOMETRY, and MUSIC.**

BASELLA, a genus of plants of the class Pentandria, and order Trigynia. See **BOTANY.** (z)

BASHAW, or more properly **PACHA**,* a person ap-

* We would prefer *Bashaw*, because the Turks cannot articulate the letter *p*. We do not understand the Turkish language, but we have heard Turks speak Italian, and observed, that whenever the letter *p* occurs in any word, they pronounce it like a *b*. Thus, instead of *il popolo*, they say *il bobolo*. It is probable therefore that they say *Bashaw*, and not *Pacha*. Besides, this word was always written *Dashaw* in English, until very lately, when a singular rage has prevailed for innovation in the established spelling of foreign words, and particularly of those of Oriental derivation. The first that underwent a similar change, we think, was *Alcoran*; it was discovered that the particle *al* in the Arabic idiom answers to our article *the*, and therefore it was thought proper no longer to say the *Alcoran*, but the

pointed to the government of a province, district, or city, within the dominions of the Grand Seignior. When the successive conquests of the sultans had rendered their empire too extensive to be controlled by their own immediate vigilance, they entrusted the government of the remote provinces to viceroys, who might enforce the imperial mandates, and convey to the imperial exchequer the revenues of their respective departments. Of these viceroys, or bashaws, there are two orders, invested with different degrees of rank and authority. The first order are called bashaws with three tails, because three horse tails wave on their military standards; the second are named bashaws with two tails, for they are not allowed to adorn their standards with more than two such streamers. The authority of the bashaw with three tails is, in their respective governments, nearly as unlimited and despotic, as that of the monarch whom they represent. The military and executive power are united in their persons; and the lives and properties of all within their department are almost entirely at their disposal. They maintain a military establishment suitable to the extent, revenues, or the situation of their provinces; and when summoned by the sovereign, or when the frontier is menaced, they take the field at the head of their respective armies. In the administration of civil justice, however, the bashaws are not allowed to interfere. Every case of civil litigation is decided by the CADIS or judges, who, by a wise regulation, are made entirely independent of the viceroys. The bashaws with two tails have a less extensive department, and more limited power. They cannot inflict death without the sentence of law; and though they have the command of the armed force within their district, they are obliged in the field to range their troops under the standard of a bashaw with three tails, and to

submit to his commands. In extensive government the bashaws have likewise a number of delegates, who command, in their different spheres, with as despotism as the bashaw or the sultan themselves. Nothing can be conceived more galling and oppressive than this systematic gradation of despotism. The sword of the monarch is thus transferred into the hands of the meanest underling; and is always wielded with more dreadful effect, as it is more circumscribed in its range.

The abuses which prevail in all the bashawlics are dreadful beyond expression. As the great end of these governments is to convey the riches of the empire into the coffers of the grand seignior, it becomes of course the first obligation of a bashaw to levy and transmit the tribute imposed on his particular district. The means of doing this are left entirely to his own discretion; nor is it possible for him to be very delicate in the exercise of his authority. Obligated to purchase his appointment from the vizir, or some other person of influence, by bidding higher than all his competitors, he is of course eager to indemnify himself by his exactions. Besides, he finds it necessary still to advance considerable sums to the court, in order to obtain promotion, or even security; and therefore he has recourse to every expedient for raising money; and as he is uncertain how long he may retain his office, the readiest expedients are always preferred. The mode generally adopted is, to farm out the revenues of the bashawlic to some of the principal inhabitants at an exorbitant rent: these again subdivide them into smaller lots at an increased sum; and thus the system, becoming more oppressive as it descends, reaches even to the meanest hamlets. By this system a considerable proportion of the population are interested in increasing the public burdens; and as they are supported in their extortions by state-authority, the wretched inhabitants must submit to them without murmuring. The inevitable and immediate tendency of these extortions is to ruin and impoverish the country, by repressing the spirit of industry and improvement.

Koran. But it was not observed, that we also say *Algebra, Almanac, alkali, alcohol, alkermes,* &c. and that there could be no reason for striking out the article of one word of Arabic origin and leaving it in the others; and that if it were struck out of all, it would introduce a ridiculous and useless confusion into our own language. We do not mean to say that etymology, and a similarity of sound, are not fit considerations to be attended to when words, and particularly proper names, are for the first time introduced from one language into another, but we do not think that they are of sufficient importance to authorize the alteration of a word which has long been in use among us, and is become in a manner vernacular. We are sorry to observe, however, that almost every traveller who visits a distant country, to shew his intimate acquaintance with its idiom, has the goodness to furnish us with new modes of spelling the names of persons and places. Thus we must no longer call the prophet of Mecca, as heretofore, *Mahomet*, but *Mohammed*, nor his followers, as we used to do, *Mussulmen*, but *Moslems*; and the well known name of *Cairo*, by which we were wont to distinguish the capital of modern Egypt, must be changed, it seems, for *Qairo*, *Khairo*, or *El Khair*. At this rate, we may soon expect to see this innovating system applied to all foreign proper names without exception, and, under pretence of coming nearer to the genuine pronunciation of each word, we shall probably have *Larroshell*, *Nongt* and *Parree*, instead of the long established denominations of *Rochel*, *Nantz*, and *Paris*. DU PONCEAU.

The extensive power of the bashaws naturally makes them ambitious to render it permanent; while the jealous policy of the sultan induces him to remove them frequently, that they may not have time to form such connections as may enable them to assert their independence. This precarious tenure by which the bashawlics are held, is productive of many evils. If the viceroy be of a bold and aspiring temper, his province is harassed by wars occasioned by his rebellion. At all events, they regard their governments as mere transient possessions, and are therefore eager to extort from them every temporary advantage, regardless of the sufferings of the people, who look forward, with a kind of desponding anxiety, to a change, which may only perhaps increase their oppression. Besides, in the frequent journeys of the bashaws, the intermediate towns are subjected to great expense, and the fields and villages are ravaged by disorderly troops. Hence every part of the Ottoman empire, at any distance from the capital, presents a scene of the most complete desolation:—large tracts of country lying uncultivated, hamlets and villages uninhabited and in ruins.

Though the name bashaw is properly applied to a governor of a province, it is sometimes given, as a title of respect, to people of distinction, although they hold no such office. It is in that case placed after the proper name, and is equivalent to the French *monseigneur*.

or to *your excellence, your honour, &c.* in English. For some interesting information relative to the bashaws, see Volney's *Voyage en Syrie et en Egypte*, tom. i. chap. x. vol. ii. chap. xxxiii. Olivier's *Voyage Dans l'Empire Ottoman*, &c. chap. xvii. Russel's *Aleppo*, vol. i. book ii. chap. vii. See also Guér's *Mœurs et Usages des Turcs*, tom. ii. lib. x. Savary's *Lettres sur Egypte*, tom. ii. let. 15. (u)

BASHEE, or BASHI ISLANDS, a group of six or seven islands in the Chinese sea, situated between the island of Formosa and the Philippine Isles. The five principal islands are Grafton, Monmouth, Orange, Bashee, and the Isle of Goats. The islands of Monmouth and Grafton are well peopled, but the island of Bashee, which is about two leagues in diameter, contains only one village. The mountains are very stony, but the valleys are very fertile, and are watered with numerous rivulets. The women take the charge of the plantations, while the men employ themselves chiefly in fishing. The principal productions of these islands are, bananas, pine-apples, pumpkins, sugar canes, and cotton. Potatoes and yams, which grow in considerable quantities, serve the inhabitants for bread. The only articles imported into the Bashee islands are, iron and buffalo hides, which it is probable they obtain from Luzon, the principal island of the Philippines. East Long. 122°, North Lat. 23½°. (w)

BASHKIRS, a people of the Russian empire, scattered along the banks of the Volga and Ural. Their country forms a part of the ancient Bulgaria; and they seem to be descended partly from the Bulgars, and partly from the Nogay tartars. Without any fixed abodes, they wandered formerly along the southern regions of Siberia, till the oppression of the Siberian khans obliged them to confine themselves within their present territories, and to court the protection of the khans of Kazania. When that government was subverted by Czar Ivan II., they voluntarily assumed the Russian yoke; though their subsequent revolts proved that their submission proceeded entirely from necessity. They now belong to the governments of Ufa and Perme; and consisted about forty years ago of 2700 families. They are divided into 34 *wolosts*, or tribes, each of which elects for itself one, and sometimes two, ancients or *starschinis*. In their manners they differ but little from the other Tartars. Fond of the pastoral life, their principal wealth consists in their flocks, and in herds of cattle, horses, and camels. They pay particular attention to the management of bees, in which they are very successful. Their hives, which, in general, are merely cavities in trees, are defended by many ingenious contrivances from the attacks of the bears. A very small proportion of their lands is under tillage, and oats and barley are the only kinds of grain which they rear. These, with the milk and flesh of their cattle, are the chief articles of their subsistence.

The Bashkirs still retain a strong antipathy against the Russians, insomuch that they consider it a kind of national duty, when they are employed by them as guides, to conduct them through marshes, and other places the most impracticable that they can find. The Russians, in their turn, are extremely jealous of the Bashkirs, and will not permit them to dwell on the mountains, that they may be able to keep a watchful eye over their conduct.

The troops of this nation are all horsemen, and are remarkably well mounted. They are armed with a bow,

a lance, a helmet, and a coat of mail; and are besides provided by the Russians with sabres, muskets, and pistols. In drawing the bow they display uncommon skill, and manage their horses with great dexterity. In times of war they are obliged to furnish the Russian army with 3000 cavalry, which are divided into 30 troops, each consisting of 100 men. They are an indolent, slovenly, and simple people; but are hospitable, lively, and brave. See Chantreaux' *Travels*, Tooke's *View of the Russian Empire*, *Voyage de Pallas*, *Voyage de Gmelin*, &c. (u)

BASIL, SAINT, surnamed the Great, was born in Cæsarea, in the year 326, and became bishop of that city. Having studied at Constantinople, he went to Athens to perfect himself in that school of science; and his studies being completed, he returned to his native country in 355, and taught rhetoric. While he resided at Athens, he became acquainted with Julian, afterwards surnamed the Apostate, who was also engaged in the study of eloquence in that celebrated city. With him Basil read not only the profane authors, but also the books of the Holy Scriptures: Julian carefully concealed from him his real sentiments of the sacred writings. But when raised to the imperial throne, he threw off the mask, and filled his court with heathen philosophers, and magicians from all parts of the world. Basil manfully rejected his repeated solicitations to reside at his court, though accompanied with the warmest professions of friendship. He afterwards retired to the monasteries in Syria, Egypt, and Libya, where he became so fond of the monastic life, that he embraced it on his return to Pontus and Cappadocia. Having received the order of priesthood from Eusebius bishop of Cæsarea, he retired into religious solitude; but, in that state, he continued only about three years; for upon the death of that bishop in 370, he reluctantly allowed himself to be appointed his successor. No sooner was he seated in the episcopal chair, than the emperor Valens began to persecute him, and even threatened to banish him from Cæsarea, because he refused to embrace the tenets of the Arians. The emperor sent to him a prefect, who was commanded, either by entreaty or menace, to obtain his compliance. The pious Basil peremptorily refused. The prefect having reminded him of the danger to which he was exposed, of having *his land, his liberty, and even his life, sacrificed* by the disappointed emperor, he made the following noble reply: "He who has nothing, dreads not *confiscation*. Every place being alike indifferent to me, how can any *exile* be a punishment? If you *imprison* me, I shall enjoy more pleasure than at the court of Valens. And with respect to *death*, it will be to me a blessing, because it will unite me to the Almighty." The prefect was astonished, and remarked that none had ever presumed to speak to him in that manner. "Probably," replied Basil, "you never before saw a *bishop!*" Finding it impossible to bend him from his resolution, the emperor ceased to molest him; and Basil then began to use all that influence, which his high character and office had so justly acquired, in endeavouring to compose the differences which at that time subsisted betwixt the eastern and western churches; but unhappily his well meant efforts proved ineffectual, and that contest was not terminated till after his death. He also took a share in the various controversies which arose in that period of the church, and died in the year 379. "In point of genius, controversial skill, and a rich and flowing eloquence;"

says Mosheim, "he was surpassed by very few in that century." There have been several editions of his works in Greek and Latin. The last and best is that published at Paris in 3 vols. folio, in 1721, by Julien Garner, a learned benedictine. See *Mosheim*, vol. i. p. 358. *Ant. Univ. Hist.* vol. xvi. p. 242. *Biog. Diet.* vol. ii. p. 75. (A. F.)

BASILAN, or **BASSEILAN**, one of the Philippine islands, situated about three leagues from the south-west extremity of Mindanao. This rich and fertile island, which is called the Garden, produces plantain trees, sugar canes, and rice, in great abundance; and great quantities of fish of every kind are found on its coasts. Fine tortoises are caught for the sake of their shells, and two kinds of jet are found in great plenty. There are numbers of wild boars and stags in the forests. Pearls are fished on the coast, and considerable quantities of ambergris are thrown on shore. Basilan is the only one of the Philippine isles where elephants are found. East Long. 121° 50', North Lat. 6° 25'. (w)

BASILAR, in Anatomy, a term derived from *base*, and generally employed to distinguish those vessels which supply the base of the brain, as the *basilar artery*. It has, of late, been extended, by Dr Barclay, to indicate the aspect or position of parts of the head with respect to the *base of the skull*. See **ANATOMY**, vol. i. p. 731. (f)

BASILIC VEIN, in Anatomy, that large superficial vein of the arm, which passes next the internal or *ulnar condyle of the humerus*, and which gives off a large branch across the arm called the *median basilic*. (f)

BASILICA, a particular kind of public edifice. The word, according to its strict etymology, (from *βασιλευς* and *οικος*;) means a royal house. The basilica seems originally to have been a hall in which justice was administered; and as this was, in the primitive ages, the exclusive prerogative of the sovereign, it might then, with great propriety, be called the house of the king. All the ancient basilicas have been so completely destroyed, that scarcely any thing is known with certainty of their form and internal arrangement. The basilicas at Rome were spacious halls built around the forum, where the different orders of judges administered justice, and where public business of every kind was transacted. The first of these halls was built under the direction of M. Porcius Cato, the censor, in the year of the city 566. Vitruvius, the only ancient architect of whose writings we have any remains, gives the following directions for the construction of these buildings: "That merchants who resort thither on business may not be incommoded by the weather, the basilica should be built adjoining to the forum on the warmest side. Its breadth should not be less than one third, nor exceed one-half of the length, unless the nature of its situation render it necessary to depart from these rules of symmetry. The height of the columns must be equal to the breadth of the portico, which occupies a third part of the space in the centre; the upper columns should be one-fourth less than the lower. The pluteum, between the upper columns, should also be made one-fourth less than these columns, that those who walk on the floor above may not be seen by the merchants below." From this description it appears that the basilica consisted of a great nave in the middle, surrounded with one range of porticoes, and a single row of columns.

It has been erroneously supposed, that the ancient basilicas were converted, on the overthrow of paganism, into Christian churches. Buildings of a similar form, and of the same name, were indeed occupied by the early Christians for the purposes of their worship; but the details of their architecture forbid us to refer these buildings to a remoter date than the reign of Constantine, when Christianity first became the established religion of the empire. Constantine reared many of these edifices, as monuments of the triumph of his religion. One built on the site of his own palace on the Cælian Mount is ascertained to be the most ancient of these Christian basilicas. He next demolished the Circus of Nero, and the temples of Apollo and Mars, to raise on their site the magnificent basilica of St Peter of the Vatican. It consisted of five aisles from east to west, terminating at the end in another aisle from north to south, in the centre of which was a large tribunal, giving the whole the form of a cross. The aisles were enclosed by numerous columns of the richest marble; superb paintings covered the walls; mosaics of exquisite beauty adorned the tribunal; and the whole temple was illuminated by an incredible number of lamps. This magnificent edifice, respected even by the barbarous conquerors of Rome, stood uninjured for twelve centuries; till, yielding at length to the corrosive influence of time, it was pulled down by Pope Julius II., and the famous church of St Peter, the grandest specimen of the ecclesiastical basilica, and the boast of modern Rome, rose out of its ruins. As the simple grandeur of ancient architecture was lost in the clumsy magnitude of the Gothic structures, the airy elegance of these ecclesiastical basilicas, consisting of quadrilateral halls, with a single roof and flat ceiling, supported on ranges of light pillars, degenerated into the awkward cross-shape, the vaulted roof, and the massy columns of the modern cathedral. See *Encyclopedie Methodique, Arch de A. Palladio*, and *Vitruvius*.

BASILICATA, a province of the kingdom of Naples, so called from the emperor Basilicus II., and situated between the two great arms of the Appennines which embrace the gulf of Taranto. It is about 66 miles long, and 50 broad, and contains 1,284,038 English acres. It is traversed by several branches of the Appennines, and is watered by the rivers Basiento, Brandano, Salendrella, Acri, Sina, and Coscile. It is bounded on the east by the gulf of Taranto, and produces corn, wine, oil, cotton, saffron, honey, and wax. Venosa and Acerenza are the principal places of the province. Population 325,682. (w)

BASILICUS, or **BASILISCUS**, in Zoology, a subdivision of the *Lacerta*, or lizard tribe, formed into a separate genus by Laurenti and Daudin, and comprehending those lizards which have a tail compressed laterally, and a crest proceeding along the back from the tail to the neck. See **HERPETOLOGY**. (f)

BASILIDES. See **CHURCH HISTORY**.

BASILISK, a creature famous among the earlier writers of natural history for its dangerous properties. It is described by Galen, Pliny, Lucan, and several other naturalists and poets among the ancients, and by Lobo, Prosper Alpini, and Aldrovandi, among the moderns. From their accounts we gather, that the basilisk was a kind of serpent, or reptile, of a yellowish colour, having on its head several little prominences of a speckled appearance, and furnished with eight feet, and two large scales that served it for wings; that its breath was eo

pestilential as to taint the air around it, and prevent any other animal from breathing in the same atmosphere; and that even its look was so piercing and so baneful, as to cause instant death to the person on whom it fixed its terrible glance; that it inhabited the deserts of Africa, and the lakes that form the sources of the Nile, where, like the phoenix, it reigned alone in gloomy solitude. From this circumstance, some have derived its name from the Greek βασιλιζομαι, to reign; while others choose to draw the etymology from the crowned appearance of its head. Its origin was not less extraordinary and portentous than its figure or its properties. It was generated from a cock's egg, hatched by a serpent.

Such is the substance of the accounts which the credulity or invention of the above authors have handed down to posterity. We forbear to abuse the patience of our readers, with relating the many idle and puerile stories which are told of this wonderful reptile; but we may remark, that a similar instance of credulity still prevails in this country, respecting what is called the *cockatrice*. This creature, worthy to rival the basilisk in its nature and origin, is generated from the egg of an old cock, hatched, not by a serpent, but a toad; and so dreadful is justly deemed this unnatural progeny, that the building, in which such a phenomenon has taken place, must be burnt to the ground, as the only means of averting the danger impending on the master or his family. (J)

BASILUZZO, one of the Lipari islands on the north of Sicily, about two miles in circuit, and considerably elevated above the level of the sea. A small quantity of corn and pulse, which grow on its level summit, are the only nourishment for the inhabitants of two small cottages. Spallanzani is of opinion, that this and the other Lipari islands is of volcanic origin; but professor Jameson seems to think that they are composed of rocks of the newest flætz trap, or second porphyry formation. See Spallanzani, *Voyages dans les deux Siciles*, vol. ii. p. 140; and ALICUDA. (π)

BASINGSTOKE, a market town in Hampshire, pleasantly situated in an open and fertile country. The ruins of the chapel of the Holy Ghost, situated on an eminence on the north side of the town, and the newly erected market-house and town-hall, are the only objects deserving of notice. The principal manufactures of the place are shalloons and druggets; and the communication with London, by means of the Basingstoke canal to the river Wye, has increased its market for corn and malt. Number of houses 512. Population 2589, of whom 355 were returned as engaged in trade. See Warner's *Collections for the History of Hampshire*. (π)

BASKET SALT. See SALT.

BASLE, **BASIL**, or **BALE**, one of the cantons of Switzerland, situated on the banks of the Rhine, and bounded on the north by Alsace and Brisgaw; by the Frickthal, or the territory of the forest-towns, and the canton of Soleure, on the east; on the south by the canton of Soleure; and on the west by the bishopric of Basle. It extends about 20 miles in length from north to south, and about 18 in its greatest breadth from east to west.

The climate of this canton is temperate and salubrious, and the country is delightful. Though mountainous, it has many vallies and plains, extremely fertile and well cultivated, while the varied aspect of the mountains themselves render the scenery at once beautiful

and grand. Many of the smaller hills are covered with vineyards, or clothed to the summits with luxuriant herbage; beyond which its mountains, forming part of the chain of Jura, tower in Alpine majesty, and seem to form an insuperable barrier around the country. The Rhine, too, which flows through this canton, greatly heightens the sublimity of the scenery. In no part of its course does it fill an ampler channel, or roll its mighty stream with such an impetuous rapidity. Few places in Europe are blessed with a greater profusion of comforts, and even of delicacies, than the canton of Basle. Plentiful crops of grain, fruits, and grapes, are the productions of its genial soil; its forests harbour great variety of game; and the noble river which enriches its fields, teems with different species of excellent fish.

The bounty of nature is here seconded by the industry of the inhabitants. Agriculture, manufactures, and their attendant arts, fostered by a discerning government, are pursued in this country with the ardour naturally inspired by the certainty of a rich return. The principal branches of manufactures, are ribbons, of which, so far back as the year 1777, there were no fewer than twenty factories in the capital, which distribute annually upwards of 300,000 florins, as wages to the workmen; silken stuffs; figured cottons; bonnets; gloves; paper-making; bleaching, and dyeing. These manufactures, supported by agriculture, in their turn contribute essentially to its improvement, by increasing both the consumption, and the means of enriching the soil.

The population of the canton is estimated at 40,000 persons, and its extent is about 160 square miles.

Previous to its subjugation by the French, the government of Basle was aristodemocratical. The supreme power was vested in two assemblies, called the *Great and Little Council*. The great council was composed of 216 members, taken from the 18 tribes of the large and small town; the little council consisted of 60 members, 4 being elected from each of the 15 tribes of the great town. To these we must add two burgomasters, and two grand tribunes, who were the four chiefs of the canton. The supreme council, composed of these 280 persons, decided on all the great political and economical interests of the state; exercised legislative power; and disposed of all the principal offices, which could be held by none but burghers.

Once a year the people assembled, to receive publicly, an oath, made by the magistrates, that they would maintain the laws in their integrity, and preserve the public rights and immunities inviolate. A reciprocal oath of allegiance to the magistrates was taken by the people in their respective tribes. Nowhere was the conduct of magistrates more strictly scrutinised, or more freely censured than at Basle. In the exercise of their right of scrutiny, the people, always ready to mistake turbulence for freedom, have frequently become tumultuous and disorderly; yet it cannot be denied, that the effects of this privilege, were, in general, salutary. While it deterred the magistrates from every species of injustice, it enlightened the other members of the community with regard to those laws of which they were the vigilant guardians, and fostered in them a spirit of independence which was the best security for the integrity of their constitution.

The little council was divided into two parts, over each of which a burgomaster presided, together with

a grand tribune, who succeeded the burgomaster, in case of his death. Each division governed for a year. This council had the right of judging petty crimes, of deciding causes of appeal from the citizens, and disposing of benefices in the church, and the inferior offices in the state. It was confirmed annually by the great council, each member of which was likewise confirmed by the other members of the two councils, who belonged to the same tribe with himself.

The canton is divided into seven bailliages: of the bailiffs, whose jurisdiction generally continues eight years, four are chosen from the little council, and two others indifferently from the great council, or from the company of burghers.

The mode of electing magistrates and members of the councils was sufficiently singular. Formerly the choice used to be made by a plurality of voices; but as the intrigues and influence of the more opulent and powerful gave them the ascendancy in every election, it became necessary to adopt some other expedient. Three citizens were therefore selected, one of whom was chosen by lot to the vacant office. This was called the *ternaire*. Even this method, however, not being sufficient to counterbalance the influence of the wealthy, six candidates were selected instead of three. Their names enclosed in silver eggs, were placed in one bag; and six cards, on one of which was inscribed the vacant employment, were put into another. The reigning burgomaster and the great tribune drew at once from these two bags; and he was the successful competitor whose name was brought out at the same time with the ticket on which the destined office was inscribed. This mode of election was called the *senaire*.

The same republican jealousy gave rise to a regulation which rendered it impossible for a father and son, a father-in-law and son-in-law, or two brothers, to be admitted at the same time either into the little council, or into the number of members of the great council chosen from the same tribe. While a nobleman, who was unwilling to resign his title of nobility, could not be elected a member of the supreme council, that honour was open to the meanest of the community; for the vacancies in the two councils were supplied from all ranks of citizens, the members of the university alone excepted.

It is natural to suppose that many inconveniences must have resulted from the absurd practice of supplying the vacant posts in the government by lot. Candidates, whose talents and integrity would have secured the deliberate preference of their countrymen, might constantly fail to obtain the successful ticket, which fortune might bestow on one altogether unqualified for the employment to which he aspired. Notwithstanding these inconveniences, however, the government was in general well conducted; and very few instances occurred of the abuse of civil justice, or of innocence being sacrificed to the powerful or the opulent.

The same mode of election was employed, still more absurdly, in supplying the vacant chairs in the university; as if genius and knowledge were equally shared among the literati of Basle, and selection were a matter of perfect indifference. The professors, however, were extremely accommodating to one another; for as it frequently happened that the successful candidates were but little acquainted with the sciences which they were appointed to teach, they merely exchanged chairs, and

thus matters were set to rights. In this are the *ternaire* was employed, and the three candidates were nominated from those who had taken the degree of doctor.

With regard to the military constitution of Basle, the town and its suburbs are divided into six companies of burghers. The country furnishes two regiments of militia, each consisting of nine companies of fusileers, a company of grenadiers, and one of dragoons.

The Basilians are Protestants, and the clergy form in the capital a *conventus*, and three chapters in the country. Over all these, the first pastor of the cathedral presides. In all the reformed churches of Switzerland, the ministers are entitled to sit with the secular judges in the consistory, which tribunal can decide in cases of fornication and adultery, as well as on causes of matrimony or divorce.

The inhabitants of this canton are remarkable for their gravity of deportment, and would consider any indulgence in playful levity, as very derogatory from their dignity. In general they are extremely attached to their own country, which they seem to regard as the only abode of terrestrial happiness. They were, indeed, one of the happiest nations on earth, till the emissaries of France, deluding them with the visionary prospects of absolute freedom and equality, involved them in all the miseries of civil revolution and foreign subjugation. Basle was the first canton which separated from the Helvetic confederacy, and adopted the new constitution fabricated for Switzerland by its French oppressors. The progress of the revolution was here almost instantaneous. The peasants, always jealous of the monopolies of privileges vested in the burghers, and now urged on by the artful intrigues of the French, rose in different districts, demolished the castles of the bailiffs, and loudly demanded emancipation and independence. The magistrates, overawed by the enemy's army, which had already overrun the bishopric of Basle, and now threatened their capital, were obliged to submit without a struggle. On the 24th of January 1798, the tree of liberty was planted on the walls of the city; and on the 5th of February, the magistrates resigned their authority, and sixty delegates appointed by the people, were invested with temporary power, till the new constitution should be properly organized. With the addition of the lower part of the Frickthal to Seckingen, Basle forms one of the departments into which Switzerland was divided by the constitution of the 29th of May 1801, with the right of sending three representatives to the diet. See *Dictionnaire de la Suisse*, and Coxce's *Travels in Switzerland*, vol. i. p. 66. of the introduction, and *Letters* 15 and 16. (u)

BASLE, or BASIL, the capital of the above canton, is beautifully situated on the banks of the Rhine, about 60 miles south of Strasburg, and 120 north-east of Geneva. The river, which is here in its greatest beauty, broad, deep, and rapid, divides the city into two parts, called the large and small town; which are joined by a noble bridge of 14 arches, and about 600 feet in length. Each of these divisions is surrounded with walls and a ditch. Without the compass of the large town there are fine extensive suburbs, which form so many distinct quarters, and are all enclosed by a regular rampart. Basle is the largest, and was once the most populous town in Switzerland. It is capable of containing upwards of 100,000 inhabitants, though its present population does not exceed 14,000. To account for this de-

crease, we may observe, that the natives of Basle, like the rest of the Swiss, have always been fond of emigration, and that here, as in all great cities, the number of births is inferior to that of burials. It is evident, therefore, that if the loss of numbers, thus produced, be not supplied by a regular accession of new inhabitants, the population must be rapidly diminished. Now the Basilians are so proud and so jealous of their rights and privileges as burghers, that they very seldom deign to confer them on strangers, who, thus deprived of the power of engaging in commerce, or practising any trade in the capital, have no inducement to resort thither to supply the vacancies made in the population, by the emigration or death of the native citizens. A more enlightened and liberal policy might have rendered this city extremely populous and flourishing; for it is most favourably situated for commerce, and enjoys besides, several internal advantages peculiar to itself. No place can boast of a greater number of fountains, some of which have even their source within the town; besides the Birs, a stream which falls into the Rhine, a little above the city, supplies it by means of a canal with water, particularly well adapted to various purposes of trade.

This city is adorned with many noble streets and spacious squares. Its houses are in general built of stone, in a neat and elegant taste. Except some splendid mansions, in which a few rich manufacturers display their wealth, there are no buildings in Basle, whose magnificence can offend the republican spirit of its inhabitants; but in every house there appears that air of neatness and of comfort, which is the truest enjoyment, and the natural privilege of easy and independent circumstances. The cathedral is a superb Gothic structure, but is much disfigured by the rose-coloured paint with which it is bedaubed. It contains the monuments of many illustrious persons, and is particularly consecrated by that of the great Erasmus, who made this town his principal residence, and published here many of his valuable works. The terrace of this cathedral, which serves as a public promenade, commands a very rich and extensive view; but on another side there is a covered gallery, full of tombs and monuments, the unseemly appearance of which is as indecorous for the dead, as its noisome exhalations are pernicious to the living. Besides the cathedral, this town contains six parochial churches, and seven convents, which were secularised by the Reformation.

The public library is more remarkable for the rare and valuable editions of the books which it contains, than for the number of its volumes: it is enriched with numerous manuscripts, the most curious of which are the letters of the first reformers, and of other learned men in the 15th, 16th, and 17th centuries; and an account of the proceedings at the council of Basle. Here, too, are preserved with great veneration, the hanger and seal of Erasmus, some of his letters, and his last testament, in his own handwriting. There is a suite of apartments connected with the library, which contain a cabinet of petrifications, some ancient medals and gems, a few antiquities found at Augst, a large collection of prints, and some admirable drawings and paintings, consisting chiefly of originals by Holbein, who was a native of Basle, and the favourite painter of Henry VIII. to whom he was introduced by Erasmus. In these paintings, which are in high preservation, the progress of Holbein may be traced, from the earliest efforts of

his pencil, till he attained that perfection in the art for which he has been so generally admired. Some pictures are preserved which he painted before he had reached his 16th year; and one, particularly curious, which he drew upon a sign for a writing-master. The most esteemed of his productions is an altar-piece, in eight compartments, which represents the passion of our Saviour: a performance, which, for brilliancy of colouring, cannot be exceeded. The Dance of Death on the walls of an ancient convent of Dominicans, pointed out to strangers as a production of Holbein's, has been proved, from incontestible authority, to have been painted before he was born.

The hall still remains, in which were conducted the deliberations of the famous council of Basle, which, after sitting for many years, came to the resolution of deposing the pope; and published many edicts for the reformation of the church. A picture is still to be seen on the staircase of the zeal of the council-house, supposed to have been suggested by these pious fathers, in which the devil is represented as driving the pope and several church dignitaries before him into hell. Basle is the seat of an university, which once ranked among the most eminent seminaries of learning in Europe. It was founded in the year 1460, by Pope Pius II. and its fame will be perpetuated in literary history by the illustrious names of Oecolampadius, Amerbach, the three Bauhins, Grynæus, Buxtorf, Wetstein, Iselin, the Bernoullis, and Euler. All travellers have been struck by a singularity in the regulation of the clocks of Basle, which were always exactly an hour faster than the real time of the day. The origin of this peculiarity was unknown even to the natives; yet they seemed to think, that it in some manner reflected upon them a national honour, for every proposal to regulate the clocks by a sun-dial was opposed with the utmost violence. The clocks, however, like the people, now move under the direction of other masters, and are no longer allowed to outstrip the sun. The inhabitants of Basle claim the honour of having invented the manufacture of paper in 1417, and of having discovered the art of printing in 1418. N. Lat. 7° 35', E. Long. 7° 29' 30". See Coxe's *Switzerland, ubi supra. Dictionnaire de la Suisse. Moore's View of Society in France. Germany, and Switzerland*, vol. i. p. 178. (u)

BASLE, or BASIL, Bishopric of, a province of Germany, in the circle of the Upper Rhine. This province, which forms part of the ancient territory of the Rauraci, is of great extent; beginning at the lake of Biemme, it crosses Mount Jura, and stretches almost to the very gates of the town of Basle. It is bounded on the north by Sundgaw Proper; on the west by Franche Comté; and on the east and south by the Swiss cantons of Basle, Berne, and Solcure. It lies partly in Germany, and partly in Switzerland: to the south of Pierre Pertuis it belongs to the latter country; to the north of the same boundary it belongs to the former. While it remained a separate state, the bishop was a prince of the German empire, and did homage to the emperor for his German territories. He was connected, at the same time, by an alliance with the seven Catholic cantons of Switzerland, but was never included in the Helvetic Confederacy. He was elected by the chapter of 18 canons, resident at Arlesheim, and confirmed by the pope. His government was a limited sovereignty; he was obliged on all occasions to consult his chapter; and his prerogative was extremely confined by the immuni-

ties of his subjects. The whole province is now annexed to the dominions of France, and forms the department of Mont Terrible. The inhabitants are Protestants and Roman Catholics. The Protestants reside chiefly in the valley of Munster, and in the district to the south of Pierre Pertuis, and are in number about 15,000. The Roman Catholics are estimated at 35,000. This province is remarkable for its romantic scenery, and for the variety of its fossus and petrefactions. The only towns of note which it contains, are Porentru, formerly the episcopal residence, and Delmont. See Coxe's *Travels in Switzerland*, lett. 18.; *Dictionnaire de la Suisse*; and *Encyc. Methodique*. (μ)

BASRAH. See BASSORAH.

BASS, a great rock in the Firth of Forth, about three miles from the shore, directly opposite to the promontory upon which the ancient fortress of Tantallon is situated. It is nearly round, not above the sixth of a mile in diameter, and about four hundred feet above the level of the sea. Towards the south, that is, opposite to the land, it declines with shelving rocks to the water, where it affords the only landing place. Yet here it is accessible only in calm weather, and even then not without danger, to those who are unaccustomed to make good their landing, by catching the rise of the boat upon the top of a wave. Towards the west, north, and east, it rises perpendicularly out of the sea, near two hundred feet high; and in some places, this lofty precipice projects at the top, which, to those who sail round it, has a frightful appearance. In other places this vast rock is excavated to a great depth by the waves. Upon the south side, where the isle has a gradual descent, the sea is shallow; but on the west, north, and east, where it is perpendicular, the sea is from two to three hundred feet deep, close by the side of the rock. As far as we can judge from hand specimens, this isle appears to be principally composed of clinkstone, and therefore belongs to the newest flætz trap formation.

The most remarkable land plant which this isle affords, is the beautiful *lavatera arborea* of Linnæus. Of sea plants it contains but few species, as the *lucus saccharinus*, *fucus loreus*, &c.

Very few zoophytes occur. The most abundant, and in every respect the most interesting bird of this isle, is the pelicanus bassanus of Linnæus, the solan goose. They arrive at the Bass in the month of March, and after they have bred go away in September. Yet generally some few stay about the island the whole winter, which are judged to be the old ones, that are not able for the distant flight undertaken by the others. They neither arrive or depart all at one time. Before their arrival a few of their number come to the Bass, which are supposed to be dispatched as scouts; and in some days thereafter, the main body arrives in several successive divisions. Dr Walker gives the following statement of the rent and produce of the Bass.

Rent of the Bass.

Rent to Sir Hugh Dalrymple, Baronet, the proprietor,	
840 merks, or	L.46 13 4
To the climber 100 merks, or	5 11 1 ³ / ₄
To seven men employed in catching the fowls, 16l. Scots each, or	9 6 8
To the carrier 36 times to Edinburgh, 28 stone each time	5 12 0
Total	L.65 3 1³/₄

Produce of the Bass.

They take the solan goose thirty-six times in the season, and at a medium thirty-six every time; which, at 1s. 8d. sterling each, is	L.118 9 0
Sheeps grass	5 0 0
Ten Scots gallons of oil, drawn from the fat of the fowls, at 8d. sterling each pint	2 13 4
Ten stone weight of leathers, at 10s. per stone	5 0 0
	<hr/>
	L.130 13 5

BASS STRAITS, a channel in the Australasian regions, situated in 40° of south latitude, and 147° 148° east longitude, which separates New Holland from Van Dieman's Land. We do not know that the precise extent to be included in this channel is definitively fixed: the navigators of the French expedition who explored it in 1801, say it is about 50 leagues in length from east to west, and the same in breadth from north to south. All the earlier navigators supposed New Holland a vast continent including Van Dieman's Land, the southernmost point of which was considered the extremity of New Holland; but circumstances induced several of those who more lately traversed the Australasian seas, to conjecture that there might be some strait or channel dividing them. No one, however, could penetrate further than into what they called deep bays and inlets. At length, ten years after the establishment of the English colony of Botany Bay, Mr Bass, the surgeon of a man of war, disliking the idleness which particular occurrences exposed him to, made an excursion in an open boat, which fortified him in the belief of an open passage, separating New Holland and Van Dieman's Land into two great islands. A subsequent voyage proved the fact, and the strait received his name.

Bass Straits have been surveyed by Captain Flinders along with Mr Bass, by the officers of the French expedition, and by Captain Grant of the British Navy. The discovery of them has been judged of material consequence in shortening the voyage from Europe to India. Many vessels have now passed through them, but from the rocks and islands with which they abound, experienced seamen affirm that it is a voyage of danger.

Commercial enterprise has given birth to active operations in fisheries established in different parts of the straits. Parties are carried thither in small colonial vessels from Port Jackson, and established in gangs of ten or twelve, to collect seal skins and the oil of the sea elephant, for animals of the *Phoca* tribe are extremely plentiful in this channel. These speculations were for some time confined to the settlers exclusively; but the Americans began to avail themselves of the same advantages, and the number of adventurers increased so rapidly, that in a few years after its commencement the fishery was rather on the decline. The British government, however, resolving to encourage the enterprise of its own subjects, attempted to establish a colony at Port Philip, on the north shore of the straits. The different gangs engaged in the fishery previously shifted their abode from place to place as the objects of pursuit became scarce, and the collections they made were sent to Port Jackson. Port Philip, it was thought, would be a secure place of rendezvous, where the produce of the fishery might be deposited until ready for ex-

portation; and it would besides prevent any rival nation from establishing a settlement on the coast, and proving troublesome neighbours to Port Jackson. Nevertheless this attempt proved abortive, and the settlement was removed. See COLLINS' *Account of Botany Bay*, FLINDER'S *Voyage*, TUCKEY'S *Voyage*, GRANT'S *Voyage in the Lady Nelson*, PERON *Voyage aux Terres Australes*. Also AUSTRALASIA, and PRESERVATION ISLAND. (c)

BASSANO, a town of Italy in the Trevisano, situated on the river Brenta. It is nearly 5 miles in circumference, and contains 30 churches, 2 monasteries, and 3 hospitals. One of its gates was built by Palladio. A large printing establishment, and some silk and woollen manufactures, are the only objects deserving of notice. Population 11,300. East Long. $11^{\circ} 43'$, North Lat. $45^{\circ} 46'$. (j)

BASSE DES FREGATES FRANCOISE, a dangerous rock in the North Pacific Ocean, about 100 yards long, and 50 high, situated on the north-west extremity of a reef of rocks, stretching about 12 miles to the south-east. West Long. $165^{\circ} 50'$, North Lat. $23^{\circ} 45'$. A more full account of this rock, with its surrounding shoals, will be found in La Peyrouse's *Voyages*. (j)

BASSEEN, a fortified town of Hindostan, on the western coast of the peninsula, situated about 20 miles north of Bombay, in an island separated from the continent by a small rivulet. In the year 1670, it was a considerable city, with two colleges, six churches, and four convents. East Long. $72^{\circ} 40'$, North Lat. $19^{\circ} 20'$. (j)

BASSET, the name of a game at cards. See De Moivre's *Doctrine of Chances*, p. 69.

BASSIA, a genus of plants of the class Dodecandria, and order Monogynia. See BOTANY. (w)

BASSO RELIEVO, that branch of sculpture which represents figures in such a manner that no part of them is detached from the back ground; distinguished from alto relievo, which has the grosser parts of the figure attached to the back ground, while the minuter parts rise completely free from its surface. The term is of modern date, but the art itself is of nearly as remote antiquity as the hieroglyphic mode of writing, from which indeed it derives its origin. In Greece, where sculpture, in all its branches, reached the highest perfection, basso relievo was called *ανυψωπιη*, *carved work*; and the alto relievo was distinguished by the name of *ροσσεινισ*, *rounded*; appellations which contain in themselves an accurate definition of these different species of the art. For a more detailed description of basso relievo, see SCULPTURE. (u)

BASSORA, BUSSORA, or BASRAH, a city of Arabian Irak, in the Pachalik of Bagdad, is situated upon an arm of the Schatt el Arab, or river of the Arabs, about midway between the gulf of Persia and the junction of the Euphrates and Tigris. It was built by the Caliph Omar, in the 16th year of the Hegira, to command the trade between India and the eastern empire, and to restore the communication by the Persian gulf, which had been cut off by the conquests of his predecessor. Planted in the midst of a delightful country, and surrounded by fertile pastures and luxuriant orchards, a little colony of 800 Moslems rapidly increased in numbers and in opulence. Under the first caliphs its jurisdiction extended over the southern provinces of Persia; and, from the influence of its situation as a port of trade, Bassora soon rose one of the first commercial cities of

Asia. Its harbours, which afforded a commodious station for ships of the greatest burden, was filled with vessels from every nation. The riches of Europe and India were accumulated at Bassora, and its merchants were considered as the most opulent and industrious in the East. Its importance, however, as an emporium of trade, has of late rapidly declined. In comparison with its former prosperity, commerce has lost its vigour and activity; industry and the arts are almost extinguished; and the town itself is fast hastening into insignificance. Houses wretchedly built, and streets covered with filth, surrounded with a sorry mud wall, present to us the humiliating picture of the once flourishing city of Bassora. The bazars, or market place, however, are extensive and well supplied, particularly with every description of fruit, such as apples, grapes, peaches, nectarines, pomegranates, &c. and the cabbages and other vegetables are equal to any in Europe. Such is the honesty of the natives, or rather such is the rigour with which theft is punished by the Turkish government, that these articles lie exposed all night in the open market, without any other protection than a mat thrown over them to screen them from the weather. The pale complexions, and the weak and sickly constitutions of its inhabitants, betray the unhealthiness of the climate, which is rendered almost uninhabitable by the annual overflowing of the river, which forms, in the vicinity of the city, marshes and ponds, where the stagnant water putrifies during summer, and poisons the atmosphere with its noxious exhalations. Mounds of earth are raised by the natives to prevent these inundations, but they are frequently broken down by the violence of the water, which, spreading far into the plain, deposits there the seeds of disease and of death. This circumstance, joined to the terror which the Wahabees have inspired by their frequent incursions into the country, and the numerous pirates which infest the Persian gulf, has tended considerably to depopulate Bassora, and to bring it to its present degradation. What remains of the commerce of this city is chiefly carried on by the English and Arabs; and, notwithstanding these untoward circumstances, it is still a general staple for various kinds of merchandise. Coffee from Mocha; pearls from the islands of Bahrein; plain and embroidered cloths, silk stuffs, spiceries, and drugs, from India; dried fruits, tobacco, carpets, and perfumes, from Persia,—are here exchanged for gold, silver, copper, dates, and various European commodities, such as small ironware, satins, woollen cloths, &c. which come through Syria by way of Bagdad. Horses, also, form here a considerable article of commerce. They are said to be the most beautiful and strongest in the world, and capable of performing most incredible journies. They are exported in great numbers by the English consul, who employs some ships for this purpose. The merchandise annually brought to Bassora was valued by the Abbé Raynal at 525,000*l.*; of which the English furnished 175,000*l.*, the Dutch 87,000*l.*, and the Moors, Banians, Armenians, and Arabs, the remainder. But the revenues of this city, which were formerly very considerable, are now scarcely sufficient for its defence.

Bassora continued under the authority of the Saracens till about the middle of the 17th century, when it was taken by the Turks. It then yielded to the Persians, after a siege of ten months, but was evacuated by them upon the death of Kerim Khan. From that time it has

constituted a part of the Ottoman empire, and is governed by a lieutenant, who exercises his authority in the name of the pacha of Bagdad. Twelve armed galiots are constantly kept here for the protection of the merchant vessels which enter the Persian gulf; but they seldom venture out to sea, as they are too old and crazy to encounter the least bad weather; and the Arab tribes of *Zibes* and *Muntfiks* receive an annual subsidy of 100,000 piastres for the defence of the city. The Wahabees have frequently attempted to get possession of Bassora, but have as often been repulsed. It cannot, however, be expected that it will long withstand the fury of these sectaries, who have already subdued, or converted, most of the neighbouring tribes. The population of Bassora is composed of a mixture of Christians, Jews, Persians, Indians, and Sabeans, but chiefly of Arabs, and amounts to about 40,000 souls. Many of the Persians in Bassora are persons of good family, who have been driven from their country by the various revolutions with which it has been agitated. E. Long. 46°, N. Lat. 30° 32'. BASTARDY. See **ILLEGITIMACY**.

BASTILE. This name was given to the chief state prison of France, prior to the revolution in 1792. It is derived from *bastir*, to build, originally spelt *batir*, and is of the same root with the term *bastion*. There were many places of strength in different parts of France which were used as state prisons, besides the edifice called, by way of distinction, The Bastile. Thus, according to Linguet, (*Mem. sur la Bastille*) there were "Pierre en Cise," at Lyons, the Isles of St Margaret in Provence, Le Mont St Michael in Normandy, the Chateau du Taureau in Brittany, the Castle of Ham in Picardy, that of Saumur in Anjou, and others, amounting, in all, to nearly a twentieth part of the fortified places in France. Each of these had its governor, its etat major, its inferior officers, and its prisoners.

The Bastile, properly so called, was situated at the gates of Paris, near the road to St Anthony. It was built in the reign of Charles V., A. D. 1570, by Hugh d'Aubriot, mayor of the city. According to the original plan, it consisted of nothing more than two round towers on opposite sides of the street, joined together by a cross wall of great strength, having in the middle an opening for the gate. This opening was afterwards shut up, when the course of the road leading into the city was changed. Charles VI. built several other towers, forming, by means of intervening walls, two complete courts, which may be regarded as the body of the edifice: the whole was then inclosed within a ditch, and secured by a counterscarp, or facing in masonry, nearly 36 feet from the bottom. In the courts alluded to, the walls were of an extraordinary thickness, and on the inside they extended to the height of 80 feet above the level of the pavement. The other parts of the building were added occasionally under different monarchs. It was in the towers that the prisoners were usually confined. The structure of all these was nearly uniform; so that, from a description of one, the reader may be able to form an idea of the rest. Each tower consisted of four stories, besides the dungeon. This last was arched,

paved, and lined with stone; the top, or ceiling, being almost on a level with the court, and the floor raised considerably above the bottom of the ditch. In some of the dungeons there was a slit in the wall for the admission of light, but in others there was none. There was no stove or fire-place in any of them. It is said that these abodes of darkness and misery were intended for the punishment of such as endeavoured to escape from their confinement. It may have been so; but, after making every allowance for exaggeration, it is not to be denied, that the unhappy victims of tyranny, who, for whatever reason, were doomed to occupy them, were not unfrequently the subjects of the most studied and persevering cruelty. In these dungeons the princes of Armagnac were immured by the orders of Louis XI. One of them, sinking under the weight of wretchedness and despair, became disordered in his mind during his confinement; and the other, upon a change in the government, recovered his liberty, and afterwards published an account of his sufferings. Above the dungeons rose successively four apartments, each occupying a single story. The uppermost, named *la cabotte*, was somewhat smaller than the others. The intermediate ones were irregular polygons, nearly 18 feet across the floor, and of the same height. From the dungeon ran a winding staircase towards the apartments above. The walls were 12 feet thick at the highest part of the tower, and increased in diameter as you approached the bottom. On the parapet some pieces of ordnance were usually mounted.

With regard to the individual apartments, the same massy strength and gloomy grandeur which characterised the rest of the building appeared in them also. The doors were of oak, and double, each three inches in thickness. None of the rooms had more than one window, which, in every instance, was secured by an iron grate of prodigious strength on the outside, and by another of similar dimensions fastened in the centre of the wall. The frame, containing the glass, moved upon hinges, and opened inwards, after the manner of a door. In some instances, the embrasure, or under part of the window-case, reached the level of the floor, but in others it was necessary to ascend to it by a flight of steps. In the lower stories the windows were built up nearly the half of their length with stone, lest the prisoner should be discovered by any one from without. The chimney was likewise secured by iron grates, crossing the vent at proper distances. The floors were laid with stone, or tiles. Most of the apartments had the same kind of furniture, both as to the number of articles and their quality. It usually consisted of a bed, a table, and a chair, a bason and ewer, a large earthen pitcher for holding water, a candlestick, generally of brass, a night-stool, a pot de chambre, a broom, and a tinder-box, with a supply of matches. Persons of distinction, however, were often better accommodated, having rooms according to their dignity, and being allowed, in particular circumstances, the convenience of their own furniture. Each apartment was numbered; and as every tower had its name, it was not at any time necessary to say who the prisoners were when orders were given with respect to them, or when they happened to be the subjects of conversation: but only to mention them in the language of the place, as No. 1. *Du Tresor*: No. 2. *De la Contè*; No. 3. *Du Coin*, &c.

The officers who had the direction and charge of the Bastile were the following: The governor; the lieute-

nant du roi; a major with two adjutants; a surgeon and his assistant; a chaplain; four turnkeys; together with a company of invalids under their usual officers forming the garrison. All these had their apartments within the walls of the castle. Besides these, there were the physician; two priests assistants of the chaplain, enjoying each a salary of 400 livres; a keeper of the registers; a clerk; a superintendant of the works, and an engineer. The attendance of these was occasional, and they usually lived in the city. To the governor was entrusted the whole internal management of the Bastille: he administered the oath of allegiance to the inferior officers: he received from the king a certain allowance for the support of each prisoner according to his rank; and the cooks and other persons belonging to the kitchen were all engaged and paid in his name. The maintenance of a prince of the blood was estimated at fifty livres daily; that of a *marechal de France* at thirty-six; that of a lieutenant-general at twenty-four; that of a member of the French parliament at fifteen; that of a judge, priest, or person holding any situation of importance under the crown, at ten; and that of a respectable citizen at five. In each of these instances, however, the estimate is to be considered exclusively of the charges for fire and candles, as well as the expense of washing. It belonged to the major to examine the prisoners immediately after their arrival, or, according to the orders received, in presence of the *lieutenant du roi*. The officer last mentioned had also the charge of the keys, which were delivered to him every night as soon as the bridge was drawn up. Certain individuals of the staff made their rounds daily, and gave an account of what they had seen and heard at their visits, either to the governor in person, or in his absence to some one appointed by him. But the governor and all the officers mentioned above, were wholly passive; they did nothing without orders from the lieutenant of police, and he himself indeed acted only as deputy to the minister of Paris, in whose department the Bastille was situated. It was by that minister, or by one of the secretaries of state, that the *lettres de cachet* were countersigned; those awful intimations of despotism, by which thousands were deprived of their liberty and their reason, and not unfrequently of their lives. These letters were sometimes addressed to the individual, whom the caprice of the monarch or of his favourite had doomed to confinement, sometimes to the governor of the Bastille exclusively, but commonly to both. The following is an instance of a *lettre de cachet*, inscribed "A mon cousin le Prince de Monaco, brigadier en mon enfance," by Louis XV.

" Mon Cousin,

" Etant peu satisfait de votre conduite, je vous fais cette lettre, pour vous dire; que mon intention est d'aussitôt qu'elle vous aura été remise, vous ayez à vous rendre en mon chateau de la Bastille pour y rester, jusqu'à nouvel ordre de moi. Sur ce je prie Dieu qu'il vous ait, mon cousin, en sa sainte garde. Ecrit à Versailles, le 25 June 1748.

Signé LOUIS.
VOIER D'ARGENSON."

*Le Sieur Prince
de Monaco.*

When tyranny was at its height, the *lettres de cachet* were subscribed by the king and given to the minister,

with spaces left for the names of those who were so unhappy as to incur the displeasure of either: And the minister, thus unwisely put in possession of absolute authority, became, in many instances, the terror and the aversion of all who were sufficiently eminent to attract his notice. In allusion to this absolute authority, it was sarcastically said by one of the wits of France, "you must hold the *pot de chambre* to the minister when he is in office, but you may pour its contents on his head when he goes out."

The registers of the Bastille are three in number. 1. A book containing the names of the prisoners, the dates of their arrival and dismissal, the number of the apartment which each of them occupied, with remarks on their circumstance and behaviour. 2. A book of inventories, or lists of the articles found upon searching the prisoners as they arrived: the name of each prisoner was likewise set down in this book, opposite the catalogue of the articles belonging to him. 3. A discharge-book: This contained the receipts granted by the prisoners after the period of confinement had elapsed, when their effects were restored to them: It contained also the subscription of each prisoner, by which he bound himself under the obligation of an oath, to maintain an inviolable secrecy with respect to all that he had seen or heard in the Bastille.

The manner of arresting those whose incarceration was decreed varied, according to circumstances, but their treatment after their arrival had, in most instances, a great similarity: "La Bastille," says Linguet, "comme la mort, égalise tous ceux qu'elle engloutit." A short examination before the lieutenant du roi being over, the prisoner was commanded to give up his money, watch, and jewels; and the reason was assigned, lest he should corrupt the turnkeys, or inferior servants of the place. He was next ordered to part with his scissors and pen-knife; and here, too, the reason was given with unfeeling plainness, lest he should either cut his own throat, or assassinate those whose business it was to visit and inspect him. At this ceremony, the officers who were present, utterly regardless of the terror and apprehension often appearing in every look and motion of the prisoner, commonly indulged themselves in a brutal pleasantry, as the different articles were produced. It was then enquired what room was empty; and on receiving a proper answer, the wretched individual was conducted to his apartment. Here he sometimes remained for a long time, even for several months, before he was allowed to be shaved. This indulgence was never granted till the prisoner had been examined a second time, or till all the information which was wished for had been obtained;* and in no instance could it be granted, without permission in writing from the minister of Paris, through the medium of his deputy the lieutenant of the police. The operation was performed twice a week by the surgeon of the house; always, however, in presence of a turnkey, who had strict orders to prevent the captive from touching the razors: The surgeon likewise pared the nails of the prisoner, under similar precautions. As the governor supplied the prisoners with clothes, furniture, and faggots, out of an allowance made to him by the king for that purpose, the provision of these articles was often exceedingly scanty. Hence the wretches intrusted to his care were subjected without remedy to all the severities and changes of the cli-

* From the register of prisoners, it appears that a German called Veillard underwent no fewer than 89 examinations.

mate; to the intolerable cold of large apartments, with high ceilings, in winter, and to the heats of summer in rooms not capable of ventilation; a grievance rendered yet more distressing by the steams issuing from the water that putrified in the ditch. When upon a certain occasion a prisoner made application to the governor for more comfortable clothing, or leave to purchase it with his own money, the answer of that inhuman monster was, "Il faut ne pas se mettre dans le cas d'être à la Bastille, ou savoir souffrir quand on y est." At this reply the very *Porte-cléfs* were obliged to turn aside their heads.

It has been doubted whether the accounts given by authors of the iron-cages and instruments of torture used in the Bastille were founded in fact. After some enquiry, it appears to us, that though these accounts have been exaggerated, the modes of punishment referred to, were unquestionably practised, not perhaps in the reign of Louis XVI., but certainly in those of former monarchs. The count de Boulainvilliers relates, that he saw at the Chateau Duplessis, an iron cage in which the Cardinal de la Balue, first minister to Louis XI. had been confined. Louis XII. while Duke of Orleans, experienced a similar fortune with the Cardinal. A wooden cage, 9 feet long, 6 broad, and 8 high, was to be seen previous to the revolution at St Michael in Normandy. In this cage, the editor of a newspaper published at Leyden, who had written a satire on Louis XIV. was shut up, and died after a confinement of many years. It was placed in the centre of a room every way resembling the apartments of the Bastille; and from the great strength of the walls rendering an escape nearly impossible, it must have been designed not for security, but for punishment. Some of the bars were marked with landscapes and figures of different kinds, which the miserable captive had imprinted on it with his nails. La Porte, premier Valet de Chambre to Louis XIV. when enumerating the various means employed by the officers of the Bastille to force from him the secrets of the queen, with which they supposed he was entrusted, distinctly states, that an order was produced by the commissary acting under the lieutenant of the police, for putting him to torture in case of obstinacy, and that he was conducted to a room where the different instruments were shown him, and their application pointed out. Finally, there is good reason to believe, that in the reign of Louis XI. not a few perished in the dungeons of the Bastille, by means of poison secretly introduced into their food.

In later times, however, the torture of the mind appears to have been studied by the agents of despotism rather than that of the body. No sooner had a prisoner, for some reason or for none, entered the Bastille, than he passed at once into a state of utter exclusion from the rest of mankind. If his friends enquired after him, it was denied, even with oaths and imprecations, that he was in confinement. And the governor has been known to express his astonishment, that they should suppose him to be in the Bastille. The only persons who visited the prisoners were the turnkeys and officers of the house. On these occasions the most insidious questions were put to them, and their answers, carefully remembered, were afterwards written down. No one was allowed to approach them in whom they could confide, or from whom they could ask advice. And if, in particular circumstances, a companion was allowed to certain prisoners, more guarded and cautious in their answers than

others, this companion having drawn from them the requisite intelligence, soon appeared to be a spy placed there by the orders of the governor. The mind of the captive was kept in a state of fixed uncertainty. He was uncertain even for what cause he was detained. He was uncertain whether his wife and family yet existed, whether they breathed the vital air in the enjoyment of their liberty, or whether they were shut up in the next apartment of the castle, doomed to the same misery which he endured. Of his own destiny he was equally uncertain. He might be confined to his dungeon for many years, still cherishing the hope, and meditating on the blessings of freedom, or a painful death might speedily terminate his existence. The morning returned and the evening came, the year revolved and passed over him in the same state of suspense and silence. Or roused at some time by the hope of liberty, offered to him on the conditions of acknowledging his guilt, and declaring his accomplices, he indulged perhaps in a momentary transport: but finding, that though the terms of the agreement had been adhered to on his part, his keepers had spoken only to deceive him; he often sunk into an unchangeable melancholy, which at length overpowered his reason. It is not possible for the language of men to describe this torture of the soul, which those victims of tyranny were in some instances compelled to undergo. Many of the prisoners, however, bore their sufferings with greater fortitude, or rather from a peculiarity of constitution, or from the power of habit, they suffered less than others who were unhappily placed in similar circumstances. They even contrived to amuse themselves during their confinement; though the methods which they adopted for this purpose appear to indicate little else than the sad necessity of their condition. The histories of the Bastille are full of attempts made to train spiders by supplying them with food, and to avert the horrors of reflection by ascertaining the dimensions of the room, or counting in different directions the studs upon the door. Some have spent whole days in pouring water from one dish into another, or in disposing in fanciful arrangements the pieces of which their faggots were composed. After a certain time also the rigour of confinement was in some degree abated. The prisoners were allowed to walk daily for an hour in one of the courts, though still within the view of a soldier on guard. If any stranger appeared, they were obliged instantly to retire. By applying to the lieutenant of the police, they might obtain permission to attend mass, which was performed at least every Sunday in the chapel belonging to the castle. They were conducted separately from their apartments, and sat in covered niches, where they could hear without being seen. Some were allowed the convenience of pens, ink, and paper, and were permitted to write to their friends; but all their letters passed through the hands of the lieutenant of the police, by whom they were frequently opened and read, so that few of them reached the persons for whom they were intended. They likewise had the use of books from a library founded by a prisoner in the beginning of the last century, and augmented by the contributions of his successors. It consisted of about 500 volumes. Some of the captives were permitted to read in the library, while others had the books brought to them by their keepers. After much and frequent solicitation, Linguet, whose name has already been mentioned so frequently, obtained the use of mathematical instruments.

but on inspecting the case, he found that the compasses were exceedingly small, and made of bone.

There is one passage in the history of the Bastille, without which this branch of our article might be reckoned incomplete. We shall therefore give it in as few words as possible. Louis XVI. at the commencement of his reign, ordered the registers of the Bastille to be examined, and a number of prisoners to be set at liberty. The intelligence was received with surprise and unbounded joy. On one old man alone it produced these effects in a very inferior degree. He had been imprisoned for the space of 47 years; age had diminished his sensibility, and had, in some measure, reconciled him to his situation. When a strange voice announced his liberty, and permission to depart, he appeared to be stupified, at a loss what say, or how to act. Recovering himself, however, he slowly quitted his dungeon, and repaired to the street where he had formerly lived: But no vestige of his house remained, other buildings occupying the place where it stood. His family and near relatives were all dead, or gone into foreign climates. No one, even the most aged of those whom he accosted, either knew him, or could be brought to recollect any of the occurrences which he detailed, in order to assist their memory. A whole generation had passed away, and he found himself a stranger in the very city where he was born. An ancient domestic, to whom he was accidentally directed, at length recognised the features of the master whom he had served. From him he learned, that his wife had died thirty years before, in extreme grief, and that his children had disappeared, without any visible cause. The old man groaned under the weight of such accumulated misery; and presenting himself before the minister to whom he was indebted for his release, he bowed himself down and addressed him in the following words: "Restore me again to that prison from which you have taken me: I cannot survive the loss of my nearest relations, of my friends, and, in one word, of a whole generation. Is it possible in the same moment to be informed of this universal destruction, and not to wish for death? This general mortality, which to the rest of mankind comes slowly and by degrees, has to me been instantaneous, the operation of a moment. Whilst secluded from society, I lived with myself only; but here I can neither live with myself, nor with this new race to whom my anguish and despair appear only as a dream. There is nothing terrible in dying; but it is dreadful indeed to be the last." This speech had an obvious effect upon the minister. He ordered the ancient domestic above alluded to still to attend his master, as he alone was able to converse with him on the subjects of his lost children and friends. The old man would talk of nothing else; for he avoided all intercourse with the world, and continued to live in the midst of Paris as much a stranger to society as when he was confined in the dungeons of the Bastille, till death put an end to his existence.

We may now enquire what were those crimes for which the severe retribution of the Bastille was destined? Were the dungeons of that castle, which stood for ages the terror of France and the disgrace of Europe, filled with assassins and traitors, with wretches who had

plotted against the welfare of their countrymen, and longed to riot in the plunder which they might obtain? If this were the case, France must have been regarded as peopled with conspirators; and that nation, which of all others most readily submitted to the yoke of despotism, must have been almost wholly composed of rebels and murderers. But the case was far otherwise. The dungeons of the Bastille were often filled, especially in later times, with innocent and peaceful citizens, who had unjustly become the objects of punishment, or with humble individuals, who, from their inferior situation and limited means, could never have been formidable to the state.* Did a man, conscientious in the discharge of his duty, refuse to violate the principles of integrity and honour at the command of the minister? he was instantly sent to the Bastille. Had any one the misfortune to incur the displeasure of a favourite mistress? he experienced a similar fate. If any purpose was to be served, or any passion to be gratified, even a word or a look was reckoned a sufficient cause of imprisonment. And an individual once shut up, might be allowed to remain for years in his cell, not because he continued to be suspected or feared, but because he was forgotten. The consequence of all this was, that men lived in constant apprehension: They "were denied that inestimable privilege, the free communication of their thoughts and sentiments: Dissimulation became necessary for their safety. The towers of the Bastille seemed to stand aloft over the kingdom, for the purpose of scaring its inhabitants;" and on each of them might have been written the inscription sometimes to be found on grave-stones, *hodie mihi, cras tibi*.

It is remarkable, that the first prisoner confined in the Bastille was d'Aubriot, the architect who planned it. During the prosecutions on account of religion in the reign of Louis XIV., when the well-known edict of Nantz was revoked, and during the contests with the Jansenists under the administration of Cardinal Fleury, the annual number received was very great. Many of these were tried and executed; some perished in confinement, and others were set at liberty. Of all the prisoners, however, the most celebrated is the "man in the mask." He was brought from the island St Margaret on the 18th September, A. D. 1698, and immediately shut up in the Bastille. The mask, which he wore, was made of black velvet, and fitted with springs of steel, so that it was unnecessary to take it off when he ate. On his journey to Paris, those who conducted him had orders to put him to death if he made the smallest attempt to shew his face, or otherwise to discover himself. Historians have been so lost in probabilities while endeavouring to ascertain his name and quality, that to this hour it is doubtful who he was. There is reason to believe that he was a person of the first condition. He could read and write; attainments not common at the period in which he lived. He understood music, and could play on the guitar. When at St Margaret, the Marquis de Louvois, who went to visit him, spoke to him standing with every testimony of respect: and, in the Bastille, the governor very rarely sat down in his presence. His dress was sumptuous, and his table furnished with the utmost care. On one occasion he wrote something with his knife upon a plate, and threw it out

* In the register of prisoners for the year 1687, we find the name of Laurence Lemiere, *shoemaker*, who was confined, together with his wife, "for dangerous discourse about the king." And in the register for 1699, that of John Blondeau, a hermit, "a suspicious person."

from the window of his apartment; but the plate was found by a fisherman who could not read, and who carried it without delay to the governor. The ignorance of the fisherman was the cause of his safety; for after a few days confinement the governor dismissed him, saying, "You may rejoice that you cannot read." It is probable that the name and some account of the unknown person were written on the plate. This happened at St Margaret. The illustrious and unfortunate prisoner with the mask, died in the Bastile A. D. 1704. Immediately after his death, his clothes, lincin, and all his apparel, were burnt with the most anxious care: the very floor of his apartment was scraped and taken up, and every vestige of his existence annihilated. The most plausible conjecture with respect to him is, that he was the twin brother of Louis XIV.; but for the reasons on which this conjecture is founded, as well as for other information, we must refer to the *History of the Bastile*. Appendix No. vi.

In the heat of the French Revolution, the Bastile was taken by the mob of Paris, and afterwards levelled with the ground. There were only seven prisoners found in it; these were Tavernier, (deranged) Pujade, La Roche, Caurege, Bechade, (imprisoned on account of a forgery in which they were engaged) Le Comte de Solages, (arrested at the request of his father) and White, an Englishman, (deranged.) Reflecting on the memorable achievement, Mr Cowper breaks out into the following apostrophe, with which we shall conclude the article:

Ye horrid towers, the abode of broken hearts,
Ye dungeons and ye cages of despair,
That monarchs have supplied from age to age
With music, such as suits their sovereign ears:
The sighs and groans of miserable man:
There's not an English heart that would not leap
To hear that ye are fallen at last!

BASTINADO, **BASTONADO**, or **BASTONADE**, a kind of punishment inflicted with a rod, or staff. This mode of punishment was common among most of the ancient countries, and is still practised in many of the eastern nations. In all the provinces of the Ottoman empire, the bastinado is the common punishment for theft, and other delinquencies of a more trivial nature. The criminal is stretched on his back upon a board, with his hands tied, and his ankles confined by a wooden machine. The legs are then raised, while two men, one placed on each side, alternately beat the bare soles of the feet, with a rod about the size of a small walking stick. The bastinado is sometimes a very slight punishment, but is inflicted at other times with barbarous cruelty. The number of strokes is specified in the sentence, amounting sometimes to 400 or 500; but it is usual for some person present to intercede in favour of the offender, before he has received the full number; for the punishment is inflicted, if not in the judge's presence, at least within his hearing. This punishment is accompanied likewise with a kind of fine; for the person on whom it is inflicted pays so much for every blow, both to him who gives and to him who counts them. In China, the bastinado, though sometimes very

smartly applied, is the slightest kind of punishment, used only in case of very trivial crimes. It is often inflicted, by the emperor's direction, on his courtiers; who receive it as a particular mark of his gracious and paternal care, and are afterwards received into authority, and treated with distinguished respect. Every mandarin has the privilege of inflicting this punishment at pleasure, either when he administers public justice, or when any person neglects to greet him with the accustomed salutation. When he sits in judgment, or gives a public audience, a bag, filled with small sticks, lies on a table before him, and he is surrounded by a number of petty officers, provided with the baton, or pan-tsee, employed in bastinading. Taking from his bag one of the little sticks which it contains, he throws it down on the hall, towards the culprit whom he wishes to be chastised. His officers seize the criminal, and stretch him at full length, with his belly towards the ground; he is stripped bare to the heels, and receives five smart blows from the most athletic of the attendants; another succeeds, and bestows an equal number, if the mandarin pulls forth another small stick from the bag, which is the signal when he wishes the punishment to be continued. The person thus chastised then throws himself upon his knees before the judge, inclines his body three times towards the ground, and thanks him for the fatherly charge which he takes of his education. See Guer's *Mœurs et Usages des Turcs*, vol. ii. p. 162. Russel's *Alippo*, vol. i. p. 334. Grosier's *China*, vol. ii. p. 52. Chantreaux's *Travels in Russia*, vol. i. p. 117. (μ)

BAT, an animal of the mammalia tribe, an account of which will be found in the article **MAMMALIA**. The bats in Senegal are eaten by the negroes, and are generally as large as pigeons. Their wings are very long, and they are furnished with five or six pointed hooks, by which they fix themselves together, and hang like large bundles from the branches of trees. Mr Bolingbroke, in his voyage to Demarara, mentions a very singular anecdote of the bats of that country. When the inhabitants are asleep in their hammocks, and their feet accidentally uncovered, the bats often open the veins of their feet without disturbing them, and suck till they are satisfied. When the victim of their attack awakes, he finds himself faint, and his feet bathed in blood. These animals make similar attacks upon cattle. See Durand's *Voyage to Senegal*, chap. v. and Bolingbroke's *Voyage to Demarara*, chap. xii. See also *Vespertilio*. **MAMMALIA Index**. (π)

BASTION. See **FORTIFICATION**.

BATALIA, a small village in Portugal, about 60 miles north of Lisbon, where a famous monastery, the place of sepulture of the royal family, is situated. Don John, the first of the name, and tenth king of Portugal, on being attacked by the king of Castile with a powerful and greatly superior army, invoked the protection of the Virgin, vowing to consecrate a magnificent monastery to her honour, should he prove victorious. Having defeated his adversary, and reduced the whole kingdom to tranquillity, he founded the monastery of Batalha in 1385, which he designed should be the most splendid in all Christendom. It was at first endowed for 30 monks, but there are now 44. The architect under whom the monastery was built is said to have been an Irishman, named Hacket; and, at this day, it is one of the most elegant Gothic edifices in Europe. It is adorned with a profusion of ornaments in the richest taste.

some of which are hieroglyphical, or mystical, and inexplicable by the learned. These are particularly conspicuous on the mausoleum of the founder. On the tombs of several illustrious branches of the royal family, interred here during the 15th century, besides figures merely ornamental, is seen the order of the garter, which they had obtained from the sovereigns of England. This monastery was amply endowed, both by foreign princes and those of Portugal. When the emperor of Constantinople, *Emanuel Paleologus*, was at Paris, in 1401, soliciting the assistance of the Christian powers, he transmitted a singular collection of precious relics, along with a certificate respecting them under his own hand, which we believe is still extant. In 1755, the edifice was damaged by the fatal earthquake which destroyed the capital, and the spire of the founder's mausoleum was overthrown. For a more ample account of this structure, which is considered a model of pure Gothic architecture, see *Murphy's Plans, Elevations, Sections, and Views of the Church of Batalha*; *Louis de Sousa's History of the Royal Monastery of Batalha*; and *Link's Travels in Portugal*, chap. xxv. p. 280. (c)

BATAVIA, the capital of the Dutch settlements in the East Indies, is situated on the north coast of the island of Java, at the mouth of the river Jacatra. It lies in the bosom of a large and commodious bay, which is so sheltered from the violence of the wind, by eighteen islands scattered along its mouth, that it is considered one of the safest harbours in the world, and is so capacious, that a thousand sail of ships may ride there in safety. The city is surrounded with a broad wall, fortified by twenty-two bastions, and a deep moat which can be filled at pleasure with water from the river. All the avenues on the land side are protected by forts and redoubts, erected at a considerable distance from the town. These are mounted with brass cannon, and are built entirely of square stones. The approach by sea is commanded by a horn-work, commonly called the "Water fort," mounting fourteen guns and two howitzers; and the entrance of the river is defended by the citadel, and several strong batteries of six or seven guns each. There is also a fortification upon Onroost, one of the islands in the mouth of the bay, which completely commands the channel forming the principal passage into the road. Upon this island the Dutch have established extensive dock-yards, where every thing necessary for building, equipping and preserving the company's ships is provided in such abundance, that they can build, repair and refit their vessels, without the least loss of time, and in the most complete manner. The citadel, situated on the east bank of the river, is a regular square fortification, built of coral rock, and flanked with four bastions. It contains the palace of the governor general of the Indies, as also the apartments of the counsellors, and other principal officers of the company. The arsenals and magazines are generally well furnished, and always contain stores and ammunition sufficient for a regular siege. The city itself, though it has been highly admired for the beauty of its buildings, and on account of its immense trade, has acquired the appellation of the "Queen of the East," contains nothing of elegance or design particularly worthy of notice. Its town-hall, its hospitals, and its churches require no description. They are such as we see every day in our own country. The streets are straight and regular, overshadowed and embellished with large trees, which are planted on each side. They are twenty in number, and run from 114 to 204 feet in length. The

houses, which are chiefly built of brick, are commodious and handsome. The windows and doors are wide and lofty, and the ground floors are laid with flags of marble, which, being frequently sprinkled with water, produce a coolness in that burning climate particularly refreshing. The form of the city is an oblong square, about three quarters of a mile long and half a mile broad, intersected by the river Jacatra, which runs through the middle of it, from south to north, and which is crossed by three bridges. In its passage it forms fifteen canals of running water, which are all faced with free stone, and whose banks are beautifully adorned with evergreen shrubs and plants. The breadth of the river within the walls is from 160 to 180 feet. At its mouth are two large piers of wood and brick work, running about half a mile into the sea, between which 100 slaves are constantly employed in clearing out the mud which is washed from the town, and which otherwise would choke up the channel of the river. The suburbs are very extensive and populous, and are inhabited chiefly by Chinese, and the natives of the island.

The environs of Batavia, to a considerable extent, present one universal garden, intersected with rivulets and canals, overshadowed with lofty trees, and interspersed with magnificent villas. The Dutch have here indulged their national taste to its full extent. Every spot is covered with verdure, and the most luxuriant foliage. Whatever can satisfy the palate or delight the sense, is produced in abundance. Fruits of every description grow almost spontaneously, and without culture; and could we but forget the danger which life is every hour exposed to, from the insalubrity of the climate, we might regard this place as the most delightful region of the world. But in the midst of plenty, beauty, and gaiety, every countenance indicates debility and languor. To use a strong expression, it is the work-shop of death. There is pestilence in the air, and poison in the water. The atmosphere is continually infected with deleterious vapours, which rise from the surrounding swamps and morasses; and the trees, with which the quays and streets are crowded, impede the free circulation of the air, and retain the putrid effluvia, which otherwise would in some degree be dissipated. Fevers, which are here the general denomination for all kinds of illness, are continually raging in the colony. The disorder at first is a tertian ague, which, after two or three paroxysms, becomes a double tertian, and then a continued remittent, that frequently carries off the patient in a short time. Hence it happens that preventive medicines are taken as regularly as food, and every one expects the returns of sickness, as we do the seasons of the year. The inhabitants have thus become familiar with death, and hear of the loss of a friend without either surprise or concern. Of strangers who come to settle at Batavia, three out of five are reckoned to die the first year; and it appears, from calculation, that the company lose annually one-fifth of their servants. The climate, however, is not the only enemy to Europeans: the mortality is greatly increased by the voluptuousness and luxurious effeminacy in which many of them indulge. The change from a life of temperance to that of irregular indulgence, added to the sudden transition from a northern region to the torrid zone, independent of the noxious circumstances which are peculiar to the climate, cannot fail to produce these fatal effects for which this place is so remarkable. And such is the general apprehension of the unhealthiness of this colony, that even the temptation of

quickly amassing a splendid fortune is insufficient to induce those who can reside at home with any comfort, to seek a settlement in Batavia. Many offices and professions are thus necessarily entrusted to persons little qualified for fulfilling their duties; and it is worthy of remark, that one of the clergymen and the principal physician had originally been barbers.

Of a population, amounting to 110,000, exclusive of women and children, scarcely 5000 are Europeans; and of these, not one-fifth are Dutch, the greatest number being Portuguese and French. The rest are composed of a great variety of Indians, who are all under chiefs of their own nation, such as, Chinese, Javanese, natives of the island, Malayans, Amboynese, Mardykens, Baliens, Bouginese, Masassars, &c. The Chinese are the most numerous enemies to idleness. They seem born for the bustle of active commerce. They are indefatigably industrious, and will submit to any drudgery, however laborious, that is attended with a certainty of gain. Cunning, however, and deceitful to the last degree, they take a pride in imposing upon Europeans; and boasting of their dexterity, they tell you, that the Dutch have one eye, but the Chinese have two. They keep all the shops, and most of the inns in the city, and are in general the farmers of the duties, excises, and customs. The Javanese apply themselves chiefly to agriculture and ship-building; and the Malayans to fishing. This last is a most wicked and profligate race. They profess to be Mahometans; but are absolutely void of morals, and would commit a murder for the most trifling reward. Their last chief was publicly whipt and branded for his villanies: since which they have been ashamed to choose another. The Amboynese, a bold, boisterous, and turbulent people, are not allowed to live in the city, but are confined to a certain quarter of the suburbs. They are generally employed in building houses of bamboo, with windows of split-cane, which are very neatly wrought in different figures. The Mardykens are of various trades, as merchants, gardeners, graziers, poulterers, &c. Few of the free Indians, however, are employed in domestic or menial services. These are chiefly employed by slaves, which are annually imported from Sumatra and Celebes.

All the dominions which the Dutch possess in the East are governed by two supreme councils; the council of the Indies, and the council of justice, both of which are fixed at Batavia. To the first of these belongs the entire direction of public affairs; and to the latter, the administration of justice in all its branches. But the citizens and free-merchants are amenable only to the tribunal of the city of Batavia; which is composed of eight aldermen and a president, who is always a counsellor of the Indies. The governor-general, who presides in the council of the Indies, is in a manner the sovereign of all the countries belonging to the company. He possesses unlimited authority; is allowed a court, and most of the honours of majesty; and so great are the legal emoluments of his office, that without oppressing the people, or burdening his conscience, he is able to raise an immense fortune within two or three years. He is, however, removeable at the pleasure of the directors at home, and, in case of treason, or other enormous crimes, the council of justice have a right to seize his person, and call him to account.

The ecclesiastical government of Batavia resides in eleven members of the reformed religion. Liberty of

conscience is granted to every denomination of religionists, though not liberty of worship: Mahometans and Pagans are tolerated by government; and even the Chinese have their temples, in which they worship the Devil under the figure of a gigantic colossus, sitting cross-legged, with an enormous belly hanging over his knees; but the exercise of the Roman Catholic religion is obstinately prohibited.

The regular establishment of troops at this colony seldom exceeds 3000 men, of which 700 only are Europeans; yet very few of these are furnished by the Dutch. They are chiefly Germans, many of whom it is said, have been kidnapped into the service. The irregulars are very numerous, consisting of Chinese and natives of the island, who are commanded by their own officers. All the white inhabitants, however, are trained to the use of arms; for no person can settle here but as a soldier in the company's service, and he must serve a certain time before he is allowed to enter into any branch of trade. But the whole of their force is very inefficient for the defence of the settlement; and the Dutch depend more upon the insalubrity of the climate, than the strength of their arms, for repelling a hostile invader. The whole establishment of the company in 1777 consisted of 615 persons in civil, and 35 in ecclesiastical employments, 99 surgeons and assistants, 125 belonging to the artillery, 875 seamen and marines, 1571 soldiers, and 903 mechanics; in all, 4221 Europeans, besides 703 natives in their service.

The bay and harbour of Batavia are excellently adapted for commercial navigation. The trade consists chiefly in the valuable productions of the island, such as pepper, rice, sugar, cotton, and indigo; and as Batavia is the emporium where all the merchandize of the Dutch company in India is deposited, the import and export duties are very considerable. Yet the revenues of the colony are altogether inadequate for its support. This city being the seat of government, the charges of the Company's civil establishment, as also of the military and marines, are defrayed out of the treasury of Batavia. On this account a considerable balance appears every year against it; and in 1779 the charges exceeded the receipts by 51,327*l*.

The establishment of this colony upon the ruins of a royal city, in opposition to the efforts of the English, and afterwards to the united forces of the populous empire of Java, and its consequent prosperity, affords us a striking example of what may be effected by courage and perseverance. When the Dutch first visited this island, the residence of the king of Jacatra was an inconsiderable village pallisadoed with bamboo canes. Having entered into an alliance with this prince, they contracted with him for the produce of his little territory, which consisted chiefly of pepper. But afterwards suspecting him of a breach of faith, they built a strong fort in the neighbourhood to awe him into justice. This raised the jealousy of the English, who had also some correspondence with the people of Jacatra, which soon kindled into open war. The fleets of the two nations engaged at a short distance from the fort, when the Dutch were completely defeated. The English then took possession of Jacatra, and upon an eminence in the middle of the town established a magazine, which they fortified with a considerable number of heavy cannon. Vanden Broecke, the Dutch commander of fort Maurice, being hard pressed for want of ammunition and

provisions, threw himself under the protection of the governor of Bantam, who immediately dispatched 2000 men to his assistance. The Bantamese officer entered Jacatra, stript the king of all ensigns of royalty, and drove him with his family, helpless and poor, to a distant corner of the island, where he dragged out his existence in the humble condition of a fisherman. Peace being soon after concluded between the two Companies, the English retired from the island, leaving the Dutch in possession of Jacatra, but so completely under the power of the Bantamese, that Vanden Broecke and seventy of his men were carried prisoners to Bantam. This unfavourable aspect of affairs, however, was soon changed by the arrival of a Dutch squadron. Commodore Koen after his defeat had retired to Amboyna, and having received a strong reinforcement, returned in 1619 with a fleet of seventeen sail and a considerable body of troops. He ravaged and entirely destroyed the town of Jacatra; and marching his forces to Bantam, demanded the restitution of Vanden Broecke and his companions. The Bantamese governor was in no condition to make resistance. Koen returned immediately to fort Maurice; and upon the ruins of Jacatra, in the midst of fens and morasses, and under a vertical sun, he laid the foundation of the new city of Batavia. National taste and national prejudices seem to have dictated, in a great measure, the choice of this situation. The Dutch were partial to the swamps of their native country; and they fondly indulged the idea of enjoying, in an opposite quarter of the globe, the muddy canals and shady walks of Amsterdam. The plan, however, was so well contrived, and, notwithstanding the local disadvantages, the execution was so prompt and successful, that Batavia speedily became, and has ever since continued, the capital of the Dutch conquests and settlements in the East. But this colony had not only to encounter difficulties at its first establishment; it continued during its infancy to experience the most decided opposition, both from their countrymen at home, and from the inhabitants of the island. The emperor of Java, who had beheld with satisfaction the jealousy between the Dutch and English, and had been an idle spectator of their hostility, now began to take alarm at the growing prosperity and gradual encroachments of his ambitious neighbours. His fears prompted him to the most decisive, but detestable measures. He attempted to take off governor Koen by secret assassination: but that design failing, he drew together an immense army, and determined to extirpate these daring intruders. In the beginning of the year 1629, Batavia was invested by 200,000 Javanese; but the Dutch works were defended with such courage and conduct, that, after a siege of several months, they were obliged to retire, broken and discomfited. The good fortune of the colony in this enterprise, however, was greatly overbalanced by the death of the governor-general, to whose wisdom and activity it had owed its existence and preservation; and they would probably have felt the effects of his loss more severely, had not a diversion happened in the island, which relieved them in a great measure from the apprehension of present danger.

The governor of Bantam having revolted from the Emperor of Java, assumed the title of king, and was supported in this quality of an independent prince by the government of Batavia. Two separate interests being thus formed in the empire, the Dutch, by dexterously playing the one against the other, were enabled

not only to maintain their own power, but considerably to extend their territory; and though both sovereigns bore an invincible hatred to the colony, yet by taking advantage of their mutual animosity, they soon became so formidable as to defy the resentment of either. Not contented, however, with this precarious security, which the united efforts of the empire might annihilate, they contrived a scheme of freeing themselves entirely from future apprehensions, by getting into their hands the persons of the two sovereigns of the island. This scheme, the offspring of the most refined policy, was prosecuted by means the most deceitful and unjustifiable, and in the space of a few years was actually accomplished. A Dutch fort, manned with a strong garrison, and well fortified with cannon, overawes the capitals of Bantam and Java. A European guard even resides in the palace of their sovereigns, out of pure tenderness and respect; and they are made to believe, that these evidences of their subjection are solely for their honour and defence. The Dutch, however, have not been able to keep the emperor of Java in entire and strict submission. Wars have frequently arisen from a disputed succession to the throne; and they are constantly obliged to cajole him by splendid embassies, and costly presents. But they have no apprehension from his power. They have, in a manner, the absolute direction of his affairs, and are in possession of almost the whole trade of his dominions. As for the king of Bantam, he is as completely at their devotion, as the king of the Hottentots was at the Cape of Good Hope. The colony had thus become in a great measure masters of the island. Batavia had yearly increased in strength, beauty, and opulence, and could vie in splendour and power with the chief settlements in India. All fears of foreign hostility were now allayed, and they began to indulge the hope of domestic peace and settled security. But the natives were far from being reconciled to their authority. They made repeated efforts to drive them from the island, and to restore their sovereigns to independence. The avarice and injustice of the Dutch had sown the seeds of disaffection, and had excited even the hatred of their own subjects. And at a time when seeming tranquillity reigned around, they were upon the very brink of destruction, and thousands waited only the signal to take vengeance on their oppressors. A conspiracy of a most daring and dangerous nature had been for four years forming in the very heart of the settlement. It had been carried on with such determined perseverance, and managed with such amazing secrecy, and so great was the number concerned in it, that its authors had reason to expect the most complete success. Catadia, a Javanese, and Peter Erberfeldt, a burges of Batavia, were the original contrivers of this diabolical design, which was to surprise the city, and to put every European and Christian to the sword. The execution of their purpose was fixed for the first morning of 1722. The order of attack was prepared and delivered to the chiefs of the conspiracy; 17,000 men were engaged to ensure its accomplishment; and they waited only the signal for striking the final blow, when on the day preceding this intended massacre the conspiracy was divulged, just in time to prevent the dreadful catastrophe. Twenty of the principal conspirators were seized without any noise, and all necessary precautions taken in case of any commotion in the city; but the confederates were so thunderstruck at the discovery, that not the least attempt was made for their rescue. The Batavian government

that they might not drive these people to desperation, prudently declined proceeding against the other accomplices, but were contented with the traitors whom they had already in their power. Upon these, however, they took the most exemplary vengeance, and inflicted such a punishment as should deter all others from imitating their crimes. Erberfeldt and Catadia were condemned "to be extended and bound each of them upon a cross, to have their right hands cut off, and their arms, legs, and breasts pinched with red hot pincers, till pieces of the flesh should be torn away. Their bellies were then to be ripped from bottom to top, and their hearts thrown in their faces; after which their heads were to be cut off, and fixed upon a post; and their bodies, torn in pieces, were to be exposed to the fowls of the air without the city, in whatever place the government should please to direct." *Sentence contre Pierre Erberfeldt, et ses complices, prononcée à Batavia en 1722.*

This terrible sentence, which scarcely the imminence and extent of the danger could justify, was executed without the least mitigation. Its severity, however, had not the desired effect. The growth of the treason was stopped, but the roots still remained; and eighteen years after the conspiracy of Erberfeldt, the Dutch proceeding upon mere supposition, committed one of the most inhuman massacres that has ever disgraced the annals of any nation. On the memorable morning of the 9th of October 1740, an order was issued by the governor and council, for immediately putting to the sword all the Chinese that could be found in the city. The garrison, and the sailors who were brought from the vessels in the roads, were tempted by the promise of plunder to execute the bloody edict. The houses were broken open, and the sleeping victims were torn from their beds and killed without distinction. In a short time the streets, rivers, and canals, were covered with dead bodies, and in some places the blood ran over the shoes of the murderers. A more shocking and horrible spectacle was never exhibited to mortal sight; and in this dismal tragedy there fell, according to the acknowledgment of the Dutch, no fewer than 12,000 Chinese; but according to other accounts, 30,000 men, women, and children. Of this transaction our limits will not admit of a more detailed account. Indeed no certain information can be obtained on the subject. The Dutch, it is true, have framed a story full of rebellion, insurrections, massacres, and fire. They have told us, that the Chinese had entered into a conspiracy to raise their chief to the government of Batavia, and to massacre all the Europeans in the colony, except the governor and director-general, whom they intended to preserve for carrying umbrellas over the heads of the new governor and his lady! that the evening before the massacre, 50,000 Chinese had attacked the city, set fire to the suburbs, and endeavoured to excite their countrymen within the walls to rise against the Dutch; and consequently that they were compelled, by the urgency of the danger, and as the only means left for securing the public safety, to have recourse to this most expeditious and effectual remedy. But though they have been openly charged with falsehood and exaggeration, and have even confessed, that in their narrative many particulars were omitted, and promised a more full and distinct relation; yet these charges were never answered, nor has the promised relation ever appeared. All the accounts which have been received of this dismal scene, instead of explaining, have served

only to cloud a transaction, dark and ambiguous, and which we doubt will never be brought to the public view in its true colours. From the subsequent conduct of the colony, however, we are warranted by pretty strong evidence to conclude, that they were actuated in this measure by very different motives than what they avowed to the world; and throughout the whole of this transaction we can easily trace the same grovelling spirit and detestable thirst for wealth, which dictated the horrid outrage against our countrymen at Amboyna. But the massacre, as soon as it was known in Europe, was also openly ascribed to the avarice of the governor, supported by such as were deeply indebted to the Chinese, who thought that cutting their throats was the easiest and most expeditious method of settling accounts; and the Dutch, so far from attempting to discredit the rumour, rather seemed willing to free themselves, by throwing the odium upon the governor. He was seized on his way home with all his effects, amounting to half a million sterling, and carried back to Batavia, to abide a trial for the shameful abuse of his authority, and where he remained a prisoner until his death. The 50,000 Chinese who, it is said, continued to waste with fire and sword whatever they met with on the mountains, so far from being objects of terror and alarm to the Batavians, were invited by a general amnesty to return to the settlement, and in a short time they became as numerous as ever. Order and tranquillity having been restored to the distracted colony by the firm and wise administration of the new governor, the inhabitants soon lost all apprehensions of any future disturbance. The government, however, were afraid lest the perpetration of this outrage should excite the indignation of the emperor of China, and interrupt the amicable correspondence which had long subsisted between that country and Batavia; and, in the following year, sent deputies to apologise for the measure, on account of the necessity of the case. But the emperor, instead of expressing his horror and displeasure at the injuries and insults offered to his countrymen, calmly replied, "that he was little solicitous about the fate of unworthy subjects, who, in the pursuit of lucre, had quitted their country, and had abandoned the tombs of their ancestors." The Batavians, having again assumed their ancient dominion, continued to exercise it with more prudence and lenity. Nothing, however, has happened in the settlement worthy of recording. From that time it has rather been in a declining state, and, especially within these 50 years, has considerably fallen off both in population and opulence. When Sir George Staunton visited this place, many of the houses were untenanted, which by no means indicates a flourishing colony. The observatory formerly erected here is now entirely neglected, but the society of arts and sciences, founded under the administration of De Klerk, still subsists. The first volume of its memoirs was printed at Batavia in 1779. As Batavia derived its importance more from being the emporium of the Dutch commerce in India, than from its own resources, its decay may easily be accounted for by the severe losses which the Dutch have of late sustained in that quarter; and we may with safety assert, that as long as Britain maintains her dominion in the east, Batavia will never recover her ancient splendour and magnificence. East Long. 106° 51' 15", South Lat. 6° 10'. See *Mod. Un. Hist.* vol. x. p. 301—368. *Stavorinus' Voyages*, vol. i. and iii.

BATAVIAN REPUBLIC. See HOLLAND.

BATCHELOR. See BACHELOR.

BATCHESERAI, more properly BAKTCHESERAI, or BACTCHESERIA, the ancient residence of the Khans of the Crimea, is situated, like Matlock in Derbyshire, on the rugged flanks of two high mountains, and on the interjacent valley, which is watered by the rivulet Dshauruk-su. The hanging gardens, the towers of the mosques, the black Italian poplars, the terraces, and bubbling fountains, contribute to the beauty of this picturesque town. The principal street, which is nearly a mile and a quarter long, consists of two rows of miserable wooden shops, which are kept by Karait Jews, who live at Dschoufoukale, a town about a mile and a half from Batcheserai. They repair to their shops on horse-back every morning, and return to their houses in the evening. The palace of the Khan is situated in the centre of the town near the Dshuruk-su, on the edge of a quay. A stone bridge across this rivulet conducts the traveller to a gate opening into the outer court; on the left hand is a large and handsome mosque which belonged to the Khan, and farther on are the stables, while the palace appears on the right. It is only one story high, having several fronts of different altitudes, with roofs of various forms. On the slope near the palace is a fruit garden, divided into four terraces. The cemetery which contains the bodies of the khans and their families is behind the mosque. The favourite residence of the khan was a magnificent edifice, delightfully situated beneath a mountain on the slope of a beautiful vale; but the wanton barbarity of the Russians was fatally displayed in the total destruction of this and the other ornaments of Batcheserai. The fountains of this city, which amount to 75, are seen in every part of the town discharging the most limpid water, and the Tartars repair to them four times a day to perform the ablutions which their religion demands.

Batcheserai contains about 31 mosques, a few cutlers shops, a manufactory of red and yellow leather, and some of felt carpets. The houses are built of wood and ill-baked bricks, having wooden piazzas and sloping roofs of red tile. Population 5776, consisting of Tartars, Jews, and Arminians. A full account of the palace will be found in Dr Clarke's *Travels in various countries of Europe, Asia, and Africa*, Part i. p. 464—485; a work full of new and interesting information. See also *Travels in the Crimea*, &c. in 1803 by Reuilly, who visited this country after Dr Clarke; Pallas's *Travels*, vol. ii. p. 29. and DSCHOUFFOUKALE'. (*τ*)

BATCHIAN, BACHIAN, BAKIAN, or BAIAN, is the largest of the lesser Molucca islands, about 12 leagues in circumference. It is under the dominion of a sultan pensioned by the Dutch, who is likewise sovereign of Ouby and Ceram, with Goram, a little isle south-east of Ceram, containing 13 mosques, and reckoned the most eastern boundary of the Mahometan faith. This island abounds with all kinds of animals, and fruits of every species; and in tobacco and sago, on the latter of which the inhabitants subsist. The historian of the conquest of the Moluccas describes Batchian as a wild and desert country, in consequence of the indolence and oppression of the inhabitants, though, at the same time, capable of high cultivation. The cloves of Batchian were once reckoned the best in the Moluccas; but they

are no longer collected in any quantities. The island contains a burning mountain; and immense rocks of coral decorate its shores. East Long. 125° 5', and S. Lat. 0° 25'. (*j*)

BATGAN, a city of Hindostan, in the kingdom of Nipal, which forms an immense plain that separates the mountainous tract called Bindachul from the extensive Alpine region called Hamachul. Batgan is the third principal city of this kingdom, and lies about ten miles south of the capital Catmandu. It is said to contain about 12,000 families; but this estimate is obviously exaggerated. East Long. 85° 15', and North Lat. 27° 20'. See Guiseppi Bernini's *Account of the Kingdom of Nipal*, in the *Asiatic Researches*, vol. ii. p. 308. (*q*)

BATH, the *Aque Solis* of the Romans, is a city of England, in Somersetshire. It is beautifully situated on the river Avon, on the side of a narrow valley, bounded by hills on the north, south, and south-west, and widening on the north-west into rich and extensive meadows.

After the Romans had reduced to subjection the Belgic colonies and the western parts of Britain, they were allured to the spot where Bath now stands by the excellence of its situation, and by the warm springs which spontaneously flowed from the earth. Finding that they could indulge without trouble or expense in all the luxuries of the warm bath which they had enjoyed in their native country, they dignified the hot springs with the appellation of the "Waters of the Sun." The first detachment of the second legion was stationed at Bath; and after the successive arrival of other divisions of the Roman army, the town increased in size till it became the principal city in that part of Britain which was subject to the Romans. The form of the city was nearly pentagonal, having its greatest breadth about 380 yards, and comprehending an area of nearly 4000 yards. The wall which enclosed it consisted of layers of stone, brick, and terras, about ten feet thick, and twenty feet high; and were flanked with a tower at each angle. Two grand streets, intersecting each other, and dividing the city into four parts, terminating in four gates, facing the cardinal points of the horizon. Temples and magnificent baths, the remains of which were discovered in the year 1755, combined to give elegance and splendour to this Roman station. Bath underwent many changes during the numerous wars and revolutions which mark the history of England, but most of them are of too insignificant a nature to be detailed in a work like this.

Bath has been long regarded as one of the finest towns of England, on account of the beauty of its streets and the magnificence of its public buildings. The Royal Crescent, which is of an elliptical form, and contains thirty houses, forms one of the finest assemblage of buildings in the kingdom. A single order of Ionic pillars supports the superior cornice, and the houses command a delightful prospect of the greater part of the city. Queen-square, Marlborough Buildings, Lansdown Crescent, Catherine Place, and River Street, are also remarkable for their elegance and excellent situation. The old assembly rooms, built in 1750, are about 90 feet long, 36 broad, and 34 high, and enjoy a beautiful prospect of the Avon, and the surrounding hills. They are surpassed, however, in size and elegance by the new assembly rooms, which were opened in 1771. The ball room is 106 feet long, 42 feet wide, and 42 feet high. One of the card rooms is an octagon, 48 feet

in diameter; and the other is rectangular, being 70 feet long, and 27 feet wide. The Theatre was designed and erected in 1768, by Mr Palmer, who obtained his majesty's letters patent for dramatic entertainments. The guildhall, of which the foundation stone was laid in 1760, is a very handsome building; and the common council room is adorned with several portraits of public characters. The circus is a grand circular pile of uniform buildings, with three openings at equal distances, leading into different streets. The fronts of the houses are decorated with three rows of columns, in pairs, of the Doric, Ionic, and Corinthian orders, having the frize adorned with sculpture; and in the centre is a reservoir of water, collected from the surrounding springs. The General Hospital is an elegant building, 100 feet long and 90 deep, and capable of accommodating 100 patients. It is supported by voluntary contribution, and receives from every part of the world any invalids that desire benefit from the Bath waters. St John's Hospital, founded in 1180; St Catharine's Hospital; Bellot's Hospital; the City Dispensary and Asylum; the Casualty Hospital; the Puerperal, or child-bed charity; and the Stranger's Friend Society; are the other benevolent institutions, which the wealthy inhabitants of Bath have provided for the relief and comfort of the poor.

Besides the public grammar school, and other establishments for the instruction of the ignorant poor, Bath contains two excellent institutions for the promotion of science and the arts. The Bath and West of England Society was established in 1777, by Mr Edmund Rack, for the encouragement of agriculture, manufactures, commerce, and the arts. The volumes of its Transactions, which have already appeared, evince the utility of the institution, and the activity of its members. The Philosophical Society was established in 1799, for the diffusion of science and literature.

The principal churches in Bath are the Abbey Church, St James's Church, St Michael's Church, and Walcot Church. The Abbey Church, which has the form of a cross, is about 210 feet long, from north-east to west, and 126 from north and south, with a breadth of 72 feet. A magnificent tower, about 162 feet high, rises from the centre of the building, and gives a dignified appearance to this beautiful specimen of English architecture. The richness of the west window, the arched doorway, which forms the western entrance, the roof of the building, and the marble monuments within, are deserving of particular attention.

There are here four public baths, viz. the King's Bath, the Queen's Bath, the Cross Bath, and the Hot Bath. The King's Bath is 65 feet long and 40 broad, and contains more than 346 tons of water when it stands at its usual height. The spring which fills it rises from the centre, and is inclosed by a brass hand-rail of an octagonal form, while the whole bath is surrounded by a beautiful colonnade of the Doric order. The Queen's Bath, which is attached to the former, and receives its water from it, is a basin 25 feet square. The Cross Bath, which was so called from a cross erected in its centre by the earl of Melfort, is of a triangular form, and is situated at the extremity of Bath Street. The Hot Bath, which is about 50 yards south-west of the King's Bath, is about 56 feet square, and is remarkable for the great heat of its water, which is 117° of Fahrenheit. Besides these there are several private baths, which are not worthy of particular notice.

The bath water has a gentle chalybeate taste, which

completely disappears as soon as the water cools. The portion of iron which enters into its composition, does not exceed a grain in a gallon of water. The Bath water is also hard, and besides a little calcareous earth, and a small portion of azotic gas, it holds in solution a small quantity of silex. It contains also about $\frac{1}{6}$ of its bulk of carbonic acid. The diseases in which the Bath water is supposed to be useful, are gout, palsy, rheumatism, and diseases of the urinary organs. Bath contains 3619 houses, and 27,686 inhabitants, of whom 10,521 are males, and 17,165 females, 6103 being employed in trade. West Long. 2° 22', and North Lat. 51° 23'. See *Phil. Trans.* 1767, vol. lvii. No 22. Gibb's *Treatise on the Bath Waters*. Warner's *History of Bath*. (j)

BATH, KNIGHTS OF THE, an order of knights, so called from the ancient custom of bathing on the day previous to their installation. The origin of this order is almost as remote as that of the feudal system in Europe. It was one of the highest honorary distinctions among the ancient Franks, and was conferred, with great solemnity, as at once the reward and the pledge of extraordinary purity and virtue. Persons who were to receive this honour, were obliged to perform vigils, previous to which they underwent an ablution as emblematical of their resolution to preserve their minds pure and uncorrupted. At the same time, they came under a solemn obligation to brave any danger in the cause of virtue, and to adhere scrupulously to the belief in the Trinity, implied in their motto, *Tria juncta in uno*. It seems probable, from the discussions of some antiquarians, that this order of knighthood was introduced into England by the Saxons; and Mr Anstis has fully ascertained that William the Conqueror, and his successors, were in the practice of conferring it both in their Norman and English dominions. It can scarcely be said, however, to have been properly instituted in England till the accession of Henry IV., who, on the day of his coronation, conferred that dignity upon 46 esquires. From that time, till the reign of Charles II, it was the usual practice of the kings to create knights of the Bath at their coronation, at the inauguration of the Princes of Wales, and at the celebration either of their own nuptials, or those of any of the royal family. No fewer than 68 knights of the Bath were installed by Charles II. at his coronation; but from that time the order was discontinued, till it was revived by George I. in the year 1725. That monarch, determined to restore it in more than its former lustre, erected it into a regular military order, to consist of a grand master, and 36 companions, a succession of whom was to be regularly continued. This order was to be governed by particular statutes and ordinances, each of them impressed with a seal engraven on purpose; having upon one side the figure of the king on horseback, and clad in armour, the shield azure, three imperial crowns, or the arms ascribed to the renowned king Arthur, with the circumscription, SIGILLUM HONORATISSIMI MILITARIS ORDINIS DE BALNEO; and on the reverse, the same arms impaling the royal arms. The officers appropriated to the order, are, besides the grandmaster, a dean, genealogist, king of arms, register, secretary, usher, and messenger. The dean of the collegiate church of St Peter's, Westminster, for the time being, is, *ex officio*, dean of the order of the Bath; the other officers are appointed by the grand master, under the seal of the order.

The badge of this order is a rose, thistle, and shamrock, issuing from a sceptre between three imperial crowns, surrounded with the motto, *Tria juncta in uno*. It is of pure gold, chased and pierced, and is worn by the knight elect, pendant from a red ribbon across the right shoulder. The collar is also of gold, weighing 50 ounces troy weight, and is composed of nine imperial crowns, and eight roses, thistles, and shamrocks, issuing from a sceptre, enamelled in their proper colours, tied or linked together with 17 gold knots, enamelled white, and having the badge of the order pendant from it. The star consists of three imperial crowns of gold, surrounded by the motto upon a circle of red, with rays issuing from the silver centre forming a star, and is

embroidered on the left side of the upper garment. The installation dress is a surcoat of white satin, a mantle of crimson satin lined with white, tied at the neck with a cordon of crimson silk and gold, with gold tassels, and the star of the order is embroidered on the left shoulder; a white silk hat adorned with a standing plume of white ostrich feathers, white leather boots, edged and heeled, spurs of crimson and gold, a sword in a white leather scabbard, with cross hilts of gold. Each knight is allowed three squires, who must be gentlemen of blood, bearing coat armour. These esquires are entitled during life to all the privileges and exemptions enjoyed by the esquires of the sovereign's body, or the gentlemen of the privy chamber. (a)

BATHING.

BATHING, or the act of applying water, under various states and modifications, to the surface of the body, is a subject of such acknowledged importance, and such general interest, as to demand, in a work on miscellaneous literature, a much fuller consideration than it has usually obtained. In the present article, we shall endeavour to give as complete and popular a view of this subject, as is compatible with the nature and limits of our undertaking. We propose, first, to consider the several *varieties* of baths, and the *effects* which each produces on the human body in its natural healthy state; thence to deduce some practical conclusions and precautions on the use of bathing, in the preservation of health and the cure of disease; and to conclude with a brief historical sketch of the practice of bathing among various nations, both in ancient and modern times.

The term *bath* has, by many writers, been employed in a very extensive sense, as comprehending not only every kind of liquid in which the body can be immersed, but *air, earth, sand*, and other dry materials by which it can be surrounded. Thus, we hear of baths of *milk, whey, broth*; and if we may credit the fables of mythology, and the legends of monkish superstition, even *human blood* has been employed in this capacity. When the naked body is exposed for a considerable time to the cold air, this is termed the *air-bath*, a practice recommended by Franklin and others as a substitute for *bathing*; and when the naked body is surrounded with sand, or half buried in the earth, as has been practised on various occasions, both by regular physicians and empirics, it is said to be placed in a *sand-bath*, or an *earth-bath*. However convenient these terms may be in a medical point of view, they do not seem suited to the general purposes for which this article is intended; and we shall accordingly confine ourselves entirely to those species of bathing, in which water, under some form or other, is the agent employed.

The water of which baths are composed may be nearly pure, or it may be naturally impregnated with various mineral substances; it may be possessed of very different degrees of temperature, from near the freezing point to a heat considerably above that of the human body; and it may be applied universally to the whole

surface, or only partially to particular regions. These circumstances constitute the principal varieties of baths, which we are now to consider.

The water which flows in small rivers, brooks, or *burns*, or which fills ponds, lakes, canals, and conduits, and to which recourse is very commonly had for the purposes of bathing, may be regarded as nearly pure, since it contains but little mineral impregnation. Its action on the surface, when of a medium temperature, must therefore be little more than that of a *detergent* or cleanser. Sea water, which is so commonly used for bathing, contains, besides *sea salt*, a considerable quantity of other saline ingredients, as *muriate of magnesia*, and *sulphate of lime*, the saline matters forming more than $\frac{1}{30}$ of the whole weight. Many other mineral waters are occasionally used for bathing; as those of Bath in England, Vichy in France, and Pyrmont in Westphalia, which are chalybeate; and Harrowgate in England, Moffat in Scotland, Aix-la-Chapelle in Germany, and Barege at the foot of the Pyrenees, which are sulphureous. The effects of these baths will depend on the nature of their impregnations, and shall be considered presently.

By far the most important varieties of baths are those in respect of *temperature*; as, from the power of conducting or transmitting heat possessed by water,* and the large volume in which this element can be applied, its effect in increasing, and more especially in diminishing the temperature of the surface, and hence that of the whole body, must be considerable. Most modern writers refer the whole effects of bathing to the temperature of the bath; and though in this they perhaps generalise too much, it must be allowed, that the effects ascribed to impregnation are very trifling, when compared with those which depend on change of temperature. In this respect, baths were formerly divided into *cold* and *warm*; but since the use of the thermometer has become more general, *four* degrees of temperature have been marked in baths, and these are now distinguished into *cold, tepid* or *temperate, warm*, and *hot*.

The *cold bath* is that which possesses the ordinary temperature of the atmosphere in the temperate cli-

* We are aware that chemists are not agreed respecting the manner in which heat is transmitted through fluids; some attributing the transmission to a conducting power possessed by the fluid, while others explain it on the principle of intestine motion in the fluid, by which its particles *carry* heat to each other. This question will be examined in our article CHEMISTRY; and in the mean time we shall express ourselves on this head so as to suit either hypothesis.

mates, varying from 32° to about 65° of Fahrenheit's thermometer. Between these degrees we may estimate the temperature of most of the natural waters employed for bathing. The water of pools and small rivers, indeed, sometimes exceeds 65°; while that of the sea in this climate seldom falls below 40°, and that of most springs in this country, has generally a temperature of about 45°. It has been affirmed, that the water of springs that are inclosed for the purposes of private bathing is colder than that of open springs. We doubt whether this be a fact ascertained by actual experiment, and suspect the observation to have arisen from the fallacious circumstance of relative sensation. The principal natural springs employed for cold bathing, in this country, are those of the Malvern hills in Worcester-shire.

The *tepid* or *temperate bath* is variously defined by authors. Dr Saunders* fixes the medium temperature of what he calls the tepid bath at 90°; while Marcard† denominates a bath *cool*, when its temperature lies between 65° and 85°; and some of his commentators chuse to denominate baths within this range *tepid*. Perhaps they may more properly be called *temperate*; and the term *tepid*, which can chiefly apply only to the highest extreme of this range, might be omitted altogether. The temperate bath is usually artificial; but there are several natural springs of celebrity, which possess a temperature between 65° and 85°, and are employed as temperate, or tepid baths. Such are the springs at Matlock, Buxton, and Bristol hot wells, in England. Of these, the coolest is Matlock, whose temperature does not exceed 66°; while that of Bristol is 74°, and Buxton is as high as 82°.

The *warm bath*, according to Marcard, is that whose temperature varies from 85° to 97°; while Dr Saunders ranks under this denomination all baths whose temperature exceeds 90°. We prefer the former definition; for, as we shall shew immediately, the effects of a bath below 98° are so very different from those of baths above that temperature, as to require an accurate discrimination. We do not know any mineral spring in this country that can be said to come under the present variety, though Bristol hotwell has been remarked as high as 84°, and the Cross-bath at Bath is sometimes as low as 94°, or even 92°. On the continent there are several baths of this description, but the most celebrated is that of Pyrmont.

When baths exceed the ordinary temperature of the human body, or 98°, they are denominated *hot baths*. It is scarcely possible to assign the utmost limit of these baths in point of *heat*, as this must depend much on the sensations of the patients. An artificial hot bath seldom exceeds 105°, but the heat of some natural springs used for hot bathing is very considerable. Thus the waters of the King's bath at Bath are, at a medium, 116°; those of Vichy 120°; of Barege 122°; of Borsset, in Germany, 132°; of Aix-la-Chapelle about 140°; while those of the Caroline baths at Carlsbad, in Bohemia, are as high as 165°. The heat of the baths at

Baden, in Switzerland, is also very great; but those of Pisa, in Italy, do not exceed 104°, and are, we believe, the coolest of the natural hot baths.

The *vapour bath* is a modification of the *hot bath*, and will be considered presently.

According to the mode in which baths are employed, they are usually distinguished into *general* and *partial*; and of these there are several varieties. The term *bathing* is most strictly applicable to those cases where the whole body is plunged or immersed in the water. This is the ordinary mode of employing both the cold and warm baths; but frequently the water is thrown over the body, either from a bucket, or by means of an apparatus which causes it to descend on the head in a shower, constituting what is called the *shower-bath*. This method is by medical writers termed *affusion*, and is practised both with cold and tepid water with the best effects. See AFFUSION and MEDICINE.

When the feet are immersed in warm or tepid water, the bath employed is professionally called *pediluvium*; and when the lower half of the body is immersed in a similar bath, this is denominated *semicupium*.

The *vapour bath* may be employed either universally or partially. It consists in the application of steam, brought by pipes from a vessel of boiling water, and either admitted to the whole body, placed in a chamber for that purpose, or to any particular limb, inclosed within a proper apparatus. Sometimes this consists of a close box, made of tin-plate, communicating with a common boiler, or kettle, by means of a tin tube, proceeding from a head resembling that of a still; but, in particular cases, the box has adapted to it an air-pump, for the purpose of exhausting or rarefying the air of the vessel before or after admitting the steam. See Blegborough's *Account of the Air-pump Vapour Bath*; and *Edinburg Medical and Surgical Journal*, vol. vi. p. 315.

Having now examined the general nature of *baths*, and enumerated the most important varieties, we proceed to describe the effects which they produce on the human body, in its ordinary state of health and vigour; and to point out how these effects may be advantageously employed in the prevention or the cure of disease.

The effects of bathing will depend, partly on the quality and composition of the water employed, and partly on the quantity and mode of application; but more especially on the temperature of the bath.

Immersion, even in simple water of such a temperature as to effect the body with no striking sensation either of heat or cold,‡ is attended with several advantages. The surface of the skin is freed from that scaly *sordes*, which always collects more or less in the healthiest persons; and hence the pores of the skin are opened and relaxed, and the natural perspiration is promoted; the limbs are rendered supple, and any stiffness which may have been produced by great exertion or fatigue is removed. Such an immersion has also been found to alleviate thirst; a clear proof, in the opinion of most physiologists, that a quantity of the water is absorbed, or enters through the skin into the circulation.

* Treatise on Mineral Waters, p. 444.

† *De la Nature et l'Usage des Bains*. French Translation, p. 7.

‡ It is proper to remark, that the sensation of heat or cold, which a person may feel on immersion in water of a medium temperature, will depend on the degree of heat or cold to which his body has previously been exposed; so that a person much chilled will, on entering such a bath, feel the water *warm*, while another, who has been much heated by exercise, &c. will find it sensibly cool. This is well illustrated by the familiar experiment of immersing one hand in a vessel of very cool water, and the other in one of water that is moderately hot, and then plunging both at the same instant into tepid water. The cooled hand will feel the tepid water warm, while the heated hand will feel it cool.

If, instead of *immersion* in tepid water, affusion be employed, the general result is much the same, except that, if the body continue exposed to the air after the affusion, a sensation of coldness is produced, and this in proportion as the air is more favourable to evaporation, and, consequently, to the generation of cold on the moistened surface.

When water of the same medium temperature, but impregnated with some mineral substance, is employed, it is generally supposed, that the impregnating matters produce on the system effects similar to those which would follow their internal exhibition. That this is the case in some instances we shall not deny, but, in most cases, the effect is very trifling, and in some scarcely perceptible. Immersion in sulphureous tepid waters commonly produces an increased perspiration; and a similar use of chalybeate waters, especially if these contain any aluminous impregnation, is followed by a corrugation of the skin, and an increased action of the vessels. These effects we can readily explain, from the absorption of the sulphureous gas in the former instance, and the corrugating effect of the alum and chalybeate acting as an astringent on the skin, and thus producing pressure, and consequent contraction, or acceleration of the fluids, in the vessels near the surface; but that alkaline, or earthy salts, should produce any remarkable effect when applied in solution in the way of bathing, is not to be expected, as these salts cannot, we conceive, thus enter the absorbents of the skin. Indeed, that they are not absorbed, is evident from the circumstance, that even sea-water will allay thirst, merely by wetting with it the surface of the body. We are therefore disposed to think, that the advantages of sea-water over fresh, as a bath, used rather for health than for exercise and recreation, have been much exaggerated. In some cases, the salt may certainly act as a gentle stimulus on the surface; and this effect will be increased by heat, friction, or a long immersion; but in cases where the immersion is only momentary, or where affusion is employed, and where the body is immediately dried, salt water can have little more advantage than that of convenience.

In describing the effects and uses of baths of different temperatures, we shall begin with the cold bath, whose temperature does not exceed 65°, as that which has, in this country, been most universally employed.

When a person, in the ordinary state of health, is immersed in the cold bath, he first experiences a general sensation of cold, which is almost immediately succeeded by as general a sensation of warmth; the latter rapidly increasing, so as to cause the surrounding water to feel of an agreeable temperature. If the immersion have been sudden and momentary, and the body be immediately dried and covered from the air, the agreeable sensation of warmth continues, the whole body feels refreshed and invigorated, and, under favourable circumstances, the natural perspiration is increased. If, however, the immersion be continued for a considerable time, and the water be not near the highest range of the temperature which we have assigned to the cold bath, the sensation of warmth goes off, and is followed by numbness and shivering; the skin becomes pale and contracted; the vessels near the

surface are evidently diminished in diameter, and their contents are either lessened in volume, or propelled with greater force towards the internal parts. The person feels drowsy and inactive; his joints become rigid and inflexible; his limbs are affected with pains and cramps; his respiration becomes quick and irregular; his pulse slow and small, but for a time firm and regular; his perspiration is suppressed; and generally a copious discharge of urine takes place. If the immersion be still continued, or if the water be very cold, the pulse gradually ceases at the wrist; the action of the heart becomes weak and languid; a sensation of faintness and coldness of the stomach is experienced, followed by a rapid diminution of the whole animal heat. At length delirium and torpor come on, and the person is carried off by a fatal apoplexy.

In the above description, we suppose that the body has been suddenly plunged into the water. If, as often happens with weak or timid people, the bather enters the bath slowly, and if the water be much below 60°, the sensation of cold is more striking; a shivering is produced; and, as the person advances, so as to make the water rise towards the belly and chest, a shuddering and convulsive sobbing take place, sometimes attended with sickness and head-ache.

When the cold bath is applied by way of *affusion*, its effects are generally more sudden and more transient, though, by repeated affusions, they may be increased and prolonged to any required extent. The degree of returning warmth, in this case, will depend on the circumstance of the body's being freely exposed to the evaporating action of the air, or protected from it by proper clothing.

The increase of animal heat, which so generally follows the sensation of cold experienced on the sudden application of the cold bath, is to be ascribed to that re-action of the system, which enables it to resist an external impression by which it might be injured. This re-action is in proportion to the intensity of the cause by which it is excited, and to the vigour of the vital powers, of which it constitutes a peculiar effort. It is this re-action of the system which enables the body to derive advantage from the application of the cold bath; and, where the re-action does not take place, or takes place only in a small degree, the cold bath has been injudiciously or excessively employed.* Hence, where the system has been debilitated by long continued exertion or disease; where the temperature of the body is below the natural standard; or, where a profuse perspiration has come on, cold bathing should be avoided.

From what we have now stated, it appears that the use of the cold bath is attended with three principal effects: a sudden and powerful shock given to the body on the first application; a sudden abstraction of heat from the surface; and the re-action of the system to counteract the shock, and to restore the diminished temperature. In its general and primary effect, therefore, the cold bath acts as a powerful stimulus to the whole system, and to this effect its advantages as a remedy are chiefly to be ascribed. It has been disputed, whether, from its abstraction of heat, the cold bath can properly be considered as a stimulant; but this question, like many others in philosophy and physiology, resolves itself into a mere verbal quibble, and it is not necessary

* When, after the use of the cold bath, a person feels heavy, inactive, or chilly, or finds himself affected with headache, or tightness across the chest, it is evident that it does not agree with him, or that he has continued in it for too long a time.

that we should here discuss its merits. See Currie's *Medical Reports*, 3d edit. vol. i. p. 73.

It has been very commonly supposed, even by medical men, that immersion in the cold bath, when the body was considerably heated with exercise or other exertion, is a dangerous practice; and accordingly it is a general custom with bathers, who find themselves overheated, to wait till they are cool before they plunge into the bath. This opinion and this practice have been examined, and ably controverted, by Dr Currie of Liverpool, who has shewn, both from theory and experience, that the opinion is erroneous, and the practice injudicious. He has proved that while the body preserves a temperature above the natural standard of 98°, and the strength is not exhausted by perspiration and fatigue, the immediate use of the cold bath is not only safe, but salutary; and he was for some years in the habit of directing his infirm patients, to employ such a degree of exercise, before entering the cold bath, as might produce some increased action of the vascular system, with some increase of animal heat. See *Medical Reports*, vol. i. p. 111.

From the effects of the cold bath on the healthy body, we may deduce the following conclusions respecting its employment in the cure of disease:

The principal advantages to be expected from cold bathing, in a medical point of view, are, the reduction of excessive heat, and the producing a salutary re-action of the system. In the former way, it will prove beneficial in all those cases where the temperature of the body continues steadily above the natural standard: as in ardent fever, the hot stages of intermittents, the yellow fever of the West Indies; and in several febrile diseases, as in the early stages of scarlet fever, measles, and small-pox, so long as there is no appearance of eruption. The mode of application, in these cases, will depend on the strength of the patient; but, in general, affusion is more advisable, and more efficacious in reducing the morbid temperature, than immersion. Immediately after bathing, unless in those cases where the heat is very considerably above the natural standard, the patient should be placed in bed, and covered lightly with a blanket. In cases where the patient is much debilitated, it may be proper to defend the body by flannel, from the too violent and sudden action of the cold.

As producing a salutary re-action of the system, cold bathing has been employed with advantage in *tetanus*, or locked jaw; in those convulsions which so commonly affect young children; in insanity; and in several chronic diseases, particularly chronic rheumatism.

Cold bathing is advisable chiefly in summer and autumn, and, except in those cases where swimming has become habitual, and is borne with impunity, the time of immersion should not exceed a few minutes.

The cold bath, in all its forms, is inadmissible in all those cases where the heat of the body is less than natural; where profuse perspiration has come on; where there is any considerable degree of *plethora*, or unusual fulness of the blood-vessels; where the person is subject to inflammatory affections of the lungs, or any considerable determination of blood to the head; and where, from constitutional weakness, or unconquerable dread, the use of this powerful remedy may be productive of unpleasant feelings. Its utility in scrophula, in which it has been much employed, is at best but ambiguous.

We cannot dismiss this part of our subject without

remonstrating, in the strongest terms, against the folly and absurdity of that indiscriminate use of cold bathing which is so prevalent in this country, and which, we are convinced, is daily productive of the most pernicious consequences. If we consider the great difference that commonly exists between the summer atmosphere and the temperature of the sea, with the bleak exposed aspect of many of our watering places, and the keen winds to which the bather is often exposed, we cannot but think, that a great number of invalids, delicate females, and young and puny children, have been often materially injured in their health by an injudicious use of this powerful application. (See Saunders *On Mineral Waters*, p. 427.) We would especially caution our readers against an indiscriminate and unadvised use of the shower bath, from which we have ourselves seen and experienced ill effects.

In entering a bath of a temperature between 85° and 97°, an agreeable sensation of warmth is experienced, and this sensation is more striking in proportion as the body has been previously cooled. If, however, the water be not kept near the highest point of the warm temperature, the sense of increased heat soon diminishes, leaving only a pleasant feeling of a moderate and natural temperature. The frequency of the pulse is always diminished, and this very remarkably in those cases where, before immersion, it was preternaturally increased. This diminution of the pulse goes on during a continuance in the warm bath, though the water be preserved at nearly its original temperature; insomuch, that a natural pulse has, after immersion of an hour and a half, been reduced by nearly twenty beats in a minute. The respiration is rendered slower, and the animal heat is, in most cases, diminished. The absolute weight of the body, after immersion in the warm bath, is found to be increased, notwithstanding the perspiration which commonly takes place during immersion; and the patient feels a peculiar languor and desire of repose, though the spirits are exhilarated, and any previous irritability allayed.

It has been generally thought, that one constant effect of the warm bath is to relax and debilitate the body; and, accordingly, it has been most employed in cases of preternatural rigidity and contraction. It is an observation founded on experience, that moist, warm air produces a relaxation and debility of the living body; and hence it was natural to conclude, that the warm bath should be productive of the same effects; but the remarks and experiments of Dr Marcard seem to prove, that these preconceived opinions are founded in error. He has employed warm bathing in a great variety of cases, where the patients were either naturally of a weak habit of body, or had been debilitated by disease; and none of them experienced any debilitating effect, but, on the contrary, all of them felt stronger on the days when they used the warm bath, and most of them were restored to their former strength. In a few cases, however, relaxation and debility have followed the use of the warm bath; but these are, perhaps, to be attributed to the heat of the bath having been too great for the constitution of the patient, or the immersion having been continued too long. See Marcard *De la Nature et de l'Usage des Bains*, p. 14.

The affusion of warm water is more effectual than immersion in the warm bath in diminishing a morbid increase of temperature. It also diminishes the pulse

and respiration, and produces a tendency to sleep and repose. These effects, however, are more transient than those which follow general warm bathing.

On the whole it appears, that the stimulant effects of the warm bath are very inconsiderable; and that it is useful chiefly in allaying irritation, diminishing morbid frequency of the pulse, and relaxing and purifying the skin.

Hence the warm bath is likely to be attended with advantage in those cases of fever where the heat is preternaturally great, but where, from some affection of the lungs, or other unfavourable symptom, cold bathing is inadmissible; in the paroxysms of hectic fever; in several eruptive diseases, attended with increased heat and dryness of the skin; in most chronic eruptions of the skin, where it acts chiefly as a detergent and sudorific; in atonic gout and rheumatism, accompanied with stiffness and swelling of the joints; in chlorosis; in slight cases of palsy; in scrophulous swellings; in some spasmodic and convulsive affections, where the cold bath might prove too violent, especially in hydrophobia; in all those affections of the bowels that seem to depend on an irregular or diminished action of any part of the alimentary canal; and in cases of debility, attended with nervous irritation.

When this remedy is intended to produce increased perspiration, it is best employed in the evening, when the immersion should not be long continued, and the patient should be removed from the bath to a warm bed. Where, however, it is not intended to excite sweating, the most proper time is about two hours after breakfast. In these cases, the bathing may be protracted to twenty minutes or longer, according to the feelings of the patient; and after bathing, gentle exercise in the open air should be employed.

Those cases to which the warm bath is less applicable, are principally affections of the lungs, accompanied with great difficulty of breathing, and some organic affections of the internal parts.

The effects of the hot bath differ in several particulars from those of the warm bath. The sensation of heat experienced on entering a bath above 98° is, in general, very striking and permanent. The pulse is increased in frequency and force; the superficial veins become turgid; the face is flushed; the respiration quicker than natural, and sometimes hurried and laborious; and the perspiration is increased.* If the heat of the bath much exceed 98°, or if the immersion be continued beyond a few minutes, the determination of blood to the head is greatly increased; the arteries of the neck and temples throbb violently; a sensation of anxiety at the breast, threatening suffocation, comes on; the person grows giddy, and feels a fluttering at the heart. If these warnings of approaching danger be not attended to, the bather soon becomes insensible, and expires of apoplexy.

Water of this high temperature is scarcely ever employed in the way of affusion; nor is such an application likely to be attended with advantage, except in some paralytic affections of the limbs. In these cases it is not unusual, at Bath and other hot springs, to pump the hot water on the affected limb. By this *dry pumping*, as it is commonly called, the hot water is applied

to the affected parts under a higher temperature, than when it is drawn off into the reservoirs commonly employed for bathing.

From the above account of the effects produced by the hot bath, it appears, that this remedy is a powerful stimulus, to be employed only in a few cases where the ordinary stimuli are ineffectual. Accordingly it is very seldom resorted to in medical practice, and almost the only cases in which the general hot bath is employed are those of confirmed and obstinate palsy.

In the use of the hot bath, considerable caution is required. The patient should begin with the lowest temperature of such a bath, or about 99°, and gradually increase the heat each successive bathing, according to its effects. The time of immersion should be short; and, on coming out of the bath, great care should be taken to avoid sudden exposure to cold. In some cases, attended with fulness of habit, it may be necessary to bleed or purge before attempting the hot bath.

Though the vapour or steam bath may be regarded as a modification of the hot bath, its effects are much less violent; and it has been employed with considerable success in cases where the hot bath would be attended with danger. It therefore requires our particular consideration.

The most usual mode of employing the vapour bath is, as we have said, to expose the naked body in a room, into which the steam of hot water may be admitted. This room is generally heated to a temperature considerably above that of the atmosphere, and the body is for some time suffered to remain in this heated air; the common effect of which is to increase its temperature, and accelerate the circulation of the blood. After some time the steam is admitted, when the former symptoms are removed, and a profuse perspiration is produced. This is usually promoted by friction, and removal to a warm bed. The general effect of this process is, to relax the body, remove obstructions of the skin, alleviate pain and spasmodic contractions, and promote sleep.

In the vapour bath, the stimulant power of heat is modified and tempered by the moisture diffused through the air, and as the elastic vapour, like air, is a less powerful conductor or transmitter of heat than a watery fluid, the effect of vapour in raising the temperature of the body is much less than that of the hot bath. Its heating effect is also further diminished by the copious perspiration that ensues, so that, on all accounts, the vapour bath is safer, and in most cases more effectual, than the hot water bath.

For the topical application of steam to the greatest advantage, the air-pump vapour bath was contrived by Mr Smith; and an account of the apparatus and its effects have been published by Dr Blegborough, in a pamphlet to which we have already referred. His apparatus consists of a vessel of strong copper tinned on the inside, for inclosing the part to which the vapour is to be applied, and having attached to it a bladder, for the purpose of securing it, so as to be air-tight. To one end of the machine is fitted a pipe that communicates with a portable boiler, in which the water is heated by means of a spirit lamp. There is also a small air-pump for exhausting the machine, when the applica-

* The hot bath is described as increasing the perspiration; but this effect can take place on the *immersed* part of the body, only in the lowest degrees of the *hot* bath. The parts exposed to the air, indeed, will perspire, but the *general* perspiration can scarcely take place all after quitting the bath.

tion is to be made in rarefied air, or after it has continued for a proper time. A thermometer is adjusted to the apparatus, for shewing the temperature of the included air.

This apparatus acts on the principle of removing the pressure of the atmosphere from the part affected, while moist and heated air or vapour is applied to it. Hence, it combines the actions of dry-cupping and fomentation, each of which is occasionally employed with advantage in several morbid affections.

The cases to which this vapour bath seems best adapted, are chiefly gout, both acute and atonic; acute rheumatism, palsy, several affections of the skin, as leprosy and ulcers, and white swelling of the joints. It is also recommended in female obstructions, chilblains, tetanus, and dropsy, and has proved highly efficacious in inflammations of the stomach and bowels. The usual mode of application is, to foment the part affected, by means of the steam admitted into the body of the machine, for a time proportioned to the nature of the case, commonly from half an hour to three quarters, and then to exhaust the machine by means of the air-pump, which generally occupies another quarter of an hour.

In the employment of the general vapour bath, it is evident that its first effects would be attended with danger in a plethoric state of the body, or where there is much determination to the head. In such cases, previous steps must be taken to remove plethora, or relieve the head.

Though the external use of water, for the purposes of cleanliness and healthy exercise, must have been common among all nations, and in every age, the practice of bathing as a luxury, or a remedy, appears to indicate considerable progress towards refinement and civilization, and has been almost entirely confined to the polished nations of Europe and Asia. In the earliest records of antiquity, indeed, mention is made of bathing, either as a religious ceremony, or as the means of fortifying the body against the hardships and fatigues of war; and with these views the cold bath alone appears to have been employed.

The practice, both of general bathing and partial ablution, formed a part of the Mosaic institution; and the precepts delivered on that head were evidently intended to promote cleanliness among the people who seem to have been peculiarly subject to leprosy and other diseases of the skin. (See *Levit.* xv. &c.) Washing the hands and the feet before and after meals, was an established custom among the Jews; and we find our Saviour reproved by the Pharisees for sitting down to meat with unwashed hands. On various occasions, bathing is mentioned in the scriptures as a remedy for diseases; and it is probable that the famous pool of Bethesda, in which so many lame and diseased persons were healed, was nothing more than a natural warm bath. It is certain, that in the days of David and Solomon, the custom of bathing had become a luxury among the Jews, though it was probably never carried among that people to the

height at which we shall immediately observe it among the Greeks and Romans.*

Among the Greeks, bathing was practised, even as a luxury, before the time of Homer, or in what have been called the heroic ages. Frequent allusions are made in the works of that immortal poet to this luxury; and it appears that the baths were supplied chiefly with warm or tepid water, which in most cases was poured on the body by attendants. Thus Venus is described in the *Odyssey* as flying, after the public disgrace she had sustained in the discovery of her amour with Mars, to the groves of Paphos, where she is laved by the Graces; and the improvement produced by the bath on the native beauty of the goddess is particularly remarked. See Homer's *Odyssey*, lib. viii. v. 362.

While at the court of Alcinous, Ulysses is described as laved by attendant nymphs, and in the tenth book of the *Odyssey*, the whole process of bathing that hero, at the court of the enchantress Circe, is minutely described. (*Id.* lib. x. v. 358.) It appears from this passage, that it was usual in those early ages to anoint the body with oil or unguents, after the warm bath.

Among the Spartans, cold bathing was particularly practised; and bathing and swimming formed a part of the gymnastic exercises inculcated on the Spartan youth by the laws of Lycurgus. It is probable, however, that in later times the Spartans also employed the warm or vapour bath, as the term *laconicum*, applied to the stove used in the warm bath among the Romans, is evidently derived from *Laconia*.†

Cold bathing and swimming were practised by the Roman youth as part of their exercises in the *Campus Martius*, and the latter commonly terminated the foot race. The youthful candidates for the prize in this exercise, directed their course towards the banks of the Tiber, and after the violent exertion of running, plunged headlong into the stream. This they were accustomed to cross twice before the contention ended; and it was usual to anoint the bodies of the swimmers before the contest, a practice which would have the effect of diminishing the action of the cold. See Horace, *Od.* lib. i. ode 8. and *Satyr.* lib. ii.

In the later periods of the Roman empire, when refinement and luxury had arrived at the highest pitch, the custom of warm bathing generally prevailed among the more wealthy citizens, and the most magnificent and extensive apartments for the exercise of this luxury were constructed by the emperors and nobles. Many remains of these splendid edifices still exist, and afford us admirable specimens both of the architecture and refinement of the Romans. In the public baths there were sometimes six apartments, and seldom fewer than five. The first of these was called *apodyterium*, where the bathers undressed, and deposited their clothes, whence it was also called *spoliatorium*. In the ordinary baths this apartment was wanting. The second room in the most complete, and the first in the ordinary baths was the *frigidarium*, or apartment for the cold bath. Where

* It appears, from a remarkable passage in the second book of Kings, that the practice of bathing as a remedy for cutaneous diseases, was well understood among the nations in the neighbourhood of Judea, and that certain rivers were celebrated for their medicinal properties in this respect. Thus Naaman the Syrian, when desired by Elisha to bathe in Jordan for the cure of his leprosy, exclaims, "Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel? May I not wash in them and be clean?" 2 *Kings*, v. 12.

† Marcard appears to have been mistaken, when he speaks of *laconium* being employed by the later Greeks to signify the cold bath, as various passages in the Roman poets shew, that by the Romans, who borrowed their principal refinements from the Greeks, the word was used in the sense which we have given it in the text. See, in particular, *Martial*, lib. vi. Epig. 42.

there was no *apodyterium*, the bathers undressed in this room, whether they were to use the cold or the warm bath. The third apartment was the *tepidarium*, so called, not because it contained the warm bath, but because it was warmed to a moderate temperature, to serve as an intermediate room between the warm and cold baths, thus diminishing the danger of sudden exposure to the air, after warm bathing. In the fourth room, called *laconicum*, was placed a stove for heating the air of the room; and here those who were to use the warm bath remained for some time before immersion, and were anointed after warm bathing, or before entering the cold bath. The fifth apartment was the proper *balneum*, or warm bath, and was usually made sufficiently large to contain several bathers at the same time. It was furnished with a gallery, where those who waited for their turns in the bath might walk, and was lighted by a single window, placed immediately over, or opposite to, the *alveum*, or receptacle for the warm water. The sixth and last apartment, called *eleutherium* or *unctuarium*, seems to have formed a sort of closet for containing the oils or unguents with which the bathers were anointed. Below the building was a furnace called *hypocaust* or *suspensura*, for heating the several warm apartments, and probably the water employed in the warm bath.

These structures were called *thermæ*, and were very numerous in the capital of the Roman empire. The construction of public baths appears to have commenced under Augustus, and to have been introduced by Mæcenas, his favourite. It was soon carried to an astonishing height; and the erection of baths, where the people might be accommodated *gratis*, became an established and successful method of gaining their affections. According to Fabricius, there were in Rome not fewer than 856 public baths, some of which were sufficiently large to contain at once 1800 persons. The most celebrated of these were the baths of Caracalla, Dioclesian, and Titus, the remains of which still exist, to testify the magnificence of their founders.*

Though we have denominated the *thermæ* of the Romans *warm* baths, it appears, from many passages in Seneca and Martial, that their temperature was so high as to entitle them to the appellation of hot baths, (Mart. *Epig.* lib. iii. 25.) The use of very hot baths had become excessive during the reigns of Adrian and Severus; but about the time of Galen they had fallen into disrepute.

Bathing appears to have been an established custom, as an article both of diet and luxury, among the Asiatics at a very early period; but it became universal among the followers of Mahomet, after the promulgation of the Koran. The precepts on this head, like many others of the Arabian prophet, appear to have been borrowed from the law of Moses, and they were readily adopted from their congeniality with the manners and customs of his disciples. The Mahometans consider bathing as a necessary of life; and, besides the numerous public baths erected in their cities, and even villages, almost every family of distinction has bathing apartments within their own dwellings, for their private accommodation. These consist of two small chambers communicating with each other, and usually joined to the house by a small room in which the bathers undress. The passage

between the two chambers is secured by double doors lined with felt, inclosing between them a space where the bathers may stop, before they enter either chamber from the other. The chambers are heated by a furnace below the innermost apartment; and over this furnace is placed a caldron, that is immediately under the marble floor of the apartment, and from which proceed several pipes through the walls of the chamber, some for conveying the heated water to the bath, and others communicating with the cupola that forms the roof of the apartment. Thus the room is heated on all sides; and the heat produced is so great, that the bathers are obliged to employ high wooden sandals to preserve their feet from the burning floor. Notwithstanding this great heat, and the profuse perspiration which it occasions, the women are accustomed to pass several hours in these private baths.

The public baths are on a similar construction, though on a larger scale, and the outer apartment is generally open at the top. In this the bathers undress, gird a napkin round their loins, and put on a pair of sandals; they then enter a narrow passage, heated to a moderate degree, and extending for about twenty paces between the outer apartment and the bath. This is a spacious vaulted apartment, with a small hall next the passage, having four closets round the centre. The floor is spread with mats or cloths, on which the bathers repose, with their heads supported by small cushions; and in this position they are subjected to the heated vapour, which rises on all sides of the bath. When this begins to excite perspiration, an attendant gently presses, and, as it were, kneads every part of the body with the knuckles, turning over the body, and making all the joints crack. After this operation, the skin is rubbed all over with a piece of coarse stuff, and the bather is then conducted into a closet, and is washed or laved with perfumed lather, which finishes the bathing. After bathing, it is customary to rub over certain parts of the body a particular paste or ointment, which acts as a depilatory, for depriving those parts of hair. Savary's *Travels*, vol. i. p. 146.

The Arabians or Moors, who conquered Spain and other parts of Europe, carried with them their predilection for warm bathing; and the Moorish antiquities still existing in those countries, exhibit some excellent models of artificial baths. In particular, the palace of Alhambra in Granada, contains a magnificent bason, which might be used either for cold or warm bathing, besides smaller apartments for odorific fumigations. See ALHAMBRA.

Few of the nations of modern Europe have practised warm bathing to any considerable extent, though among all of them the cold bath has been generally employed as a favourite and healthy exercise. In the west and north of Europe, warm bathing was scarcely practised prior to the 17th century, and the custom is only gradually advancing in France and England. Within the last thirty years, artificial baths, both for cold and warm bathing, have been constructed in various parts of this island. In no part of Europe, however, are warm and hot bathing so general as in Russia and Hungary. In Russia especially, all ranks employ the luxury of what is called the sweating bath, which nearly resembles the hot baths of the East.

* For a particular account of the Roman baths, we may refer to Vitruvius, Seneca in his *Epistles*, and Pliny in his *Natural History*. An account of the Grecian baths is also furnished by Vitruvius, and by Lucian in his *Hippias*.

Various accounts have been given of the Russian baths, but we believe none is more accurate than that of Dr Sanches, first physician to the late empress Catharine, inserted in the 25th volume of the *Journal de Physique*, with which we shall conclude this article.

The baths are erected as near as possible to a plentiful supply of water and wood, these being the most necessary articles for their consumption. When the ground is marked out, two parallel trenches are dug, and lined with brick, or stone, for the purpose of carrying off the waste water. Then the walls of the bath are raised. These must be built between the two trenches; the length of each wall being about 18 English feet, and the height 10 or 11 feet. A furnace is placed within the building, supplied with wood, vaulted like an oven, and lined with stones, that become red-hot by the fire within, and thoroughly heat the air. Two or three stages are placed round the room, one above the other, three or four feet distant from the furnace; and on these lie the bathers, to receive the heat of the stone. The floor of the bath forms an inclined plane, at the bottom of which is a small pipe, for carrying off through the trenches the water that has been used. Such is the construction of the public baths, from which those of private families differ only in having better accommodations, and a chamber for the bathers to repose after bathing.

The baths are entered when the wood, with which the furnace is supplied, is nearly burnt to ashes; and the chimney is then closed, so as to render the heat of the room almost intolerable to those who are not accustomed to it. The bathers enter the room quite naked. In the private baths, some water is generally thrown upon the stones of the furnace before entering them; but, in the public baths, the common people expose themselves to the burning heat, lying on the stages where it is the most intense. The great heat at first often produces violent headache, and great thirst, to relieve which great draughts of cold water are sometimes taken, though (as Dr Sanches remarks) to the great injury of the constitution. When the room is sufficiently heated, and the warmth becomes troublesome, cold water is poured upon the hot flints around the furnace; this is instantly converted into vapour, and fills the whole room; and the water is renewed whenever the vapour begins to clear away. This excites in the bathers a most copious sweat, which they keep up by renewing the steam, and by friction of the whole body with the downy leaves of the lime tree rubbed with soap. The frictions being finished, the bathers cool themselves by pouring buckets of cold or tepid water over their bodies, or, what is more common, by plunging into a pond that is always near the bath, or, in winter, rolling in the snow. They then dress, and return to their respective occupations. The same general process is pursued in the private baths, except that there the bathers retire to the small room adjoining the bath, where they recline on beds till the sweating be over, and often sink into a profound sleep.

Cold bathing in the sea is also practised by the Russians; and the bathers here seem to pay very little regard to delicacy or decency. We are assured by Mr McGill, that, at the Russian ports on the Euxine, it is very common for males and females of all ages to bathe together in the open sea; and, deprived of all adventurous covering, to enjoy, with primitive simplicity, the pleasures of their favourite pastime. See McGill's *Travels in Turkey, &c.* vol. i.

On the subject of this article, see Floyer and Baynard on *Cold Bathing, and Hot and Cold Baths*; Marcand *Über die Natur und den Gebrauch der Bäder*, published at Hanover in 1793; or Parant's translation *De la Nature, et de l'Usage des Bains*, published at Paris in 1801; Duncan's *Medical Commentaries*, vol. xx.; Saunders' *Treatise on Mineral Waters*, chap. vi.; Currie's *Medical Reports on the Effects of Water*, 3d edit. vol. i.; and a *Treatise on Cold and Warm Bathing*, lately published at Edinburgh. See also Clarke's *Travels*, vol. i.; and Waring's *Tour to Shecrax*. (J)

BATHS. See CIVIL ARCHITECTURE.

BATHURST, ALLEN, Earl Bathurst, was born in Westminster in the year 1684. His father was Sir Benjamin Bathurst of Pauler's Perry; and his mother was Frances, daughter of Sir Allen Apsley of Apsley. Having completed his grammatical education, he was entered, at 15 years of age, in Trinity college, Oxford, of which his uncle, the celebrated Dean Bathurst, was then president. Under the direction of this eminent scholar, he acquired that elegance of taste by which he was so much distinguished; and successfully applied his mind to those more solid attainments, which are requisite to form the character of a statesman. When he was only 21 years of age, he was called to the service of his country, as member for the borough of Cirencester, which he continued to represent in two successive parliaments. He distinguished himself by his spirit and eloquence in the debates respecting the union between England and Scotland, of which measure he was a firm supporter; and was also of great service to Harley and St John, in their opposition to the Duke of Marlborough. Amidst the numerous changes, however, which were made in the public offices, after the dissolution of the Whig ministry, he accepted no place under government; but in the 10th year of Queen Anne's reign, when the administration brought 12 new lords into the Upper House in one day, he was created a peer, by the style and title of Lord Bathurst, Baron Bathurst of Battlesden.

Upon the accession of George I, when Lord Bathurst's political friends were in disgrace, his attachment remained unshaken; and he did not hesitate to lift his voice in opposition to the measures which were adopted against them, and which he regarded as most vindictive and severe. The first of his speeches mentioned in the common accounts of public transactions, was in Feb. 1717, on the bill for preventing mutiny and desertion; and, from that time, he took a distinguished part in every important measure which came before the House of Lords. He was one of the most eminent leaders, in that House, of the opposition which was made to Sir Robert Walpole; and the general tenor of his political sentiments may be made apparent, by the following short statement of the principal measures which he advocated or opposed. He strongly resisted the act for septennial parliaments in 1716, and was one of those, who entered their reasons of dissent from that bill. He was very favourable to the plans which were proposed, for relieving the scruples of the Quakers respecting oaths; and was a zealous advocate of Bishop Aterbury, in all the proceedings against that ingenious prelate. In Feb. 1730, he strenuously supported the bill, which prohibited pensioners from sitting in the House of Commons; and in May following moved an address to the king, praying for the discharge of the 12,000 Hessian troops, then in the pay of Great Britain; though he afterwards, in 1743, vindicated the propriety of continuing the Ha-

noverian troops, on account of the peculiarly critical situation of affairs at that time. He opposed the bill for reviving the salt duty, as an undue taxation upon the poor; supported the Earl of Oxlord's motion for reducing the standing army; and vindicated the utility of a national militia, as the most proper and constitutional defence in a free country. He constantly resisted all application of the sinking fund to any other purpose than the liquidation of the public debts. In the transactions which took place respecting the Spanish depredations, he bore an active part in arranging the conduct of those who were in power; and particularly exerted himself in the memorable debate upon an address to the king, for the removal of Sir Robert Walpole from his councils and presence for ever.

In 1740 Lord Bathurst was chosen a privy counsellor; and in 1757 was appointed treasurer to the Prince of Wales. Upon the accession of his present majesty in 1760, he was continued in the privy council; and, as he declined, on account of his advanced age, to accept of any public employment, he received a pension of 2000*l.* per annum. He spent the remainder of his life in dignified retirement, employing himself chiefly in agricultural improvements, and other rural relaxations. The following extract from one of his letters to Dr Swift furnishes a very pleasing picture both of his lordship's country occupations, and of his amiable disposition of mind:—"I have entered upon a new scheme of life, and am determined to look to my own affairs a little. I am now in a small farm-house in Derbyshire; and my chief business is to take care, that my agents do not impose upon my tenants. I am for letting them all good bargains that my rents may be paid, as long as any rents can be paid; and when the time comes, that there is no money, they are honest fellows, and will bring me in what corn and cattle I shall want." He had married very early in life, Catherine, the daughter and heir of Sir Peter Apsley, his maternal uncle, by whom he had four sons and five daughters; and he lived to see his eldest surviving son several years lord high chancellor of Great Britain. He retained his activity and vivacity to the last; and died after a few days illness, at his seat near Cirencester, in the 91st year of his age, on the 16th of Sept. 1775.

Earl Bathurst was considered, even by his contemporaries, as one of the most consistent and disinterested public characters of the period in which he lived; and is represented as having chosen his principles of government so happily from what was commendable in both parties, that, upon whatever side he spoke, he was never observed to lean to the extremes of either. His abilities and integrity gained him the esteem even of his political adversaries; nor was he, on the other hand, insensible to the merits of many of his opponents; but often treated them, when divested of their public offices, with so much delicacy and tenderness, as to secure their personal friendship and regard. He was distinguished in private life by humanity, politeness, and elegance of manners; and was always accessible, hospitable, and beneficent. He was intimately acquainted with the most eminent literary characters, who adorned the beginning of the 18th century; many of whom were happy to cultivate his friendship, and proud to have the honour of his correspondence. To Lord Bathurst Mr Pope addressed one of his Epistles on the use of riches; and the following lines from that poem may be given as a very good sum-

mary of his lordship's character, as well as a very sensible conclusion to this sketch of his life:

The sense to value riches, with the art
T' enjoy them, and the virtue to impart,
Not meanly nor ambitiously pursu'd,
Not sunk by sloth, nor rais'd by servitude;
To balance fortune by a just expence,
Join with economy magnificence;
With splendour, charity: with plenty, health:
Oh! teach us, Bathurst! yet unspoil'd by wealth!
That secret rare, between th' extremes to move,
Of mad good nature, and of mean self-love.

(9)

BATIS, a genus of plants, of the class Diœcia, and order Triandria. See BOTANY. (v)

BATNIANS, the inhabitants of a country in the north-east of Hindostan, bounded on the north by the Pendjab, and the river Setledge, and on the east by the district of Hurrianah, on the west by the Desert, and on the south by the Beykanecr. The territory of the Batnians is about 75 geographical miles wide from east to west, and 150 long from north to south. The cultivated part of the country extends along the banks of the Cuggur, from Futtabad to Batnir, the capital. The inundation of the country by the streams with which they are traversed occasions an uncommon fertility in the soil, and enables it to produce wheat, rice, and barley, in great quantities. The higher parts of the country produce the grain which is common throughout India; but in the other districts, where they are deprived of water, the soil is extremely barren.

Batnir, the capital of the district, and the residence of of its rajah, is about 200 miles west of Delhi, and 40 miles south of Batinda. The other cities are Arroah, Futtabad, Sirsah, and Ranyah; and these, with the numerous villages around, contain a population sufficient to furnish an army of 20,000 men, without any injury to agriculture. For some years past, however, the emigration of the Batnians to the countries west of Auhd, has considerably reduced the population. Though the territory of the Batnians is separated from the countries west of the Indus by an extensive desert, about 100 miles in length, they often venture in bodies across this trackless waste, to invade the territories which it bounds. Furnished with all the implements of war, and having their camels loaded with bread, water, and other provisions, which they deposit in different parts of the desert, they select guides, whose orders are implicitly obeyed during the journey, but who lose all their authority as soon as they reach the frontier of their enemies. In this adventurous march the guides conduct themselves by the sun during the day, and by the pole star at night; and in cloudy weather, without any of these bodies to direct them, they frequently reach the very spots where their provisions are deposited, though sometimes they lose their way, and return to the very spot from which they set out.

The Batnians are remarkably cruel and ferocious. They are robbers from their infancy; and even when they meet with no resistance, they do not scruple to murder the unhappy victims whom they plunder. The rajah himself participates in the booty of his subjects. In their expeditions to the territories of Sahib-Sing, Loh-Sing, and Bang-Sing, celebrated chiefs among the Seiks, they have generally been successful; and they have alternately laid waste the country of the Ba-

loutchians, the district of Hurriana, and the province of Beykaneer.

The Batnian women are allowed to appear in public unveiled; and, excepting those of the chiefs, they are permitted to remain in the company of the men, whose flocks they tend. The Batnians are Mahometans. They smoke tobacco to a great degree; and in all their occupations they are never seen without their hukka in their mouth. The Batnians import white cloths, sugar and cloth, and export horses, buffaloes, camels, and their superfluous rice. (a)

BATRACHOIDES, in Zoology, a genus of jugular fishes established by Lacépède to comprehend the *gradus tace* and *blennius raninus* of Linnæus. See ICHTHYOLOGY. (f)

BATRACHIA, (Fr. **BATRACIENS**.) in Zoology, an order of reptiles, established by the French naturalists, and adopted by Mr Macartney (Art. CLASSIFICATION in Rees' *Cyclopadia*.) to comprehend those tribes, which, like the frogs, have a naked body, and either two or four feet. See HERPETOLOGY; and Dumeril, *Traité Élémentaire d'Histoire Naturelle*, tom. ii. (f)

BATTA, a country in Sumatra, whose inhabitants are Anthropophagists. Mr Marsden maintains, that the Battas eat human flesh as a kind of ceremony, to shew their detestation of some particular offences, and that the practice was confined only to prisoners of war, and to persons condemned for crimes; but our ingenious countryman, Dr Leyden, who visited Sumatra in 1805, gives a very different statement. "When a man becomes infirm," he observes, "and weary of the world, he is said to invite his own children to eat him, in the season when salt and limes are cheapest. He then ascends a tree, round which his friends and offspring assemble; and as they shake the tree, join in a funeral dirge, the import of which is, "The season is come, the fruit is ripe, and it must descend." The victim descends; and those that are nearest and dearest to him deprive him of life, and devour his remains in a solemn banquet. The Battas of Sumatra have books which consist of bamboos, or the branch of a tree, upon which they write with the point of a dagger. There are nineteen letters in the Batta alphabet, which is written from bottom to top, in a way the very reverse of the Chinese. See Marsden's *Account of Sumatra*; and Leyden on the *Languages and Literature of the Indo-Chinese Nations*, in the *Asiatic Researches*, vol. x. (o)

BATTERY. See ELECTRICITY, FORTIFICATION, and GALVANISM.

BATTLE. In a military sense, a battle implies the encounter of two hostile armies, accompanied by mutual slaughter, and contending for some important object. The bad passions of men have ever been the cause of animosities and quarrels, which, among the individuals of civilized society, are generally decided according to certain laws established for the welfare of the community. But when differences arise among nations, there is no tribunal to appeal to, and the matter in dispute is often determined by force of arms. They collect a number of men together, whom they equip with the instruments of destruction, and hence form what are called armies. When these armies are brought in contact, and each endeavours to destroy the other, their efforts for that purpose constitute what is denominated a battle.

In early times, a battle was a fierce tumultuary contest, the issue of which depended upon the physical strength of the combatants, because armies were then an assemblage of men, without order or discipline. But when arts and civilization had made some progress among mankind, the military system was improved, and battles were conducted with regularity, and subjected to certain rules, that taught men to destroy their species in a more dexterous manner than formerly, or, in other words, armies were trained to the art of war, which gave them a decided superiority over an undisciplined multitude. The formation, or mode of drawing up an army in the field of battle, is an important branch of military science, as a victory or a defeat may ensue from the proper or improper disposition of the troops. It is, therefore, the business of the commander to arrange the squadrons and battalions of his army in such a manner, as to join battle with the greatest possible advantage.

The first battle, circumstantially recorded, is that of Thymbra, between the Persians and Lydians, with their respective allies, commanded by Cyrus and Cræsus. The army of the former consisted of 196,000 horse and foot, armed with cuirasses, bucklers, pikes, swords, bows, and slings, besides chariots with scythes, and moveable towers containing archers. Cyrus drew up his army in five lines, with the cavalry on the flanks. The heavy armed infantry were placed in the first line, twelve deep; in the second, the spearmen, light armed; in the third, the archers; in the fourth, troops similarly armed as the first line, intended to support the preceding lines, and as a corps-de-reserve; and in the fifth, the moveable towers. The armed chariots were divided into three small bodies, one of which was placed in front, and the other two were stationed on the flanks of the lines. Cræsus' army was twice as numerous as the Persian, and was drawn up in one line, 30 men in depth, with the exception of the Egyptian forces, which were stationed in the centre, and adhered to their accustomed order of battle. They were formed in square battalions, consisting of 10,000 men, with proper intervals between each battalion. The cavalry were stationed on the flanks of the line. When Cræsus observed that his front extended so far beyond that of the army of Cyrus, he halted the centre and advanced the flanks, that they might enclose the Persians. But Cyrus' cavalry and chariots briskly attacking them, they were dispersed. The Egyptian battalions, however, pressed forward, and drove the Persian lines up to their machines, but their flanks and rear being unprotected, they were exposed to the attacks of the victorious wings of the Persian army, and finally compelled to surrender, which terminated the battle.

The account of this battle is no where to be found, but in Xenophon's *Cyropædia*, which is a philosophical romance. But it probably bears the same relation to truth, that the incidents narrated in a modern work of that class bear to the real occurrences in life; and it may contain a faithful description of the Persian method of forming an army for battle in the age of Cyrus, with which Xenophon must have been well acquainted. We therefore discover, that by the Persian order of battle, the cavalry were placed on the flanks, and the infantry drawn up in lines, according to the nature of the weapons with which they were armed, and the efficacy that was to be expected from them in action. The first line, consisting of heavy armed troops, using the short pike

and scymitar; the second, light armed, with javelins, which they could project over the first line; the third, archers, where strong bows could throw the arrow over the two preceding lines; the fourth, heavy armed, intended as a corps-de-reserve; and, lastly, their machines and moveable towers, which answered nearly the same purpose as modern batteries.

The disposition of an army in lines is nearly all that the ancients of that and the previous ages knew of the military art regarding battles and engagements. They possessed little knowledge of the advantage of strong positions, either for attack or defence; of annoying an enemy by cutting off his supplies, or of forcing him to battle under unfavourable circumstances; of securing their flanks by marshes, rivers, or mountains; or of seizing passes and defiles, by which a small army has been often enabled to resist a greatly superior force.

The art of war was brought to considerable perfection by the Greeks, whose battles in general were conducted with science and judgment. The Athenian army, in the battle of Marathon, was drawn up in such a manner as to embrace all the advantages of local situation, so as to afford a small body every possible chance of success against vastly superior numbers. Miltiades formed his little army at the foot of a mountain, which secured his rear, and by verging towards the sea, also protected his right flank; and on his left, there was a lake or morass. His flanks were farther protected, by the trunks and branches of trees strewed on the ground, through which the Persian cavalry could not penetrate. As the Athenian army consisted of only 10,000 men, Miltiades could not sufficiently extend his front, and at the same time preserve an equal deepness in his line; he therefore weakened his centre, and strengthened his wings, on which he placed his hopes of success. The enemy bent his principal force against the Athenian centre, which, notwithstanding the efforts of Aristides and Themistocles, was compelled to give ground. But the wings of the Athenian army having broke and dispersed those of the enemy, they attacked the main body of the Persians in flank and in rear, and the Grecian spear overcoming all opposition, a total rout ensued, accompanied by an immense slaughter of the barbarians. The judicious disposition of the Athenian army in this battle compensated for the want of numbers; and being placed, from this circumstance, on an equality with the Persians, it derived all the advantages that could result from superior discipline, skill, and valour.

The battle of Leuctra, which was fought about 120 years after that of Marathon, affords a fine illustration of an able disposition in the field, and exhibits, at the same time, the progress of military knowledge among the Greeks. The Lacedemonian army consisted of 24,000 foot and 16,000 horse: and was drawn up in the form of a crescent, with the cavalry in squadrons, in front of the right wing. The Theban army was only 6000 foot and 400 cavalry in all; but it was commanded by Epaminondas. The Theban general formed his left wing into a column, fifty deep, composed of heavy armed troops, with the cavalry posted in front, and the whole was flanked by the *Sacred Band* under Pelopidas. To guard against being surrounded by the arms of the Spartan crescent, Epaminondas drew up the right wing of his army in a direction oblique to the Lacedemonian line, and diverging from it, in proportion to the extension of his ranks. The action commenced with the onset of the cavalry, and the charge of the sacred band:

which occasioned considerable confusion in the Lacedemonian ranks. Epaminondas availed himself of this favourable opportunity, and rapidly forming his column into a wedge, penetrated the right wing of the enemy, and bore down every thing before him. Victory crowned his efforts; and to the able disposition of the Theban army we must attribute his success. On his massy column he placed all his hopes, and judiciously protecting its flanks, where it was only vulnerable, by the sacred band on the one hand, and the oblique line on the other, it was irresistible. The oblique line kept the left wing of the enemy in check, and his right was flanked and attacked by the sacred band. Within a few years afterwards, the battle of Mantinæa was fought by the same general, on the same principle, and attended by similar success. The discovery of the power of a deep battalion in the form of a wedge, belongs to the genius of Epaminondas, and it gave him a decided superiority over his antagonists.

The battle of Chæronæa was decided by the power of the Macedonian phalanx; and Philip selected a place which he considered as well adapted for the operations of that body, and altogether disposed his army with great judgment and sagacity. The strength of the Macedonian army was 30,000 foot and 2,000 horse. The Greeks were nearly as numerous, but equal in courage and bravery. Philip commanded the right wing, in which the phalanx was stationed, his son Alexander the left, with the Thessalian cavalry. The Athenian forces were opposed to the Macedonian right, and the Thebans, with the sacred band, to the left. Both armies had their allies in the centre. Alexander charged the Thebans, and cut off the sacred band to a man. The Athenians repelled their opposing divisions, and the Macedonian centre gave way. Elated with their partial success, they heedlessly pursued the fugitives, and in the ardour of their impetuosity, neglected to charge the phalanx in flank, which was now unprotected, and where it was only vulnerable. Philip perceived their error, and wheeling the phalanx, rapidly gained an adjacent eminence, from which it poured down on the disordered Athenians with irresistible force, and determined the destinies of Greece.

The Grecian manner of disposing an army for battle was, by drawing it up in one front, by which the success of the day depended upon a single effort. The infantry of the Greeks consisted of two kinds of soldiers. The one heavy armed, with bucklers, lances, pikes, and scymitars; and the other, light armed, with javelins, bows, and slings. They were particularly deficient in cavalry, which is generally ascribed to the mountainous nature of the districts of Greece, where, indeed, that species of force was not so requisite as in a champaign country. The light troops were generally posted in front of the line of heavy armed infantry, for the purpose of skirmishing with the enemy; and when they had shot their arrows, and discharged their javelins, they retired through the intervals of the heavy armed troops, and forming a line in rear, continued their volleys during the action. The Lacedemonian cavalry were always placed on the extremity of the left wing, a station which they claimed as an honour and a matter of right. Of all the Grecian nations, the Lacedemonians were the most warlike, and their military system the most perfect. According to their establishment, their army was divided into battalions of four companies each, consisting of 128 men, which were subdivided in four,

or in divisions of four men in front and eight in depth, so that the battalion consisted of 512 soldiers.

The Macedonian phalanx, which produced such astonishing effects, as to be deemed almost invincible for several ages, was composed of 16,000 soldiers, heavily armed with a spear, a sword, and a shield. It was commonly divided into ten battalions of 1600 each, being 100 men in front and 16 in depth. But this arrangement was occasionally altered, according to circumstances, and the battalion was sometimes eight and at others 32 files deep. The spears of the soldiers who composed the phalanx, were 14 cubits in length, and they generally received or charged an enemy in close order. While the phalanx remained unbroken, it could not be resisted by any less compact body, but it was assailable on the flanks and rear; and if vigorously attacked on these quarters, the unwieldy pikes were only an encumbrance to the men. The phalanx required flat and level ground, as its whole force depended upon the close order of its files, which could not possibly be preserved on an irregular surface. It was only in particular situations, therefore, that it could act with effect, or produce those decisive consequences, which followed from its charge on the Athenians, at the battle of Chæronea.

In the celebrated battle between the army of Perseus king of Macedon, and that of Paulus Æmilius the Roman consul, fought near Pyænæ, the phalanx made dreadful slaughter among the Romans, and was every where irresistible, while it kept in close order, but the unevenness of the ground occasioned intervals in the ranks, which the Roman general observing, caused his soldiers to penetrate at these openings, in small bodies, and make an attack on the phalanx in flank, by which it was totally overthrown. As the whole force of the phalanx consisted in the union of its parts, which gave it weight and solidity, it was easily destroyed when divided, and Paulus Æmilius thus obtained a signal victory.

The Romans were the greatest masters of the art of war, of all the nations of antiquity; and finally prevailed over all their enemies, by their skill, bravery, and perseverance, as long as they maintained the laws and regulations connected with their military institutions. But they were occasionally worsted in battle, and the genius of Hannibal for a time eclipsed their glory.

The Roman army was usually drawn up in three lines, which were several files deep, and the legions generally possessed the centre. The right and left wings were composed of the allies, or auxiliaries, and the cavalry were sometimes stationed behind the foot, that they might pass through the intervals between the divisions, and suddenly fall upon the enemy. This form of arranging the army, however, was not invariably adhered to, for sometimes the different kinds of troops were placed in the same line. For example, when there were two legions, the one with its allies was stationed in the first line, and the other behind as a body of reserve. The Romans usually engaged with a straight front; but occasionally they varied the line of battle by advancing or withdrawing particular parts. The wings were sometimes advanced before the centre, or the reverse; and they sometimes formed themselves into the figure of a *wedge*, or into the shape of a *forceps*. But when surrounded by an enemy, they formed the *orbis*, or circular body; and when they advanced or retreated in separate divisions, the *serra*.

The *velites*, or light troops, began the battle; and

when repulsed, retreated between the intervals of the files, or by the flanks of the army, and rallied in the rear. The *hastati* then advanced, and if defeated, retired into the intervals of the ranks of the *principes*, or, if greatly fatigued, behind them. The *principes* then engaged, and if defeated also, the *triarii* then received the enemy with their ranks closed and strengthened by the *hastati* and *principes*. By this arrangement of the Roman army, the enemy had to sustain and to repulse various attacks before they could totally overcome it, and obtain a victory.

The long and destructive contest between Rome and Carthage, gave occasion to some of the most fierce and obstinate battles of antiquity, in which the valour of the troops and skill of the generals were eminently displayed. In the battle of Cannæ, the tactics of the contending parties, and of the age, are exhibited in the manœuvres and disposition of the two armies in the field. Hannibal had previously defeated the Romans in the battles of Trebia and Thrasymene; but they collected a numerous army to oppose him, which was commanded by the two consuls Paulus Æmilius and Varro. The Romans, including their allies, amounted to fourscore thousand foot, and about six thousand horse. The Carthaginian army consisted of forty thousand foot, and ten thousand cavalry. The whole infantry of the Roman army were in one line, closer and deeper than usual; the cavalry upon the two wings; and the light armed troops advanced in front at some distance from the main body. Paulus Æmilius commanded the right wing, Varro the left, and Servilius Greminus the centre of the army. Hannibal also drew up his army in one line of equal depth, with the Spanish and Gaulish cavalry on the left, and the Numidian horse on the right. The light armed troops were stationed in front, facing those of the Romans. Hanno commanded the right wing, Asdrubal the left, and Hannibal the centre of the army, which was composed of the Spanish and Gaulish legionaries, and advanced forward in such a manner, as that the whole line formed the figure of a crescent, with the convex side towards the Romans. The light armed troops commenced the battle, and the horse of the left wing of the Carthaginian army so furiously charged those of the Roman right, that they gave way and were totally dispersed. The infantry of the Carthaginian centre were unable to withstand the superior numbers of the Romans, and gave ground. Hannibal had calculated upon this circumstance, and was accordingly prepared to receive the eager Romans by a second line of battalions, which he had drawn from the wings, and were ranged in close order. The front of the Carthaginian army now became a crescent with the concave side towards the enemy, who impetuously pressed forward, exposed both his flanks to the assaults of the Carthaginian wings, and being at the same time attacked in rear by the victorious Asdrubal, who had also dispersed the cavalry of the left wing, the Romans were thus encompassed on all sides, and so much compressed, that they had not room to wield their arms and were put to the sword, to the number of seventy thousand.

Hannibal's disposition of his army in the battle of Cannæ, has been admired by the tacticians of all succeeding ages. But it is evident, that the success of the horse of his left wing gave him a decided superiority over the Romans, whose only error arose from too keenly pursuing the Carthaginian centre, while their flank

were unprotected, in consequence of the dispersion of their cavalry

In the celebrated battle of Pharsalia, the defeat of Pompey's horse gave the victory to Cæsar. Pompey drew up his army with the veteran soldiers in the centre and on the flanks; and the less expert between the wings and the main body; with the whole of his cavalry on the left flank, the right being protected by the river Enipeus. When Cæsar observed that his great antagonist had drawn all his cavalry to one point, he conjectured that Pompey intended to turn his right flank, to prevent which, he stationed six cohorts, as a separate body, behind the right wing. Pompey's horse compelled Cæsar's to give ground; but when they extended themselves with the view of flanking Cæsar's left wing, the cohorts vigorously attacked, broke, and dispersed them, and then fell upon the rear of Pompey's left wing. Cæsar in the mean time brought up his third line, which till then had not engaged, and Pompey's infantry being thus assailed on all sides, could no longer resist, but fled to their camp. Cæsar owed his success, in a great measure, in this battle to the able disposition of his army, especially in forming the cohorts, as a corps-de-reserve, which repulsed the enemy's cavalry, turned his right flank, and attacked his legions in the rear.

The Roman manner of drawing up an army for battle may be sufficiently illustrated by the instance of a single legion. The cavalry were stationed on the wings, and the infantry formed on a line with the first cohort; the second cohort drew up on the left of the first; the third occupied the centre; the fourth was next; and the fifth closed the left flank. In the second line, the sixth cohort drew up behind the first on the right flank, the seventh next, the eighth in the centre, the ninth was next, and the tenth always closed the left wing. In the rear of these two lines were the light infantry, armed with shields, javelins, swords, and missive weapons, and here also the archers and slingers were posted. In the rear of these three lines the *triarii* were stationed. They were armed with shields, cuirasses, helmets, greaves, swords, and daggers, loaded javelins, and two missive weapons. They rested on one knee during the action, that in the event of the preceding lines being defeated they might be fresh when brought up to the charge. In the beginning of the conflict, the first, second, and fourth lines, remained immovable, and the light armed troops advanced in front of the line and attacked the enemy. If they were successful, they pursued him; but if they were repulsed, they retired behind the heavy armed infantry, which now sustained the action, at first with their missive weapons, and then, sword in hand. If the enemy fled, he was pursued by the light armed troops and cavalry; but if the contrary happened, and the legion was worsted, it endeavoured to preserve its order in the retreat. A Roman legion was an army complete in all its parts, and contained every thing requisite for war within itself. A free space for his arms and motions was allowed to the soldier, and by the intervals the exhausted ranks could be easily supplied with reinforcements. The Greeks and Macedonians formed their system of tactics on very different principles; for the strength of the phalanx depended upon sixteen ranks of long pikes wedged together in the closest array. "But it was soon discovered," says Gibbon, "by reflection as well as by the

event, that the strength of the phalanx was unable to contend with the activity of the legion."

The people of antiquity were extremely addicted to superstitious rites, which preceded every great undertaking; and war, the most momentous business of mankind, called forth all their prejudices in favour of divination and sacrifices. Oracles and augurs were consulted, and lucky or unlucky days were considered, previous to entering into a war, or engaging in battle. This custom of soliciting the assistance of the gods, universally prevailed amongst the Egyptian, Assyrian, Grecian, and Roman nations. The Lacedæmonians had no share in the glorious battle of Marathon, because, by a ridiculous superstition, they were prevented from marching before the day of full moon. But so much were that people under the influence of divination, that, at the battle of Platæa, they tamely remained in their ranks while the Persians assaulted them, because their offer of sacrifice did not seem to be acceptable to the gods. Pausanias, the Spartan general, by the fervency of his prayers, obtained at last the favour of heaven; and the sacrifices appearing propitious, gave the signal for battle, when his army fell upon the Persians with such resolution that they were totally defeated.

The signals for battle among the Greeks were of two kinds, either visible or auricular. The most ancient were lighted torches, thrown from both armies by the priests of Mars, whose persons were held inviolable. The elevation of their ensigns, or flags, or a purple mantle raised upon the top of a spear, were also signals for battle. But these being laid aside, the sound of the shell and the trumpet indicated the orders of the general, and animated the souls of the brave. The Greeks then rushed into battle with a loud shout, to encourage themselves, and intimidate their enemies.

Amongst the Romans, signals were distinguished by the terms—vocal, semivocal, and mute. Vocal signals were the words given for the engagement by the general; semivocal, by the sound of the trumpet, cornet, or buccina, which directed the army whether to halt or advance, to pursue the enemy or to retreat. Mute signals, were the eagles, dragons, standards, &c. which the soldiers followed wherever they moved. The troops were accustomed to understand and to obey all these signals, whether in their quarters, or on marches, in camps, or in battles. It was also customary for bodies of troops, at a distance from each other, to convey intelligence by fires in the night, or by smoke in the day.

Before joining battle, it was the practice of the generals to address their armies; and the pages of the ancient historians are full of these harangues. They were adapted to the occasion, and calculated to impress the soldiers with the justice of their cause, or to confirm their hatred to the enemy. By such orations they were often animated with new life and courage; and sometimes retrieved their affairs, when desperate, in consequence of a seasonable appeal to their passions and patriotism. The great generals of antiquity were too well acquainted with the effect of these harangues to omit them on any important occasion; and they were followed by a shout from the soldiery, which still further stimulated their courage.

Haranguing the army, war cries, and shouts, were common to all nations; and Tacitus has preserved the speech of Galgacus to our barbarous forefathers, before they engaged Agricola's army in the battle of the Gram-

pians. In latter ages, the feudal chieftains of Scotland also observed this custom, and each clan had its peculiar *war-song*, called *sluggan*, *eloggan*, or *slughorn*, which are corruptions of the Gaelic *SLUAGH ORAN*, i. e. *the war-song*. These *slaughorans* were sometimes composed of a few words, and sometimes were of considerable length. Of the first kind is *tulloch-ard*, (i. e. the *high hill*;) which was the *war-cry* of the Mackenzies; *Lochow*, (i. e. the water of the loch,) the *war-cry* of the Campbells; and of the latter kind is the speech of Galgacus, which may have been repeated to the Romans by the Caledonian bards, who were the composers of such pieces, and therefore not altogether a fiction of the historians, as generally imagined.

The invention of gunpowder introduced a new era in the annals of war; and, from the difference of the armour of the ancients and moderns, a difference in the disposition of an army in battle necessarily resulted. The power of artillery, and even of small arms, rendered the phalanx, or deep column, totally useless, as the physical strength of men is of no avail against a ball projected by the force of gunpowder. Although the nature of the weapons now employed require a disposition in battle different from that of the most skillful captains of antiquity, yet the same principle that guided the tactics of Epaminondas and Philip has been successfully adopted by some of the most celebrated generals of modern times. To render the assault irresistible in one point, that the confusion produced there might be communicated to the whole line, was the object of the Theban hero, when he led his column in the shape of a wedge to attack the Lacedæmonians; and the phalanx of Philip of Macedon, in the battle of Chæronea, from the same cause, produced similar consequences.

Frederick of Prussia imitated and improved the tactics of these great men, and reduced their science to a practical application that corresponded with modern weapons. The attack in flank, which had been considered as only incidental, became the principal action in his battles; and to form unforeseen and skillful dispositions in the moment of onset, or during the engagement, constituted his system in the field: the principle of which is, that a greater front can be brought to act against a smaller; and thus an army, inferior in number, may surpass the enemy in exertion on these particular points, where the attack is likely to prove decisive.

Frederick's judicious disposition of his battalions, and his seizing the critical moment to attack the enemy in flank, decided the battle of Craslan; and by similar manœuvres, he defeated the Austrians in the battle of Hohenfriedberg. In the battle of Sohr, the success of his cavalry enabled the Prussian infantry to carry the Austrian batteries, and to turn and attack the flank of their army, which decided the victory. In the battle of Roshach he displayed the same manœuvres, and the same promptitude of action. The enemy's army was composed of battalions arranged alternately in column and in line; but his right flank was unsupported; and Frederick, adopting Cæsar's plan at the battle of Pharsalia, traversed his left wing with two battalions. The enemy advancing to the attack, these battalions wheeled half a circle to the right, which threw them on his flank. The French, being galled by the fire of the Prussians, pressed towards the left, which made the columns and battalions a heavy and compressed line, that was exposed to the discharges of the whole Prussian front. By this judicious disposition of Frederick's

battle, a handful of men overcame a great army. In the decisive battle of Lutzen, the disposition and manœuvres of the Prussians were exactly similar to those of the Thebans in the battle of Leuctia. Their right wing threatened to turn and attack the enemy's left, while the rest of their line formed in an oblique direction, gradually diverging as it extended. The Prussian right wing accordingly attacked and repelled the Austrian left, and, seizing an opening which it had occupied, planted a battery of cannon, that decided the fate of the day. In this battle the Austrians were 60,000 strong, and the Prussians no more than 30,000; but still the science and able disposition of Frederick reduced the superior number of the enemy to nothing, and gave him a most important victory.

The motives that may induce an experienced general to hazard a battle arise from various considerations. The consequences that may result from it, when decisive, are so important and momentous, that nothing but the fullest confidence of success, on the one hand, or imperious necessity on the other, could induce a man of reflection to venture so great a stake, especially as he must be aware that the issue depends upon so many contingencies. The greatest captains of all ages have occasionally committed errors, and miscalculated the extent of their own powers, as well as those of the enemy; but in many instances, a trivial circumstance, unexpectedly occurring, has decided a battle, contrary to all expectation. The discipline and spirit of the troops, conjoined to a confidence in the skill of their commander, are great means of ensuring success; and the expectation of victory often stimulates to extraordinary exertions.

There are certain common rules which ought to be observed by every general before he engages in battle. He ought to know the nature of the enemy's ground as well as his own; the strong or weak positions which it presents; and by what local advantages his own flanks can be supported, or those of the enemy attacked; and also to be acquainted with the weak points of his own and antagonist's disposition, that he may be prepared to strengthen the one, or to assault the other. For the purpose of supporting or attacking weak points, a *corps-de-reserve* is generally stationed in rear, and the exertions of that body have sometimes produced the most important consequences. The reserve under Desaix decided the battle of Marengo in favour of the French, by charging the Austrian centre, which had been too much weakened.

A genius for war is a peculiar gift which few men possess; and although it may be improved by study and experience, yet no man can ever be a great general, unless he be naturally active, and at the same time cool and considerate, but above all, endowed with a quickness of perception, that enables him instantly to discover every contingency that may arise amidst the bloody scene of a battle. He must be capable of opposing the sudden movements of the enemy, by new schemes instantaneously adopted, and readily executed; as it is by a general's address that he can take advantage of circumstances, and may sometimes make a motion conducive to the whole success of the battle.

The order and disposition of the troops depend entirely upon the commander, whose duty it is to give them every possible advantage; but the faithful execution of his orders depend upon his general officers, who ought to have as much knowledge of the business of

the day, as to be able to vary them according to circumstances, when in such situations as that the commander himself cannot direct their operations. The multiplicity of intricate movements that must necessarily occur in battle, and which are connected with many unforeseen circumstances, preclude the possibility of previously arranging all the different parts of an army, so as not to require, during action, the constant watchfulness of those who command; and he is the best general who is able to profit from every varying incident that may be presented to him in such a scene of bloodshed, uproar, and confusion. See Rollin's *Ancient History*, vol. ii. p. 123, 126, 132, 244, 245; vol. iii. p. 95, 99; vol. iv. p. 310, 311, 410; vol. v. p. 251; vol. vi. p. 21; vol. ix. p. 79. BATTLE, or BATTEL, a small town in the county of Sussex, which received its present name from William the Conqueror, after the decisive victory which he gained at Hastings, when he founded the magnificent abbey which still adorns this town. Battle is remarkable only for the peculiar excellence of its gunpowder, which is esteemed the best in Europe, and is known by the name of "Battle powder." Count Rumford found, that the best powder made in this place is stronger than government powder in the ratio of 4 to 3, but that it is $4\frac{1}{2}$ per cent. dearer than it ought to be. Number of houses in 1801, 291; population 2040, of whom 250 were returned as employed in trade and manufactures. (j)

BATTUECAS, the name of two uncultivated vallies in the bishoprick of Soria, in the kingdom of Leon, eight leagues from Castel Rodrigo, and fourteen from Salamanca. These vallies are scarcely a league in length, and are so completely embosomed among lofty and rugged mountains, that, in winter, the sun is only seen four hours a day. Groupes of rocks curiously shaped, excavations in the mountains, and a great variety of trees and animals, are among the curiosities of the Battuecas. A convent of barefooted Carmelites, established here in 1559, and buried among the trees of the impending rocks, is the only habitation of importance. It was long the received opinion, that these vallies were completely unknown to the Spaniards, and that they were discovered during the last century by two lovers, who had fled in search of an asylum from the vengeance of their parents. This notion, however, has been completely refuted by Father Feyjov, and also by Thomas Sanchez, who, in the year 1659, published, at Madrid, a work entitled *Verdadera Relacion y manifesto Apologético de la Antigüedad de las Battuecas*. See Bourgoing's *Travels in Spain*, chap. xxiv.; and Laborde's *View of Spain*, vol. iii. p. 353. (q)

BAVARIA, one of the circles of Germany, is bounded on the north by Franconia and Bohemia; on the east and south by the circle of Austria; and on the west by Swabia. The whole extent of this circle has been estimated at one thousand and twenty square leagues. The states which it contains, amounting to the number of twenty, are divided into two benches, ecclesiastical and secular. The first of these benches consists of the archbishopric of Salzburg, the bishoprics of Ratisbon, Passau, and Freysingen, the princely provostship

of Berckoldsgaden, and the abbeys of Saint Emeran, Nieder, and Ober-Munster, in the town of Ratisbon. The secular bench is composed of the electorate of Bavaria, the duchies of Neuburg and Salzburg, the landgraviate of Leuchtenberg, the princely county of Steinstein, the counties of Haag and of Ortenburg, the lordships of Ehrenfels, Sulzbach, Pyrbaum, Hohenwaldeck, and Breitenneck, and the imperial town of Ratisbon. The Elector of Bavaria and the Archbishop of Salzburg possess the joint power of convoking the states of this circle; and their assemblies, over which those princes alternately preside, are generally held at Ratisbon, or at Wysserburg. This circle furnishes only one assessor to the imperial chamber, though, by the treaty of Westphalia, it ought to send four.

By far the greater part of this circle belongs to the elector (now king) of Bavaria, who is one of the most powerful of the secondary princes of Germany. Before the late wars between Germany and France, his dominions in this circle consisted, 1st, Of the Duchy of Bavaria; 2d, Of the Upper Palatinate, or the Palatinate of Bavaria; 3d, Of the principalities of Neuburg and Sulzbach; 4th, Of the Landgraviate, or principality of Leuchtenberg; 5th, Of the county of Haag; 6th, Of the lordships of Ehrenfels, Salzburg, Pyrbaum, Breitenneck, and Hohenwaldeck. Besides these territories, he was sovereign lord of the greater part of the county of Erbach, in the circle of Franconia; in the circle of Swabia, he possessed the lordships of Wiesensteig, Meindelheim, and Schwabach; in the circle of the Lower Rhine, the Lower Palatinate, or the Palatinate of the Rhine; in the circle of the Upper Rhine, the principalities of Simmern, Lautern, and Veldenz, with two-thirds of the county of Spenheim, besides the reversion of the principality of the Deux Ponts, another part of the county of Spenheim, and half the bailliage of Hombourg, the other half of which belonged to the house of Nassau Saarbruck; in the circle of Westphalia, the Duchies of Juliers, and of Berg. The connection which recently took place between the families of the Elector and the Emperor of the French, induced Napoleon to erect the electorate into a kingdom, which, by the *ordonnance* of the 21st June 1808, has been divided into fifteen circles, whose names, extent, and population, are accurately laid down in the following Table:

	Names.	Extent in Sq. Miles.	Population.
1.	The circle of the Mein,	72 $\frac{1}{2}$	190,650
2.	of Pegniz,	42	141,900
3.	of the Nab,	130 $\frac{1}{2}$	220,835
4.	of Retzal,	67 $\frac{3}{4}$	190,077
5.	of the Altmuhl,	94 $\frac{1}{2}$	202,107
6.	of the Upper Danube,	79	258,589
7.	of the Lech,	91	223,176
8.	of the Regen,	121	237,095
9.	of the Lower Danube,	118	215,661
10.	of the Isar,	155 $\frac{3}{4}$	502,530
11.	of Sulzbach,	103 $\frac{1}{2}$	190,967
12.	of the Iller,	118	237,097
13.	of the Inn,	176 $\frac{1}{2}$	202,751
14.	of the Eisak,	154 $\frac{3}{4}$	191,611
15.	of the Adige,	112 $\frac{1}{4}$	226,492
Total		1636	3,231,538

The kingdom of Bavaria, which belongs to the confederation of the Rhine, has an annual revenue of 20,000,000 florins, and can bring into the field an army of 65,000 men.

At present we shall direct the attention of our readers chiefly to the **Duchy of Bavaria**. It is bounded by Tyrol and the archbishopric of Salzburg on the south; by Swabia and Franconia on the west; on the north by the Upper Palatinate; and on the east by Bohemia and Austria. Its extent is generally estimated at 576 miles, or 1600 square leagues; and the number of its inhabitants, according to the most accurate computations, amounts to about 900,000. The Duchy of Bavaria holds the fourth rank among the German states; assigning the first rank to the house of Austria, the second to the house of Brandenburg, and the third to Saxony. Under even tolerable culture, it might very easily maintain more than double of its present population; and, with the advantage of a better government, might develop a power at least four times greater than it can at present boast. It is divided into Upper and Lower Bavaria, the former of which is the extremity of the immense chain of the Alps, which stretches into this country through Salzburg and the county of Tyrol. The Duchy, including the Palatinate, is said to contain 34 towns, and 80 burghs, 8000 villages or hamlets, and thirty-six thousand estates, subject to taxation. It has 3050 churches, 548 chapels, 908 cures, 12 chapters, and 142 convents, 3765 secular clergy, and 3560 religious of both sexes. Its chief towns are Munich, Straubing, Landshut, Donawert, and Burghausen.

The southern parts of Bavaria, though very mountainous, are by no means so unfit for agriculture as they have been generally represented. Amidst those rugged and stupendous mountains, which excite ideas only of grandeur and sterility, the eye is frequently relieved by beautiful vallies, the soil of which is so rich as to repay, more than six-fold, even the awkward and unskilful culture of a Bavarian farmer. The tract of country which stretches from Munich along the banks of the Danube and the Inn, is the finest arable land in Bavaria; and is beautifully diversified with hills, which are clothed to the summits with magnificent forests. The Upper Palatinate, with that part of the Duchy of Bavaria which lies on the farther side of the Danube, is a continued chain of mountains, which ascend gradually from the Danube to Mount Fichtelberg, and the mountains of Bohemia; yet these lands afford excellent pasturage, and are, in many places, susceptible of any kind of culture. Of this country, so highly favoured by nature, a great proportion is allowed to remain altogether uncultivated. There are vast tracts of land which the indolent inhabitants condemn as marshes, but in many of which the traces of ancient furrows still remain to reproach their negligence and inactivity. There is another part of Bavaria covered with a fine forest; while a third part, without any apparent necessity, is always left in fallow. Upon the whole, it is probable, that not more than one half of the country is under proper cultivation.

There is scarcely a place in Europe where agriculture is in such a backward state as in Bavaria, or where the natural advantages of the country are so little understood and improved. Schloetzer (in his *Correspondance sur l'Agriculture de la Baviere*) informs us, that agriculture is so much neglected in Bavaria, that, except in good years, it does not produce enough of grain for the

consumption of the inhabitants. A country, placed under the same latitude with Austria, might be expected to produce wine; but Bavaria has none. Whatever wine is used there, is purchased from the neighbouring states; and the people, unlike the other southern nations of Germany, make beer their principal beverage. Another fact yet more astonishing, and which seems to indicate a very low degree of barbarism, is, that very few fruits are cultivated in this country. The neighbourhood of Munich is almost the only place where an orchard is to be found; and even there the supply of fruit is altogether inadequate to the demand of the city. Thus, while throughout the whole of Germany, even to the Baltic and the German Ocean, there is not a village where every peasant has not a well-stocked orchard,—in the south of Germany, where that species of culture would be much easier and more productive, a large country is found where the art of gardening is almost unknown. Even the rearing of vegetables is neglected: white colworts, of which they make sour crot and salad, is the only vegetable with which the Bavarian peasantry are acquainted; and although they brew an immense quantity of beer, they are obliged to import hops from other countries. In a word, they are unacquainted with every kind of industry, except that rude agriculture which has been transmitted to them from their ancestors.

The wretched state of agriculture in this country is, in a great measure, to be ascribed to the ignorance of the secular and ecclesiastical proprietors, and to the foolish administration of the officers of government. Nothing can be conceived more unfavourable to improvement than the manner in which the lands of Bavaria are farmed. The farmers are divided into four classes—The first class, who are called farmers by way of eminence, must have at least 8 work horses, and are surnamed *einsiedler*, or *hermits*, because their farms are always at some distance from any town or village. Many of these farmers have an extent of about 3 miles square, and employ from 12 to 15 plough horses: of this class there are about 40,000; the second class, called half farmers, consists of those who have only four horses; the third, called quarter farmers, of those who have only two; and the fourth class, called *haussler*, are merely day labourers, who work for the other classes, and have no horses of their own. The disparity in the condition of these different classes is attended with this deplorable evil, that it often gives to the rich farmer an opportunity of oppressing and ruining his poorer, though equally industrious, neighbour. The husbandman who has no capital, depends on his annual harvests for the supply of his immediate necessities. He is of course obliged to carry his own grain to the readiest market, and to sell it at the lowest price. The opulent farmer, on the contrary, can keep his barns filled, till an opportunity occur of selling dear; he keeps up the corn, which the less wealthy agriculturist is unable to retain, and often advances to him the whole value of his ensuing harvest. One unfavourable year involves the poor man in difficulties, and throws him entirely dependant on his rich competitor, who seizes without compassion on his property, and thus acquires new opportunities of enriching himself, and of heightening, by a dangerous monopoly, the price of provisions to the public.

This evil is still greatly increased by the injudicious mode of taxation which is followed in Bavaria. No exemption is made in favour of the poorer classes of

labourers, who are taxed, as far as their slender means extend, at the very same rate as the wealthiest of their countrymen. The veneration paid to the monks, and the prodigious number of convents established in this ill-regulated country, is another circumstance which tends greatly to retard the progress of agricultural improvement. An income exceeding one-third of the revenue of government is engrossed by these ecclesiastics, with a complete immunity from all taxation. They do more serious injury to the community, however, by persuading the richer farmers to send their sons into convents, with each of whom they receive a sum of 3000 or 4000 florins. The country, thus deprived of those who would be best able to improve it, remains only half cultivated; while the children of the other farmers, by being likewise educated in convents, are rendered totally unfit for any serious profession, or regular industry.

In a country where agriculture is so little understood, neither manufactures nor commerce can be expected to flourish. Even the manufacture of woollen cloth, which, in such a climate as that of Bavaria, is one of the most necessary articles of dress, is almost entirely neglected. More than a century ago, 7000 pieces of cloth were annually fabricated in this country, whereas, at present, it can scarcely produce 5000. Westensieder, in his description of Munich, gives an enumeration of the different tradesmen and artists there, which exhibits a very curious view of the preposterous and unnatural state of manufactures and the arts in that capital. It contains eight engravers, six chocolate makers, sixteen goldsmiths, seventeen varnishers, six bakers of gingerbread, twenty-four painters of the *corps de maître*, seventeen hairdressers; but only two basket-makers, two cloth-painters, not a single weaver, six curriers, fifteen clothiers, seventeen spinners and carders of wool, and four persons who work in cotton stuffs. There is here a manufactory of tapestry *en haute lisse*, and another in gold and silver lace; they have been anxious to establish manufactures of silk, and to rear plantations of mulberry trees, while the native productions of the country are neglected, and the use of them discouraged.

One of the chief articles of exportation from Bavaria is wood, which is floated down the rivers, and conveyed by the Danube into Hungary, where it is in great request. Tobacco, which is manufactured throughout the whole of this country, affords likewise a considerable traffic. The other articles of exportation are salt, which brings in about 286,000 florins annually; corn, of which only a very small quantity is exported; iron, rough hides, raw wool, flax, and hemp.

The mountains of Bavaria contain quarries of marble, and some of them likewise produce iron, copper, silver, and vitriol. Alum and charcoal are likewise wrought in this country; and the mines of alum, when re-opened in the year 1767, were expected to yield 400 quintals of that mineral annually. How far these expectations have been realised, we have no opportunity of learning. A few pearls are fished in the neighbourhood of Kotzing and Regen; but they do not appear to have yet attained full maturity, and have neither the water nor hardness of those from the East. Of the salt pits of Bavaria, the most remarkable are those at Reichenhall, whose source is known by the name of the *Bounty of God*. They are wrought by very curious machinery, and the value of their weekly produce is about 500 guilders.

The revenues of the electorate are of two kinds; *the*

general revenues of the country, the management of which belongs to the states; and *the electoral revenues*, which are administered by the officers of the elector. The general revenues of the country arise from a land-tax, called *there steuer*, the amount of which is regulated by the states. From this tax no portion of the landed property is exempted, whether it belong to the royal domain, to the clergy, the nobility, or to private individuals. All the estates within the duchy of Bavaria are divided into *hoffs*, or farms. The hoffs which belong to the domain, and to the nobility and clergy, are given in feu, some for life, some for two or three generations, and others in perpetuity. It is on these farms that the tax is levied. The simple steuer, or land-tax, consists of a twenty-fifth part of the net produce of each farm, a deduction being made for the feuduty paid by the farmer, and the expense of culture; but sometimes, in particular exigences, two or three of these stevers are levied in one year. The electoral revenues arise from alienation—lines, quit-rents, escheats, and other baronial rights; from the produce of the electoral breweries, and the duties imposed on the breweries of the barons and private individuals; from the duties of entry on commodities consumed in the towns and boroughs, on foreign wine and tobacco; from the customs on foreign articles of merchandise; from the salt-works; from coinage; and from the produce of the forests. The whole annual amount of the revenues of the duchy of Bavaria, and of the upper palatinate, is estimated at 12,000,000 florins.

Before proceeding to describe the government of Bavaria, it may be proper to give a short sketch of its history, tracing, as far as we are able, the successive steps by which it has arrived at its present state.

About 589 years before the Christian æra, the Boii, a people of Celtic Gaul, crossed the Rhine, and settled in Bohemia. Driven from that country by the Marcomanni, in the reign of Augustus, they withdrew into Noricum, which thenceforth received the name of *Boiaria*, or *Bajoaria*, the country of the Boii. This word was afterwards, by a slight and natural alteration, corrupted into Bavaria, the name which the country still retains. When the wide realms of the Franks were in the sixth century divided among the four sons of Clodovic, Bavaria fell under the dominion of the kings of Austrasia, and was held in vicerealty by dukes. The first of these dukes, of whom authors speak with certainty, was Gerbaud I., who lived under Clotarus, king of Austrasia. His fourth successor Theodore II. divided into four parts the large province of Bavaria. He reserved to himself Ratisbon the capital, together with Noricum and that part of the province which stretched towards the east: to Theodebert, his eldest son, he gave that part which comprehended Rhetium, the principal town of which was called Bauzanum, or *Bozen*: Grimoald, his second son, obtained the *Sundgau*, or the southern part of the province, with the town of Freysingen: the *Nordgau*, or the northern part of Bavaria, which included the town of Nuremberg, and what is now called the Upper Palatinate, fell to the share of his third son Theobald. After the death of Theodon and his youngest son, the whole province was divided between the two surviving brothers. All the northern and central parts of this territory came into the possession of Theodebert; while Grimoald obtained the southern division along with Rhetium. Theodebert was succeeded by his son Ugerberg; Ugerberg by Otilon; and Otilon by Tassilon II.,

who was the last duke of Bavaria, of the ancient family of the Agilslingians. About the year 788, Tassilon was imprisoned in the abbey of Laurisheim by Charlemagne, king of the Franks, who seized upon his duchy, and delivered the government of it to some of his counts. In the division which was afterwards made of the monarchy of the Franks among the sons of Louis I., Bavaria, with the whole of Germany, was allotted to Louis Germanicus, who took up his residence at Ratisbon. These territories being again divided by the sons of Germanicus in the year 876, Carlomannus became king of Bavaria, and was succeeded first by his brother Louis le Jeune, and afterwards by Charles le Gros, the youngest son of Carlomannus. When the states of the empire deposed Charles, and elected Arnold, the natural son of Carlomannus, as their monarch, Bavaria acknowledged the sovereignty of Arnold, and afterwards of his son Louis. In the year 920, Arnold the Margrave of Bavaria was made duke of that country by king Henry I. From that time it was successively possessed by Henry, brother of the emperor Otto the Great; by Otto II., who was deprived of it for having attempted the life of Henry IV.; by his son-in-law Guelf; and by Henry the Proud, who, in the year 1138, lost both the duchy of Bavaria and that of Saxony, in consequence of his opposition to the election of Conrad III. Though his son Henry the Lion succeeded to the possession of these domains, yet as he was placed under the ban of the empire by Charles I., he reserved only the lands of Lunenburg, Brunswick, and Nordheim.

Otto, the eldest son of the house of Wittelsbach, and lineally descended from duke Arnold, obtained the duchy of Bavaria, which was now separated from the Tyrol. His son and successor Louis was created count Palatine of the Rhine by king Frederic II., and the possession of that palatinate descended to Otto the son of Louis. Louis the Severe, and Henry, the sons of Otto, divided between them their paternal domains. Louis kept possession of the palatinate of the Rhine and Upper Bavaria; the remaining territories fell to the share of Henry. A new division was made by Louis and Rhodolphus, the sons of Louis the Severe. Rhodolphus was the founder of the house of the Electorate Palatine; and Louis of that of the Electorate of Bavaria, which continued to reign till a very recent period. Louis being elected emperor, made a treaty with his nephews, the successors of Rhodolphus, by which he formally ceded to them the palatinate of the Rhine, with the Upper Palatinate, which then for the first time received that name. The sons of Etien having made a division of Bavaria in the year 1392, formed the branches of Ingolstadt, Landshut, and Munich, the first of which branches was extinguished in 1447, and the second in 1503. Maximilian I. being invested with the electoral dignity in 1623, and with the title of Upper Palatine in 1628, obtained the confirmation of both by the treaty of Westphalia. His grandson Maximilian II. was put under the ban of the empire, but recovered possession of his dominions in 1714. Charles Albert, the son and successor of Maximilian II., being raised to the imperial throne in 1742, waged an unsuccessful war against Austria. His son Maximilian Joseph died without issue in 1777, and thus the branch of the electoral house of Bavaria became extinct; the eighth electorate, created in favour of the Counts Palatine of the Rhine, was suppressed, and these counts resumed their ancient rank

in the electoral college, with all the prerogatives which are attached to it.

Immediately after the death of Maximilian Joseph, the Elector Palatine took possession of Bavaria, and the house of Austria seized upon part of the electorate. Against this usurpation the king of Prussia made a formal appeal, and hostile preparations were immediately set on foot by both powers. The emperor levied three powerful armies, the first of which, consisting of 80,000 men, he proposed to send into Bohemia under the command of the archduke Maximilian, and general Nadasti; the second was to be commanded by the emperor in person, and by generals Lasci, Haddik, and Laudon in Silesia; and a third was to be entrusted to the command of duke Albert, and general Strowitz. The imperial army had already advanced towards the frontiers of Bohemia, when the will of the late elector of Bavaria was opened at Ratisbon. It constituted the elector Palatine universal heir, and comprehended in the inheritance the allodial estates of the late duke Clement, with the burden of maintaining constantly in Bavaria an army of 12,000 men, agreeably to the treaties of 1763, 1771, and 1774. While the elector Palatine, who had acceded to the usurpation of the emperor, was yet hesitating what part he should now take, the king of Prussia took the field, passed the frontiers of Bohemia, and encamped within view of the imperial army. Some skirmishes ensued, and all Europe was looking forward with anxiety to the event of a general engagement, when the two sovereigns, willing to spare the blood of their troops, entered into a negotiation. Next year the house of Austria declared itself willing to renounce part of its pretensions, and to sign an accommodation; Prussia was satisfied, and all thoughts of war were for the time relinquished. The future history of Bavaria will come more properly under that of Germany, with which it is closely, and indeed inseparably, interwoven. We may only observe, that the jealousy which has long subsisted between the houses of Bavaria and Austria induced the former to remain neuter in the late war between Germany and France. This circumstance naturally conciliated to Bavaria the favour of the French; and when Austria peremptorily demanded an army from the elector, Bonaparte took him under his protection, adopted him as an ally, and at length conferred upon him the dignity of royalty.

The elector of Bavaria held the fifth rank in the electoral college, and the second among the secular electors. As duke of Bavaria, he ranked first in the college of the princes of the empire, and had the privilege of first delivering his opinion. The house of Bavaria had likewise been from a very remote period in the hereditary possession of the office of arch-seneschal of the empire. By the act of division passed between Louis, duke of Bavaria, and his nephews, in the year 1329, it was agreed that the dignity of arch-seneschal should be common to the houses of Bavaria and Palatine, but that the right of voting in the electoral college should belong to them alternately. The Palatine house being privately invested by the golden bull with the dignity of elector, afterwards appropriated to itself the office of arch-seneschal. But when the elector Palatine Frederic was put under the ban of the empire in 1623, both of these dignities reverted to the duke of Bavaria. The first was confirmed to him by the treaty of Westphalia, but the latter was not mentioned, and was enjoyed by the elec-

tor Palatine from 1705 to 1714. The vicariate of the empire on the Rhine, in Swabia and Franconia, being connected with the office of arch-seneschal, occasioned a very warm contest between the two electors. At first it was agreed that the vicariate should be exercised by both houses at once; but it was afterwards resolved that they should enjoy it alternately, and this resolution was approved of by the college of electors, and confirmed by the emperor in 1752.

The elector Palatine succeeded to all the rights and dignities of the former electors of Bavaria, and left the laws and government of the country nearly in the same state in which he found them. The states of Bavaria are composed of three orders, prelates, nobility, and people. In the assembly of the states, the nobility have one half of the suffrages, the other half is divided between the clergy and people: thus, when there are four prelates and four deputies from the towns, there are eight noblemen. The duchy is divided into four generalities or governments; viz. the governments of Munich, Straubing, Landshut, and Burghausen. Each government sends two noblemen, a prelate, and a deputy for the towns, to the assembly of the states. In every generality a prelate is charged with the collection of the taxes paid by the clergy, and two noblemen receive those due by the nobility; the magistrates of towns receive the contributions of individuals. The hereditary officers of the elector are, the governor of the hereditary countries, the steward, marshal, cup-bearer, and huntsman.

The Bavarians are, in general, robust, corpulent, and muscular; yet in almost every particular the very reverse of handsome. So grotesque, indeed, is their appearance, if we may believe Baron Reisbach, that many of them resemble caricatures rather than real figures of men. Their head is round and thick, their neck short, their shoulders narrow, their paunch broad and prominent, and their legs short and chubby. Their pace is heavy and slow, and their little eyes peeping through their swollen eye-brows, are sufficiently expressive of their inherent knavery. The beauty of the Bavarian women forms a strange and pleasing contrast to the shapeless clumsiness of the men. Their form appears the work of the graces; their complexion outvies the finest caricatures, and baffles the imitation of the ablest painters; while the fascination of these charms is completed by the vivacity and grace of their manners.

The Roman catholic religion is established in Bavaria in its worst form. Its numerous convents swarm with ecclesiastics of different orders, whose mutual hatred has often distracted the state with civil dissensions; while their influence over the people serves only to spread the contagion of those vices which disgrace their character. At no very distant period one half of the inhabitants of Bavaria were protestants, and several public regulations were made for their security. But, through the intrigues of the Jesuits, they were exposed to every kind of oppression, and the court swayed by the interested suggestions of these ecclesiastics, endeavoured to root them out as pernicious weeds to the state. These persecutions compelled the protestants to abandon their country; they emigrated to one of the wildest deserts in North America, and a great portion of Bavaria was left completely desolate.

The licentiousness of Bavarian morals is almost incredible: and seems chiefly to proceed from the indo-

lence and bigotry which are characteristic of the nation. Neither order nor good morals can be expected to prevail among a people who prefer mendicity to the slightest exertion; who are influenced by no higher principle than a blind submission to priests, infamous and profligate as themselves: and whose basest crimes are expiated by a very trifling fine. The negligence, the selfishness, and the folly of those in power, tend greatly to increase the evil. In Munich alone there are not fewer than four thousand men maintained in idleness at the expense of the court. These men, in general uneducated and unprincipled, have no relish for any rational employment or recreation; their whole time is spent in gaming and debauchery; the rest of the inhabitants are infected by their example; the contagion spreads throughout the country; and the licentiousness becomes general and extreme. Such, indeed, is the universal depravity of morals in this country, that a Gascon officer remarked, with no less justice than severity, that Bavaria is the largest brothel in the world.

From this prevailing corruption, religion and virtue find no asylum. Even churches and universities, which ought ever to be their inviolable sanctuaries, are not free from the encroachments of profanity and vice. The ecclesiastics are no less licentious and indecent than the rest of the people; inns and disorderly houses are to be found in the neighbourhood of every church; and even the sanctuary itself has sometimes been made the scene of the most abominable crimes. Students, too, who repair to the universities with the professed intention of improving in learning and virtue, are in general initiated in the grossest brutality. It is expected, as the indispensable qualifications of every student in the university of Ingolstadt, that he be provided with a thick bludgeon, and wear a helmet; that he be able to swallow eight or ten quarts of beer at a time; and be ready at all times, and on any pretext, to fight with the officers of the garrison. Such shocking irregularities have, of necessity, lowered the reputation of the university; and, in spite of the zeal and ability of the professors, and the annual edicts of government, prohibiting a Bavarian from studying out of his native country, the number of its students is constantly diminishing.

The peasantry of Bavaria, though perhaps less licentious than the citizens, are yet more brutal and disgusting. Coarse, slovenly, and dissolute, they are ignorant of all the comforts of civilized life, and are raised but very little above the level of the rudest barbarians. A savage ferocity mingles with their superstition, and often gives rise to scenes of blood. They value a festival, or public entertainment, according to the fierceness of the quarrels by which it has been distinguished, and the number of the combatants who have been killed. This ferocity of disposition is connected with much personal intrepidity. Towards the end of the 17th century, the Bavarians were accounted the best soldiers in Germany. But they are now so impatient of order and discipline, that they deserve not the name of soldiers, and are of no use in an army, except to ravage a hostile country; yet, irregular and undisciplined as they are, they often exhibit the most amazing efforts of courage, and, rather than recede one inch, will fight to the last extremity.

The military force of Bavaria, including the palatinate, amounts to about 12,600 men.

BAUTZEN. See **BUDISSEN**.

BAY OF ISLANDS, a bay on the east coast of New Zealand, remarkable for the number of islands which embroider its shores. It affords good anchorage, and refreshments of every kind. W. Long. 185° 38', S. Lat. 35° 18'. See Captain Cook's *Voyages*; and **NEW ZEALAND**. (j)

BAXTER, RICHARD, an eminent divine, was born at Rowton, in Shropshire, November 12, 1615. He was carefully instructed by his father in the principles of Christian piety, and gave early indications of a devout and studious disposition. He was less fortunate in his opportunities of literary improvement, and his first teachers were neither men of great learning nor of good morals. He made very considerable attainments, however, under Mr Owen, master of the free school at Wroxeter, who taught him the elements of grammar; under Mr Wickstead, chaplain to the council at Ludlow, who allowed him the use of an excellent library; and under Mr Garbett, minister of Wroxeter, who carried him through a course of philosophy, and greatly encouraged him in the pursuit of his studies. In 1633 he was persuaded to seek employment at court; and he went to Whitehall, with recommendation to Sir Henry Herbert, master of the revels; but being soon disgusted with that mode of life, and having a strong predilection for the clerical office, he returned home, after little more than a month's absence, and resumed his former studies with redoubled vigour. In the mean time he was appointed master of the free school at Dudley; but his bodily health became so infirm, that, from the 21st to the 23d year of his age, he lived in the constant expectation of death, and was so deeply impressed by a sense of the importance of religion, that he became still more anxious to employ his remaining strength in recommending the subject to his fellow creatures. In 1638 he received orders from Dr Thornborough, bishop of Worcester, and preached frequently at Dudley and the neighbouring villages, with great satisfaction to his hearers. Within less than a year after his ordination he went to associate as assistant to Mr Madstard, at Bridgnorth; and in 1640 he was invited to the office of stated preacher at Kidderminster. Here he employed himself with unwearied diligence in the instruction of his parish, and produced a very remarkable reformation of manners among a very dissolute people. When the civil war commenced, about two years afterwards, he joined with the parliament, and was exposed to several inconveniences on that account. He was obliged to remove his residence, first to Worcester, then to Gloucester, then back to Kidderminster, and then at length to Coventry, where he continued about two years, residing chiefly in the governor's house, preaching both to the soldiers of the garrison

and to the people of the town, and exerting himself, with great success and zeal, in repressing the anabaptists, and restraining the violence of the other sectaries. With the view of preventing, still more effectually, the growing influence of turbulent men, he connected himself with the army, and acted for a considerable time as chaplain to the regiment of Colonel Whalley. In 1647 he was reduced to such a feeble state of health, by a frequent bleeding at the nose, that he was obliged to relinquish his employment in the army, and, after remaining some time at the house of Sir Thomas Rouse, he returned to his ministry at Kidderminster. He openly opposed many of the revolutionary measures which now began to prevail; discouraged the taking of the covenant; dissuaded the army from resisting Charles II. at the head of the Scots; expressed his dissatisfaction with Cromwell's usurpation; recommended loyalty to their prince, in a discourse before the parliament; preached a thanksgiving sermon at St. Paul's, on account of General Monk's success; after the restoration was appointed one of the king's chaplains in ordinary, and was always treated by him with peculiar respect. He frequently waited upon the king, in order to procure, by his means, more favourable terms for the non-conformists; was one of the commissioners at the Savoy conferences on the same subject; and was employed to draw up the *reformed liturgy*. He declined the bishopric of Hereford, which was offered to him by Lord Chancellor Clarendon, and desired nothing so much as to resume his humble labours at Kidderminster; but he was so obnoxious to the high-church party, that all the favour of the chancellor could not procure his settlement there, in the way that he approved. He preached occasionally in the neighbourhood of London, till the passing of the act against conventicles in 1662. About this time he married the daughter of Francis Charleton, Esq. a distinguished magistrate in Shropshire, and lived very quietly, first at Acton in Middlesex, and afterwards at Totteridge, near Barnet. During this retirement, he received various tokens of the royal favour; was consulted upon the plans for settling the ecclesiastical disputes in Scotland; and was offered his choice of preferments in that country. He was one of the principal sufferers in the oppressive severities which were exercised against the non-conformists, during the reigns of Charles II., and his successor James II. He was repeatedly imprisoned, even when he was labouring under the pressure of sickness, and was frequently sentenced to pay very heavy penalties. But nothing could deter him from discharging his ministerial functions, when proper opportunities were presented; and, even when confined to his chamber by increasing infirmities, he continued to expound the Scriptures to all who chose to assemble together at his seasons of family devotion. He bore his last illness with the most exemplary resignation, and benefitted his numerous visitors by his good instructions and example. When constrained, by the extremity of his pains, to wish for death, he used to check himself, and say, "It is not fit for me to prescribe; when thou wilt, what thou wilt, how thou wilt." He died at the age of 76 years, on the 8th of December 1691, and his body was accompanied to the grave by many persons of all ranks and denominations.

The person of Mr Baxter was tall, slender, and stooping; his countenance grave and composed, somewhat inclining to a smile; his eye piercing, his speech articulate, and his deportment plain. His constitution was

weak and sickly through the whole of his life; yet, by the united influence of temperance and industry, he was able to undergo a most extraordinary degree of labour, both in writing and in preaching. He expressed himself in conversation with great propriety and ease; was remarkable for his intrepidity and composure on all occasions; and hence it was very strongly remarked of him, by a learned opponent, that "he could say what he would, and could prove what he said." Both in his political and theological character, he was always friendly to conciliatory measures; and hence he has been reviled by the violent, but respected by the temperate, of all parties. His sentiments of moderation, however, were not the result of a feeble or fearful mind; and, while he was anxious to reconcile, he was not afraid to resist. He laboured to promote universal charity and peace, at a period when it was accounted a crime not to be fierce in support of some sect or other; but, at the same time, as was said of him by Mr Boyle, "he feared no man's displeasure, nor hoped for any man's preferment." He boldly opposed the progress of revolutionary proceedings, and of Antinomian errors; and the severities to which he was subjected, in the latter part of his life, were not owing to any suspicion of his disaffection to government, but to his upright avowal of non-conformist principles. As a complete refutation of the calumnious charges of sedition and rebellion which have been brought against him, it is sufficient to mention the many eminent characters, both in church and state, whose patronage and intimacy he enjoyed to the last; such as the earl of Lauderdale, the earl of Balcarras, chief justice Matthew Hales, alderman Ashurst, sir John Maynard, sir James Langham, sir Edward Harley, archbishop Tillotson, &c. He was, in short, a man of the greatest zeal in religion, without any tendency to faction or fanaticism; and possessed the greatest simplicity of manners, with the utmost firmness of mind and uniformity of character.

With respect to the literary attainments of Baxter, he says of himself, that, except the Latin, Greek, and a slight acquaintance with the Hebrew, he had no great skill in languages; that he had no taste whatever for the mathematics; but that he was particularly attached to the study of logic, metaphysics, pneumatology, and the divinity of the schools. He was more desirous to have the knowledge of *things* than of *words*, and he possessed a great share of solid learning. His works were so very voluminous, that it is not yet ascertained what was the precise number of his writings; but he is known to have composed more than 145 distinct treatises; of which four were folios, 73 quartos, 19 12mos and 24mos, besides single sheets, separate sermons, and a variety of prefaces to the publications of other authors. A particular account of his writings may be seen in the *Biog. Britan.* Notes P and X; and in Calamy's *Life of Baxter*, vol. i. p. 691. The most useful of his productions are, his *Catholic Theology*; which was intended to compose the disputes between the Calvinists and Arminians;—his *Reformed Pastor*; which has been highly esteemed by many eminent divines;—his *Call to the Unconverted*; of which 20,000 copies were sold in one year; which was translated into most of the European languages; and of which Dr Watts has said, that he would rather be the author than of Milton's *Paradise Lost*;—his *Christian Directory, or Body of Practical Divinity*; *Everlasting Rest*; *Dying Thoughts*; *Poor Man's Family Book*; *Paraphrase on the New Testament*; *Converge with God*

in Solitude; and *Narrative of his own Life and Times*. The most of his practical pieces have been published in four volumes folio; judicious abridgments of the best of them have been made by Mr Fawcett; and a new edition of them all is now carrying on, which is expected to be completed in 16 vols. 8vo, one of which will contain a portrait of the author, with a history of his life and times.

The works of Baxter, like their author during his life, have been very variously estimated; but they are highly commended by the most competent and unprejudiced judges. "He cultivated every subject," says bishop Wilkins, "that he handled." "His practical writings were never mended," says Dr Barrow, "and his controversial ones seldom refuted." "I cannot but commend," says bishop Gaudens, "the learning, candour, and ingenuity of Mr Baxter." "I cannot forbear looking upon him," says Dr Doddridge, "as one of the greatest orators, both with regard to copiousness, acuteness, and energy, that our nation hath produced." "As an useful writer, as well as a successful controversialist," says Dr Adam Clarke, "Mr Baxter has deservedly ranked in the highest order of the divines of the 17th century. His works have done more to improve the understanding and mend the hearts of his countrymen, than those of any other writer of his age. While the English language remains, and scriptural Christianity and piety to God are regarded, his works will not cease to be read and prized by the wise and pious of every denomination." And, when Mr Boswell inquired of Dr Johnson, which of Baxter's works he should peruse. "read any of them," was the reply; "they are all good." He is indeed generally prolix, and often metaphysical; but such was the taste of the times in which he lived; and his writings are certainly distinguished by amplitude of thought, vivacity of imagination, strong and clear good sense, fervent devotion, and pathetic address. See *Biog. Britannica. Gen. Biography. Calamy's Life of Baxter. Silvester's Life of Baxter. Baxter's Narrative of his own Life and Times.* (g)

BAYEN, PETER, a celebrated French chemist, and member of the National Institute of France, was born at Chalons in the year 1725. His early propensity to study induced his friends to send him to the college of Troyes, where he went through a regular course of study, and imbibed a taste for natural philosophy. Anxious to improve his knowledge of chemistry, to which he was particularly attached, he went to Paris in 1749, and studied pharmacy under an able apothecary, the father of the celebrated Charas. The diligence and thirst for knowledge displayed by Bayen attracted the notice of his master, who gave him every opportunity of improvement, and entrusted him with the direction of his laboratory. From the skill which he had acquired in pharmaceutical operations, he was appointed chief apothecary to the army in Germany, during the seven years war, before he had reached his 30th year.

Upon his return to Paris, at the conclusion of the war, he was employed by government to analyse all the mineral waters in France. This labour, at first performed in conjunction with Venel, afterwards devolved upon Bayen alone, who published several works upon this important subject. His analysis of the waters of Baresges and Bagneres de Luchon is particularly valuable, and is an admirable model for all similar researches.

The funds which were destined for these interesting investigations having been diverted to other purposes,

Bayen abandoned the Pyrenees, and employed himself in the analysis of various specimens of minerals which he had collected in his travels. The results of these analyses were published in the *Memoires des Savans étrangers*, in numerous memoirs on marbles, granites, serpentines, porphyries, jaspers, schists, and iron spar.

Bayen had the high honour of being the first who doubted the existence of the phlogistic principle of Stahl. He at first communicated his doubts to several of his friends, but particularly to the celebrated Macquer, who did not approve of them. Without being discouraged at the opinion of Macquer, Bayen continued his researches, and proved, that the excess of weight, the colour, &c. of all metallic oxides, were owing to the absorption of one of the constituent parts of atmospheric air.

The illustrious Lavoisier, who was then occupied with the subject of metallic oxides, happened to be present when the memoir of Bayen was read in the academy; and, struck with the importance of the discovery, he repeated all the experiments, and was thus led to those great views by which he effected a revolution in the science of chemistry.

Bayen discovered the singular property of fulminating, which several metallic oxydes possess, when mixed with a small quantity of sulphur. He also found, after long and difficult investigations, that tin, in its pure state, contained a very small portion of arsenic; which, however, did not render it unfit for the purposes of civil life. He found also, that the tin of commerce, which was wrought by pewterers, contained copper and antimony, by which it was hardened; zinc, by which it was whitened, bismuth, which rendered it sonorous; and lead, which diminished its value.

Exhausted with these labours, and worn out with domestic misfortunes, Bayen died in the beginning of 1793, in the 72d year of his age. See Lassus *Notice sur la vie et les Ouvrages du M. Bayen*, in the *M-m. Nat. Instit.* (π)

BAYER, JOHN, a German astronomer and lawyer, who flourished about the end of the 16th and beginning of the 17th centuries, and who is celebrated as the author of the first celestial atlas of any importance, and of a valuable improvement in the nomenclature of the stars, which has been adopted by the astronomers of all nations. This improvement, which consisted in denoting the stars of each constellation by the letters of the Greek alphabet, was published in 1603, in his *Uranometria, sive omnium asterismorum schemata quinquaginta et unum in totidem tabulis nova methodo delineata*. August Vindelic. Fol. 1603. The second edition of this work was published at Ulm in 1648; the third in 1654; and the fourth in 1661.

The atlas of Bayer was published in a new form in 1627, under the title of *Calum Stellatum Christianum*, by Julius Schiller of Augsburgh, who removed the names of the constellation that were drawn from the fables of the Greeks, with the pious intention of promoting to that high distinction, the figures and the names of the sacred scriptures. He placed the twelve apostles in the twelve signs of the zodiac, the New Testament in the northern hemisphere, and the Old Testament in the southern hemisphere.

This new scheme, however, did not succeed according to the pious wishes of its author, and the heathen names of the constellations were accordingly retained in all the subsequent editions of the *Uranometria*.

About thirty-five years afterwards, in the year 1662, Philip Cœsius, a Dutchman, proposed a similar innovation. He made the constellation of the Ron, that which Abraham sacrificed for his son Isaac. He made the Bull, that which was sacrificed by Adam: The Twins were Jacob and Esau, the children of Rebecca, &c. See ASTRONOMY, part i. book iii. chap. i. See also Weideler's *Historia Astronomiæ*, pp. 458, 596. Montucla's *Hist. des Mathemat.* tom. ii. p. 251. Bailly, *Hist. d' Astron. Moderne*, tom. ii. p. 150. (o)

BAYEUX, the *Beducussum* and *Baiocæ*, of the ancients, is a town of France, in the department of Calvados, situated on the river Aure. It contains a magnificent cathedral with three towers; seventeen parishes; seven convents; two priories; two hospitals; and a castle. Bayeux was long celebrated for the famous piece of tapestry executed by Matilda, the wife of William the Conqueror, and representing the history of the conquest of England. It was a linen web, about 442 feet long, and two feet broad. Engravings of this curious piece of workmanship, which have been lately transported to Paris, may be seen in Montfaucon's *Antiq. Expliq.* tom. i. and ii., and Ducarel's *Anglo-Norman Antiquities*. Bayeux carries on a considerable trade in leather. Population 9970. West Long 42° 51', North Lat. 49° 16' 30'. (q)

BAYJAH, BAIA, or BEJA, the *Tacca, Tagense*, and *Baga*, of the ancients, is a town of Africa, of great trade, in the kingdom of Tunis, situated on the declivity of a hill on the small river Wedel Boule. All the grain from the fertile plains of Busdera is brought to this town, from which it is carried to the different parts of the kingdom. A public fair is held here, to which the wandering Arabs resort with their flocks and manufactures. A citadel of no strength is situated on the summit of the hill; and the ancient walls, with a few inscriptions, are still to be seen. East Long. 9° 25', North Lat. 36° 42'. See Shaw's *Travels*, p. 92. (j)

BAYLE, PETER, was born at Carla, in the county of Foix, in the year 1647. He discovered, from his infancy, great intellectual talents, an insatiable thirst for learning, and uncommon powers of study and application. His father, who was protestant minister of Carla, and who seems to have been both a wise and a good man, instructed him with great care in the Greek and Latin languages; but finding that the task of education occupied more time than he could spare from the duties of his pastoral office, and that his son was capable of much higher attainments than he could possibly reach, under his tuition, he sent him to the academy of Puylaurens. Young Bayle arrived there in his 19th year; and his passion for letters continued so strong, that, to gratify it, he spent, in preparing his academical exercises, and in reading such books as he could procure, those hours which his fellow-students devoted to amusement or to pleasure; and, indeed, applied so closely to his studies, that he repeatedly fell into severe and dangerous distempers.

From Puylaurens he went to Toulouse, one of the most celebrated universities in France, where he obtained great reputation by his good conduct and literary acquirements. He had not been long there when he changed his religion, and became Roman Catholic. This step displeased his father so much, that the paternal aid, on which he was still dependent, was withdrawn, and he was under the necessity of accepting money and protection from Mertier, bishop of Rieux.

Actuated by the zeal of a new convert, and in obedience to the commands of his new patron, he wrote a long letter to his brother, with a view to persuade him and the rest of the family to embrace the Catholic system. This letter, filled with those common-place sophisms which had strangely seduced his own mind, and somewhat tinctured with the spirit of gloomy fanaticism, failed to produce its intended effect. And indeed, many months had not elapsed, when he himself returned again to the bosom of the Protestant church. The doctrine of implicit faith did not accord with his intellectual habits. He considered examination in religious matters to be an indispensable duty. He continued to think, to inquire, and to compare. His researches were assisted by the conversation of two gentlemen of wit and address, who were anxious for his conversion. And the result was, that, convinced of his errors, he departed secretly from Toulouse, to avoid the resentment of the Jesuits, was reconciled to his family and friends, abjured the Popish communion, in presence of several ministers, and immediately set out for Geneva to resume the course of his studies. There he soon distinguished himself: and got acquainted with M. Basnage, and other learned men, to whom he endeared himself by his talents and his virtues. He refused a regency in the college; but accepted of the office of tutor to the Count de Dhona's children. Shortly after he became tutor to a merchant's son in the neighbourhood of Rouen. But disliking the solitary and sequestered life to which he was doomed in both these places, he resolved to go to Paris, where he expected to meet with every thing agreeable to his taste. Soon after his arrival (1675) he became preceptor to the children of a Mr de Beringhen. This situation, however, did not please him more than those which he had left on account of their tiresome solitude. The character of a preceptor, as he remarked in a letter to Mr Basnage, had sunk so low in the general estimation, that no personal merit almost could redeem it from contempt. And he was desirous, therefore, of getting into some respectable and permanent establishment. His wishes were soon gratified. By the friendly exertions of Mr Basnage, and by the superior merit which he himself displayed in a comparative trial, he was appointed a professor of philosophy in the academy at Sedan. He remained there for about six years, fully justifying the good opinion which had been entertained of him by his friends, and gaining the respect and esteem even of those who had been his keenest opponents. When the Academies of the reformed were suppressed in France, that of Sedan was the first that suffered (1681) although its continuance was an express stipulation in the treaty, made between the Duke de Bouillon and Louis XIII. and afterwards confirmed by Louis XIV. himself.

By this most iniquitous measure, Mr Bayle was thrown out of regular employment. But in the course of a few months, he and Jurieu were nominated professors in a school that was instituted on their account in the town of Rotterdam. It was here that he commenced his labours as an author, by publishing a Letter on Comets, as presages of evil, which he had written in consequence of the appearance of the famous comet of 1680, and had originally intended to print at Paris. It was printed at Cologne in 1682, under the title of *Lettre à Mr L. A. D. C. Docteur de Sorbonne. Ou il est prouvé, par plusieurs raisons tirées de la Philosophie et de la Théologie, que les Comètes ne sont point le presage d'*

aucun malheur, &c. He did not put his name to it, and employed other methods to prevent the public from suspecting it to have proceeded from his pen. But some of his friends, to whom the secret had been communicated, thinking the concealment of it a piece of injustice to his reputation, told openly that Mr Bayle was the author. His next work, which came out in the same year, was entitled, *Critique Generale de l'histoire du Calvinisme de M. Maimbourg*. It was a duodecimo volume of 339 pages closely printed; yet such was the facility in writing which he had acquired, that he finished it in the space of fifteen days. This treatise, in the form of a series of letters, contained general observations on Maimbourg's work, pointing out its errors and its malice, and exhibiting such a happy mixture of raillery and good sense, as could not fail to mortify the feelings and sink the credit of the author, against whom it was directed. So acceptable, indeed, was it to the reformed, whose cause it vindicated, and so agreeable to the more judicious and moderate of the Catholics themselves, that the first impression was sold off almost as soon as it appeared. A great many copies of it found their way into France, where it was well received, and much read. Maimbourg, provoked at its popularity, and under the dominion of that persecuting spirit, which he had manifested in his book, applied to the king, for an order to suppress the obnoxious publication. A king, who could set his seal to such a deed as the revocation of the edict of Nantes, was easily persuaded to grant the request. And, accordingly, M. Bayle's *Critique Generale* was burnt by the hands of the hangman, and prohibited from being sold under pain of death. This sentence proved as impolitic as it was oppressive; for, being made as public as possible, it excited the curiosity of the people, and determined every one to peruse a volume which the king had thought worthy of such a hard fate. Mr Bayle endeavoured to conceal that he was the author; and so very different was the style of his "General Criticism" from that of his "Letter to the Sorbonne Doctor," that nobody could ever have suspected them to be written by the same hand. But the secret was very soon revealed by accident. M. Jurieu also wrote an Answer to Maimbourg; but, though able and conclusive, it was so inferior to Mr Bayle's, in the public opinion, as to be almost wholly neglected. This circumstance was a mortal offence to Jurieu, which he ungenerously imputed to Mr Bayle, and which he seems never to have forgiven.

About this time Mr Bayle was powerfully solicited to marry. The lady who was proposed to him, and who had consented to be his wife, was young, beautiful, sensible, amiable, and rich. But Mr Bayle, who had no ambition for wealth, and was afraid that the cares of a family would interrupt his studies, positively refused to enter into the matrimonial connection.

In 1683, he published a new edition of his Letter on Comets, under the title *Pensées Diverses écrites à l'occasion de la Comète qui parut au mois de Decembre 1680*; and also edited, at the request of some friends, several controversial pieces relating to the dispute between the Catholics and the reformed. In the following year he collected a number of fugitive pieces on the Cartesian philosophy, and gave them to the world in a volume entitled, *Recueil de quelques pieces curieuses concernant la philosophie de Mr Descartes*. He introduced them with a preface, in which he gives a succinct account of each of the treatises, and makes some enlightened, pertinent,

and feeling remarks on the degraded state to which the press was reduced in France by the law of royal privilege, and on the mischievous consequences which must attend such an inquisitorial and oppressive rule, wherever it is established.

In 1684 he began a literary journal. This mode of spreading knowledge, which now prevails so universally, and which has done more than any thing else to enlighten the world, was first introduced by Mr de Sallo, ecclesiastical counsellor in the parliament of Paris, who published the *Journal des Sçavans* in 1665. This work, which received great applause, was imitated at Rome in 1668 by Abbot Nazari in his *Journal*, and at Leipsic in 1682 by Menkenius, in his *Acta Eruditorum*. Mr Bayle was surprised that nothing similar had been attempted in Holland, where booksellers and learned men abounded, and where so much freedom was enjoyed, and he resolved to supply such an important desideratum in that country. About the beginning of the year 1684, indeed, a journal was begun at Amsterdam with the title of *Mercurius Sçavant*, by one de Blegny, a surgeon of Paris: but it was so abusive and so exceptionable in a variety of points, that, so far from seeming to Mr Bayle to supersede the necessity of the undertaking he had in view, it only stimulated him to commence it without delay. Accordingly, in the month of May the first number of his *Journal* came out, under the title of *Nouvelles de la Republique des Lettres*. This work, which continued to be published monthly, was divided into two parts; the first, consisting of copious extracts from other publications; the second, containing a catalogue of new books, accompanied with ingenious criticisms, and interesting anecdotes and accounts of the authors. It was calculated to gratify both the learned and the polite world. At first it was rather profuse in its commendations; but it assumed by degrees a less mild and flattering tone. Though strictly prohibited from being circulated in France, many copies of it were sold in that kingdom every month: and wherever it appeared it was read with great eagerness and universal applause.

This year he had an offer from the states of Friesland of a professorship of philosophy in the university of Francker: but though the salary there was nearly double of what he had at Rotterdam, and though the offer was a disinterested tribute to his literary merits, he declined accepting their invitation. His *Critique Generale* was in so much request, that a third edition was necessary. He published it with considerable amendments, particularly in the style, freeing it from those ambiguities and rhymes which, he observes, it is extremely difficult to avoid in writing the French language. Of this work he published a continuation in 1685, under the title of *Nouvelles Lettres de l'Auteur de la Critique Generale*, &c. The continuation was not so successful. The fears which the author had expressed in his advertisement were realised. It was misunderstood, disliked, and neglected. His journal, which had been anonymous during the first year of its existence, he now thought proper explicitly to avow; not so much, he said, to procure distinction to himself, as to shew that the magistrates of Rotterdam, from whose new illustrious school it proceeded, honoured the muses with their protection.

Mr Bayle was deeply affected by the revocation of the edict of Nantes, and the horrid persecutions to which the reformed in France were consequently sub-

jected; and felt still more indignant when he observed the popish writers boasting of their clemency, and celebrating the immortal glory which Louis the Great had acquired by rendering France entirely catholic. After speaking of these things in his *Journal* with more caution than was natural to him, he at last (1686) gave vent to his feelings in a little book, entitled, *Ce que c'est que la France toute Catholique sous le regne de Louis le Grand*, in which he passes the severest censures on France for the injustice, the treachery, the cruelties which it had practised towards the votaries of the protestant religion. This was followed by another volume written with the same general view, and in a more argumentative strain. Its title was *Commentaire philosophique sur ces paroles de Jesus Christ, contraignez les d'entrer*, &c. This work should be read by every statesman and divine, for the sound and liberal ideas of toleration which it inculcates, and for the strength of argument and clearness of illustration with which almost all its positions on that important subject are accompanied. He who, after a careful and candid perusal of it, would justify persecution in popish princes in any case, or non-toleration in protestants, unless it be identified with the safety of the state, we must pronounce to be neither an enlightened Christian, nor a wise citizen.

About this time Mr Bayle received letters from various quarters; from the French Academy, from the Royal Society of London, and from the Society of Dublin, approving highly of his *Journal*, and expressing in polite terms, their admiration of the genius which it indicated, and their sense of its utility to the cause of literature. But while this work advanced his reputation, it also involved him in some disagreeable disputes. Something which he had published in it, was particularly offensive to that strange, clever and eccentric woman, Christina Queen of Sweden. She made one of her servants communicate to him the ground of her complaint. This he answered by a note in his *Journal*, which would have satisfied any reasonable mind. But finding that the queen's displeasure was not to be removed so easily, he made a full recantation of his error both in the *Journal*, and in a letter which he was advised to address to Christina herself. The strain of this letter is adulatory and slavish. It is a great deal more than mere respect to the queen's elevated rank, or than mere complaisance to her headstrong humour. It is a practical exhibition of that belief which was then entertained by the reformed, as well as by the catholics, in the absolute and divine right of princes; and forms a striking and lamentable contrast to that noble independence of language which we should expect to find in all the writings of a protestant philosopher. The great object of Mr Bayle, however, was gained. The queen was satisfied. She sent him a gracious and friendly answer, and shewed him other marks of her favour. Mr Bayle having been seized with a fever at the commencement of the year 1687, in consequence of the labour and fatigue which the publication of his *Journal* obliged him to undergo, he was under the necessity of giving over that work. A continuation of it was undertaken at his request by Mr Beauval, under the title of *Histoire des Ouvrages des Sçavans*. But at the same time it was regularly published under the old title for about two years longer by the original printer of it, with the assistance of a Mr Larroque, a Mr Barin, and other literary characters.

Mr Jurieu being a man of intolerant temper, was displeased with the *Commentaire Philosophique*, and under-

took to write an answer to it, in which he at first suspected it to be the production of a cabal of French refugees, but afterwards distinctly laid it to the charge of Mr Bayle, who had been very anxious to make the public believe that he was not the author. Having, by proper care of himself, recovered from his illness, Mr Bayle published a continuation of his *Philosophical Commentary* by way of supplement; and took occasion to notice Jurieu's work, in such a manner as to make him contradict himself, and to expose him to ridicule and contempt. In 1690 there appeared a book, entitled, *AVIS Important aux Réfugiés sur leur prochain retour en France*. From what Maizeaux has stated, we have sufficient reason for concluding, that Mr Bayle was the author of this work. But as it contains a severe censure on the refugees, for pretended calumnies and attachment to republicanism, and is quite inconsistent with the strain of his other writings, we are at a loss to know the motives which he had for such a publication. Notwithstanding all that his biographer has said to account for this part of his conduct, we cannot but consider it as representing him in a very suspicious and unfavourable light. Indeed, the attempt to justify an action so hypocritical and base, is far more absurd than an implicit belief in the denial of Bayle himself, and the testimony of his eulogist, Mr Beauval. In the year following, one Goudet, a merchant in Geneva, composed a project for a general peace, which Mr Bayle perused in manuscript, and which was afterwards published with his concurrence. Jurieu, who had accused him of being the author of the *Advice to the Refugees*, connecting it in this view with the project for a general peace, thought proper to regard them as decisive proofs of an existing conspiracy in favour of the court of France; and, openly charging Mr Bayle as one of the leaders in it, pronounced him to be an *impious and profane person, without honour or religion, a traitor, a deceitful man, an enemy to the state; a person to be detested and deserving of corporal punishment*. To prevent the injury which such a serious attack, if unresisted, must have done to his reputation and his interests, Mr Bayle went to the magistrates of Rotterdam, asserted his innocence in the strongest terms, and demanded that he should not suffer in their estimation till the case was fairly tried. And not satisfied with this appeal to the civil authority, he deemed it expedient to vindicate his character before the world by a public refutation of Jurieu's ridiculous and malevolent libels. This he did in a work entitled, *La Cabale Chimérique*, &c. In this work he kept no terms with Jurieu. He proved him to be ignorant, stupid, arrogant, and wicked; and held him up as a man to be laughed at for his folly, and detested for his malevolence. The burgomasters of Rotterdam, to whom Jurieu applied for protection, advised a mutual reconciliation, and forbade the combatants to publish any thing against one another, without first submitting it to the inspection of Mr Bayer, pensionary of the city. This order, however, was violated by Jurieu, and a long controversy ensued, in which he reaped nothing but disgrace, and which at length was terminated by a dignified silence on the part of Mr Bayle.

In 1693, Mr Bayle was deprived of his professorship and of the salary annexed to it, and even prohibited from teaching privately. This harsh treatment he himself ascribed to the machinations of Jurieu, and to the offence which, through his means, the magistrates had taken at the Letter on Comets. But it would appear that he was mistaken as to the cause of his deposition. The

true cause is to be found in the unwarrantable fears, and rash policy, and tyrannical conduct of King William. That prince had heard of the "Project for a General Peace;" and, as the publication of such treatises at Amsterdam had formerly been instrumental in bringing about the peace of Nimeguen, he was afraid that there was a design to make use of the same methods at Rotterdam for putting an end, however imperious, to the important contest in which he was engaged. He therefore, without examining the project itself, or making any enquiry into the character of Mr Bayle, ordered the magistrates to expel him from his office. These men, though perfectly satisfied that the suspicions of William were groundless, and that they were commanded to do what was both unjust and cruel, obeyed the order they had received without addressing one word of remonstrance to the prince, or condescending, as they had promised, to hear the defence which Mr Bayle might think it necessary to adduce. This act of undeserved severity had no disgrace in it except for those by whom it was committed. It neither greatly disturbed the tranquillity, nor at all injured the reputation of Mr Bayle; on the contrary, he bore it with the utmost fortitude and composure. The sense of the public was loudly expressed in his favour. And the same stroke which deprived him of an honourable employment and an independent revenue, afforded him the leisure that he would not otherwise have found, for the composition of a work on which his future fame was principally to rest.

This work was his *Historical and Critical Dictionary*. The original plan, of which he published a specimen in 1692, under the title of *Projet et Fragmens d'un Dictionnaire Critique*, was to collect, under the different articles of which he should treat, all the errors and mistatements that were to be found in other dictionaries, and to make remarks on the character of authors as occasion should offer. However interesting and useful such a publication might be deemed, it did not meet with that degree of approbation which could justify the prosecution of his design. He therefore abandoned it, and applied himself to the composition of another dictionary on a more liberal and extended scale. So diligently did he labour, and so much had he his learning at command, that, notwithstanding the interruptions which he repeatedly received from the malice of Jurieu, the frequent necessity he was under of publicly defending himself, the painful indisposition which he suffered in consequence of the closeness and severity of his studies, and other serious disadvantages under which he laboured, his new work, in two folio volumes, was ready for publication in about 4 years after it was begun. It came out in 1697, with the following title, *Dictionnaire Historique et Critique par Monsieur Bayle*. He put his name to this work, contrary to his former unvaried practice, not from any change in his sentiments on that point, but because the states of Holland made it the condition of granting the privilege for which his bookseller had applied. The duke of Shrewsbury, at that time secretary of state in England, expressed a wish that it should be dedicated to him; but Mr Bayle declined complying with his grace's request, both because he had often made a jest of dedications, and because he disdained to praise any one who held an official situation under a prince from whom he had experienced such cruel and unprovoked injury.

The plan of the dictionary is well known. It consists of two parts: one of which is a succinct narration of

facts, and the other "a large commentary," as Mr Bayle himself expresses it "a medley of proofs and discussions, a criticism of many errors, and sometimes a long train of philosophical reflections." The public were highly pleased with it when it first appeared, and to the present day it has continued to be a work of great authority and repute. The learning and acuteness of the author are every where conspicuous. That freedom of disquisition which contributes so much to the elucidation of truth, is indulged in with little reserve. The mistakes and misrepresentations of other critics are exposed. New facts are brought forward. The merits and demerits of character are ascertained with much precision. The history of literature is, in many cases, well illustrated. Superstition and enthusiasm are happily ridiculed. Many maxims of a political, moral, and philosophical kind are deduced and established. In short, it contains a great deal of useful and entertaining matter, and is written in that easy, perspicuous, and agreeable style, by which all Mr Bayle's compositions are distinguished.

Mr Bayle's dictionary procured for him a high degree of celebrity, but it also involved him in much disagreeable controversy. Jurieu, of course, was the very first to attack and decry the merits of the work. Mr Le Clerc found fault with his statement of the Manichean system. Mr Tessier blamed him for criticising falsely, several passages in his "Additions to the Eulogies of Learned Men." Mr Jaquelot reproached him for his alledged heterodoxy respecting free will, moral evil, and Pyrrhonism. And by many others he was subjected to the severest censure and animadversion. But against all of them he defended himself with boldness, ability, and success. The consistory of the Walloon church of Rotterdam, were induced, through the influence of Jurieu, to examine the dictionary. They found many parts of it inconsistent with sound doctrine and with good morals. They communicated their remarks to Mr Bayle, and gave him an opportunity of answering for himself. With his answers, which consisted partly of explanation, partly of concessions, and partly of promises to correct or expunge what had given offence, they declared themselves to be satisfied, and concluded their proceedings with presenting to him a memorial of the principal things to which they requested his attention in the second edition of his dictionary. Jurieu seems to have been mortified and displeased that Mr Bayle did not experience a more rigid treatment from the consistory. But that enmity must have been excessive indeed, which was not fully gratified by the reproofs that were administered, and the restraints that were imposed on the philosopher, by the humble tone of acquiescence and submission in which he replied to the ministers, and by the injunctions which they gave him to behave with greater moderation towards Mr Jurieu; a pastor whose ministry and labours had been and still were of singular edification to the church.

The second edition of the Critical Dictionary had fatigued Mr Bayle; and, in order to relieve his mind a little, he wrote and published in 1703, a book entitled, *Reponse aux Questions d'un Provincial*, which treats of a great variety of subjects in an easy and agreeable manner, and is neither so profound as to require any depth of study, nor so superficial as to be unworthy of the notice of the learned. It extended to five volumes, which came out successively at considerable intervals, and which the author sometimes made the vehicle of those

replies which he thought it necessary to make to his antagonists. He also published in 1704, a continuation of his Treatise on Comets, under the title *Continuation des Pensées Diverses, &c.* Having occasion in this work to criticise the system of Doctors Cudworth and Crew concerning plastic and vital natures, he was keenly attacked by Mr Le Clerc, who had embraced that system, and thought himself bound to support it. The controversy was carried on for some time with great eagerness on both sides; Mr Bayle maintaining his opinions with his usual temper and acuteness, and Mr Le Clerc opposing them with violence, unfairness and abuse.

While engaged in these disputes, he was seized with a distemper in the lungs. Knowing it to be incurable, he refused to take any remedy that was prescribed. And after labouring under it for six months, during which time he shewed the utmost fortitude and patience, and continued to write as if he had enjoyed perfect health, he died in 1706, at the age of 59; and was buried in the French church at Rotterdam. His death was deeply and universally regretted by the literary world, and by a vast number of friends that his merits had procured for him in almost every country. He was unquestionably a man of great learning and ability. His intellectual powers were naturally strong, and he had improved them by a long and unwearied course of study. The character of a freethinker has been generally ascribed to him. Doubtless he was a freethinker, both in the good and in the bad sense of that appellation. Those subjects, which had been hitherto viewed but on one side, by the fearful eye of ignorance, prejudice, and superstition, he took the liberty of turning over and examining with boldness and impartiality. He scrupled not to give an explicit statement of the difficulties which sometimes perplexed, and sometimes destroyed his belief in doctrines of heretofore unsuspected or unchallenged credit. And he set an example, at that period extremely rare, of investigating, with minuteness and candour, whatever dogmas are inculcated, before we allow them to become articles of faith or principles of action. In this respect Mr Bayle, it must be admitted, acted a rational and useful part. But, at the same time, it cannot be denied, that, in many points, he carried his scepticism to an unreasonable length, and often gave an interest to the arguments of infidels which does not belong to them, and a prominence which cannot fail to be injurious to young and unwary readers. Some parts of his writings, especially of his dictionary, are stained with indelicate and obscene quotations from the volumes of other authors. This is a defect much to be lamented, both on account of its intrinsic turpitude, and its debasing tendency. It arose, however, rather from a laudable and anxious wish to support the facts and illustrate the positions that were stated, than from any peculiar depravity in the passions and habits of Mr Bayle, whose moral character, even in the judgment of his enemies, was pure and irreproachable. He is described by those who were personally acquainted with him, as having been modest and unassuming, constant in his friendships and disinterested in his kindness, placid and equable in his temper, cheerful and affable in conversation, frugal in his domestic and individual habits, abhorrent of fraud and insincerity, grateful to those from whom he received any assistance, and addicted to no pleasures but those that arise from the acquisition of knowledge and the exercise of the best affections. This account may be somewhat exaggerated.

by the partiality of friendship, but seems to be accurate in all its leading features.

Mr Bayle left a great many manuscripts, very few of which were given to the world. See Maizeaux's *Life of Bayle*; *Eloge de Mr Bayle* par Mr de Beauval; *Mr Bayle's Letters*, &c. (τ)

BAYONET, the name of a short broad dagger, the round handle of which is fitted to the extremity of muskets, so that it may be either used alone, or employed like a spear when it forms one piece with the musket. The bayonet appears to have been first manufactured in the town of Bayonne, in the department of the lower Pyrenees, from which it derives its name.

This instrument, which has been used with such fatal effects by the British and French armies, was first introduced by the French about the end of the 17th century, and was employed with great success in the war of 1689. See Folard's *Comment. sur Polyb.* vol. i. p. 155. (q)

BAYONNE, the *Lapurdum* of the ancients, is the largest, though not the chief, town in the department of the Lower Pyrenees. It is beautifully situated about a league from the western coast of France, at the conflux of the rivers Nive and Adour, by which the town is divided into three parts, viz. the large town on one side of the Nive; the small town between the Nive and the Adour; and the suburb of St Esprit, on the other side of the Nive. A regular square citadel, constructed by Vauban, commands the whole city, which is likewise defended by smaller fortifications. The cathedral of Bayonne is a venerable edifice. The *Place de Grammont* is reckoned the most beautiful part of the city; and so fine is the situation of the town, that there is no part of it from which we cannot see the whole of its buildings, the two rivers which water it, the Bay of Biscay, and the towering summits of the Pyrenees. The *Allées Marines*, or the quay, is a superb and much frequented promenade. A wooden draw bridge, which allows vessels to pass, and where a small toll is collected, connects the suburbs with the town.

Bayonne carries on a considerable trade with Spain, to which it exports woollen cloths, silks, cottons, ribbands, and hardware, in exchange for wine, oil, and wool, and articles from the American colonies. The hams of Bayonne are famous in every part of Europe; and its wines, raisins, and chocolate, are exported in considerable quantities to the north of Europe. The wines of Cape Breton and of Anglet are particularly excellent. Though the harbour of Bayonne is safe, yet its entrance is narrow and dangerous. Masts from the Pyrenees are brought down the rivers to Bayonne, from which they are exported to Brest and other ports of France. The old Biscayan, or Basque language, is generally spoken by the common people. The head dress of the Basque women is said to have a wonderful effect. The chief amusements of the place are bull fights and tennis. Population 15,190. W. Long. 1° 30' 6", N. Lat. 43° 29' 21". See Link's *Travels in Portugal*, chap. vi. (q)

BAYREUTH. See **BARRETH**.

BAZARS, the name given in Turkey and Persia to the exchanges, or to places of public resort, like the market-places of this country. An account of the different bazars, which are often remarkable for their magnificence and splendour, will be found under the names of the towns to which they belong. (j)

BDELLIUM, an aromatic gum, formerly used as a

perfume and a medicine, but now out of use. It resembles myrrh in its external appearance, and in some of its properties. Its smell is fragrant, and its taste bitter and pungent. (w)

BEAM. See **CARPENTRY**, and **STRENGTH OF MATERIALS**.

BEANS. See **AGRICULTURE** *Index*.

BEAR, a wild animal of the mammalia tribe, of which naturalists have enumerated nine different species. In this enumeration, however, they include several animals which have very few properties in common with the bear, and may with greater propriety be reduced under different classes; such are the glutton, the racoon, the beaver, and the different species of the badger. Of the bear, properly so called, there are only three species: the white, or polar bear, called also the sea bear, or *ursus maritimus*; the brown bear, or *ursus arctos*; and the black bear, or *ursus Americanus*. The polar, or sea bear, inhabits the coasts of the Frozen Ocean, and some of its eastern and northern isles, and is not infrequently conveyed on rocks or islands of ice as far south as Newfoundland. He is much stronger, larger, and fiercer, than either the brown or black bear, and sometimes measures no less than twelve feet in length. His face and neck are more elongated than in the other species, and he is covered with a thick white fur. During winter he lies buried amidst the snow, in a state of torpor; in summer he lives chiefly on fish, but occasionally attacks the seals. The chase of the white bear is a collateral occupation of the mariners who visit the coasts of the Frozen Ocean for the capture of the morsh. In the forests of Great Tartary, Muscovy, and Lithuania, bears are sometimes found of a white colour; but though they resemble the polar bear in that single particular, they are in every other respect completely different. The colour of these animals does not depend, like that of the hare, or ermine, on the rigour of the climate; and they might therefore be regarded as a fourth species, did not the intermixture of brown and white, to be seen in some bears, which are plainly an intermediate race between the white land bear and the brown or black, indicate that the former is only a variety of one of those species.

The brown bear is a fierce carnivorous animal, so extremely voracious, that he not only attacks flocks and herds, but even devours carcasses when in a putrid state. The black bear, on the contrary, can never be brought to taste of flesh, nor has he ever been known to attack any animal for the sake of devouring it. Roots and vegetables of every kind constitute his principal food; but his favourite repast is honey and milk, of which the brown bear likewise is excessively fond. The black bear is very rare in Europe, but is extremely common in the forests of America. The brown bear is to be found in almost every latitude of Europe, in China, Japan, Arabia, Egypt, and as far as the island of Java.

The form of the bear is rude and unshapely. His unwieldy body is covered with a coarse and shaggy hide; his legs are thick and muscular; and the long flat soles of his paws, though they enable him to tread with peculiar firmness, render his pace, at the same time, very awkward and heavy. Yet though thus unseemly in his appearance, his senses are extremely acute, and his form combines many advantages which few other animals enjoy. Though his eye is small, and his ear short, in proportion to his size, he possesses in great perfection the senses of hearing and seeing. In

no animal is the sense of smelling so exquisite; for the internal surface of his nose is not only very extensive, but of the texture best calculated to receive impressions from odoriferous bodies. His feet, armed with sharp claws, and capable of grasping, somewhat in the manner of a hand, enable him to climb with great facility the most lofty trees: With his fore paws he can strike a dreadful blow; he can rear himself at pleasure on his hinder paws, and, seizing his adversary in his embrace, can easily squeeze the strongest man to death. The bear delights in solitude, and chooses his den in the precipices of lonely mountains, or in the deep recesses of some gloomy forest. Here he passes the greater part of the winter, without ever stirring abroad. He is not deprived of sensation, like the dormouse or marmot; nor has he, like the ant or the bee, laid up any hoard of provisions for the season. But being excessively fat when he retires in autumn, he seems to subsist chiefly on his own exuberance; the under part of his paws, too, is composed of glands, which are at that time full of a white milky juice, and during his retirement he is said to derive considerable nourishment from sucking them. When he first crawls abroad again in spring, he is extremely lean and feeble, and his feet are so tender that he moves with difficulty. These animals copulate in autumn; the period of gestation is about four months; and only one or two are produced at a birth. It was long believed that the cub, when first brought forth, was a mere unformed lump, until it was licked into shape by the dam; but the truth is, that the fœtus of the bear is as completely formed before parturition as that of any other animal. The young bear is very slow of growth, and follows the dam for at least a year; during all which time she displays uncommon tenderness for her offspring, and will encounter any danger in its defence.

The bear is in many respects so serviceable to man, that he has at all times been a favourite object of chase, and many ingenious methods have been devised for catching or destroying him. The most simple and common method is to attack him with deadly weapons, such as spears, clubs, or fire-arms. In many parts of Siberia the hunters erect a scaffold of several heavy balks piled on each other, under which is placed a trap, which the bear no sooner touches, than he brings down the whole scaffold upon himself, and is crushed beneath its weight. Sometimes pits are dug, in which are fixed smooth, solid, and sharp-pointed posts, rising about a foot from the bottom. The mouth of the pit is carefully covered over with sods, and across the bear's track is placed an elastic bugbear, connected with a thin rope. As soon as he touches the rope, the bugbear starts loose, and the terrified animal, flying with precipitation, falls violently into the pit, and is pierced by the pointed stake. Should he escape this snare, caltrops*, and other annoying instruments, await him at a small distance. Amongst them is a similar frightful log; and the persecuted beast, in striving to get free, only fixes himself faster to the spot, where the hunter lies in ambush ready to take his aim. Nor is it only upon the ground that the bear is exposed to danger from the cruel invention of man. In some parts of America it is common to set fire to the trees on which they take refuge, and they are easily dispatched as they descend.

The Koriaks attach a noose to the summit of a crooked tree, hanging something along with it of which the bear is fond. Lured by this bait, he eagerly climbs the tree: in attempting to seize the bait, his neck is introduced into the noose, and the tree, springing violently back into its former direction, keeps the animal suspended in the air. The plan adopted by the mountaineers of Siberia to make the bear kill himself, is yet more singular and ingenious. They fasten a very heavy block to a rope, terminating at the other end with a loop. This block they lay near a steep precipice in the wonted path of the bear. Finding his neck in the noose, and unable to proceed for the clog, he takes it up in a rage, and, to disencumber himself, throws it down the precipice; he is naturally pulled after it, and is generally killed by the fall. If he happens to survive the first shock, he again drags the block up the steep, and renews his efforts for freedom, till, with increasing fury, he either sinks nerveless to the ground, or, by one decisive plunge, puts an end to his torments. In Kamtschatka the bears are so harmless and familiar, that women and girls go out fearless amidst a whole drove of them to gather herbs and roots, and they often approach them to eat out of their hand. They have never been known to attack a man, except when roused from their sleep, and even when wounded seldom turn upon their pursuer. Yet this harmless character of the Kamtschadale bear gives him no security from the persecutions of mankind. Armed with clubs and spears, the hunter traces the bear to his retreat, who, intent only on defence, gravely collects the faggots brought by his persecutor, and chokes up the entrance to his den. The hunter then bores a hole through the top of the cavern, and in perfect security spears his defenceless foe. "It would be difficult," says Mr Tooke, "to name a species of animals, excepting the sheep, so variously serviceable to man as the bear is after his death to the Kamtschadales. Of the skin of this animal, they make beds, covertures, caps, gloves, and collars for their sledge-dogs. Those who go upon the ice for the capture of marine animals make their shoe soles of them, which have this advantage, that the wearer is not in danger of slipping with them. The fat of the bear is held in great estimation as a very savoury and wholesome nourishment, and when melted, and thus rendered fluid, supplies the place of oil. The flesh is reckoned such a dainty, that they seldom eat it alone, but usually invite a number of guests to partake of the delicious repast. The intestines, when cleansed and properly scraped, are worn by the fair sex as masks to preserve their faces from the effects of the sun-beams, which here, on being reflected from the snow, are generally found to blacken the skin, by which means the Kamtschadale ladies preserve a fine complexion. The Russians of Kamtschatka make window-panes of the intestines of the bear, which are as transparent and clear as those made of Muscovy glass. Of the shoulder blades are made sickles for cutting grass. A light black bear-skin is one of the most comfortable and costly articles of the winter wardrobe of a man of fashion at Petersburg or Moscow, and even the small white band of a belle is split into the large bear-muff, which covers half of her elegant shape." See Buffon's *Natural History*, vol. vi. 12mo; Tooke's *View of the Russian Empire*, vol. iii. p. 53—59. (μ)

* The caltrops are irons with four spikes, so formed, that whatever way they fall, one point always lies upward, generally thrown in breaches and on bridges to annoy an enemy's horse. This name is also given to an instrument with three iron spikes, used in hunting the wolf.

BEARD, the hair which grows upon the chin and contiguous parts of the face, in males, and sometimes, though rarely, in females, at the age of puberty. The growth of the beard, in men, is a sign of maturity, or approaching manhood; and takes place at the period when the seminal secretion commences. When that secretion stops, from any derangement of the system, it is said that the beard falls off; and when the secretion discontinues, in old age, the beard grows thin, and flaccid. The beard has, therefore, an intimate sympathy with this change in the constitution of the male. Bearded women are all said to want the menstrual discharge; and various instances are given by Hippocrates, and other physicians, of grown females, especially widows, in whom beards appeared upon the discontinuance of this discharge.

Many instances are recorded, by different writers, of women with remarkably long beards. Eusebius Nierembergius mentions a woman who had a beard reaching even to her navel. Charles XII. had in his army a female grenadier, who, both by her courage and her beard, might well have passed for a man. She was taken at the battle of Pultowa, and carried to Petersburg, where she was presented to the czar in 1724; at which time her beard measured a yard and a half. We read in the Dictionary of Trévoux, that there was a woman seen at Paris, who had not only a bushy beard on her face, but likewise her whole body covered over with hair. The celebrated Margaret, governess of the Netherlands, had likewise a very long stiff beard, on which she greatly prided herself, and was very solicitous to preserve it undiminished. The Lombard women, it is said, when accompanying their husbands to the field of battle, contrived to assume the appearance of beards, by an ingenious disposition of the hair of their heads upon their cheeks; and the Athenian women, according to Suidas, did the same thing in a similar case.

The American savages have thin and scanty beards, which they are in general solicitous to extirpate by the roots. The beard of the negro is short and bushy, like his hair; that of the Greenlander, Samoiède, and of all savages who live a life of hardship and penury, is generally thin, and stunted in its growth. The fashion of the beard has greatly varied in different ages and countries; for sometimes it has been deemed honourable and becoming to permit it to grow to its utmost extent; and sometimes it has been fashionable to cut it off entirely, or to permit it to remain only on a particular part of the face, or cut into a particular form. In mentioning the most remarkable of these peculiarities, we shall speak, 1st, Of the Eastern nations; 2dly, Of the ancient Greeks and Romans; and, 3dly, Of the modern inhabitants of Europe.

I. Among the eastern nations, the ancient Egyptians left only a little tuft of hair at the extremity of the chin. The Hebrews wore a beard on the chin, but not on the upper lip; and they were prohibited by Moses to manage their beards after the Egyptian fashion. The Jews of the present day suffer a little fillet of hair to grow from the lower end of their ears to their chins, where, as well as on their lower lips, their beards are in a pretty long bunch. Strabo relates, that the ancient Indian philosophers, called Gymnosophists, were particularly solicitous to have long beards, as symbolical of wisdom. The ancient Assyrians and Persians also prided themselves on the length of their beards; and Chrysostom informs us, that the kings of Persia had their beards interwoven, or matted, with gold thread;

a practice which was also adopted by some of the first kings of France.

According to Le Compte, the Chinese greatly affect long beards; which, however, nature has denied them; and there is nothing on account of which they are more envious of Europeans than the great length of their beards. The Tartars, out of a religious principle, as Kingson assures us, waged a long and bloody war with the Persians, considering them as infidels, because they would not cut their whiskers after the Tartarian mode, though, in other respects, of the same faith with themselves. The Persians are almost the only Mahometans who clip the beard, and shave above the jaw; and on this account are deemed heretics by their neighbours. The Arabs make the preservation of their beards a capital point of religion, because Mahomet never shaved his. Among the Turks there is nothing more infamous than to have the beard cut off. The slaves in the scraglio are shaved as a mark of servitude; and are only permitted to allow their beards to grow when they regain their freedom. The custom of anointing the beard prevails among the Turks, as it did among the ancient Jews and Romans; and one of the principal ceremonies observed in the serious visits of this people, is to throw sweet-scented water on the beard of the guest, and to perfume it afterwards with aloes-wood, which adheres to this moisture, and gives it an agreeable smell. The Turks, when they comb their beards, hold a handkerchief on their knees, and carefully gather the hairs that fall, which they afterwards deposit in the place where they bury the dead. The Turkish wives salute their husbands, and the children their fathers, by kissing the beard; and the same ceremony is used by the men when they reciprocally salute one another.

II. Among the ancient Greeks and Romans, the beard was scarcely less venerated than among the eastern nations. Homer speaks in high praise of the snow beards of Nestor and king Priam; and Virgil celebrates that of Mezentius, which was so long and thick as to cover all his breast. Pliny the younger mentions the white beard of Euphrates, a Syrian philosopher, which, he says, inspired the people with respect, mingled with fear; and Plutarch speaks of the long white beard of an old Laconian, who, being asked why he allowed it to grow so luxuriantly, replied, "In order that, having my white beard continually in view, I may do nothing unworthy of its whiteness." The Greek philosophers distinguished themselves from the vulgar by the length of their beards: a practice, according to Laetius, first introduced by Antisthenes, (l. 6.) The Roman philosophers affected the same distinction, as we find in Horace:

Tempore quo me
Solatus jussit sapientem pascere barbam.
HOR. l. ii. sat. iii. v. 34.

The Greeks continued to wear their beards till the time of Alexander the Great, as Athenæus informs us, from Chrysippus; adding, that the first who cut his beard at Athens, ever after bore the appellation of *κατογγοί*, or *shaven*. The Macedonians, however, appear to have cut their beards before this period; as Philip, the father of Alexander, and Amyntas and Archelaus, his predecessors, are represented on medals without beards. The reason assigned by Plutarch, for Alexander commanding the Macedonians to be shaven, was,

that their beards might not give a handle to their enemies in the day of battle. Before one of Alexander's battles, we are told, when Parmenio presented himself, to give an account of his arrangements, and to enquire whether any thing remained to be done? "Nothing," said Alexander, "but that the men should shave." "Shave!" cried Parmenio: "Yes," replied the king, "do you not consider what a handle a long beard affords to the enemy?" (*Dornav. Amphith. Sapientie.*) The Greeks continued to shave the beard till the time of Justinian, under whose empire long beards came again into fashion, and so continued till Constantinople was taken by the Turks.

The Romans anciently wore long beards and hair, as we find by a variety of authorities. Thus Livy, speaking of the senators who remained in Rome, after the entrance of the Gauls, mentions, that they wore a long beard: *ut tum omnibus promissa erat*, (lib. v.); and Cicero, in his oration for Cælius, mentions the *barba horrida quam in statuis antiquis et imaginibus videmus*. According to Pliny, the Romans knew nothing of shaving till the year of Rome 454, when P. Ticinius brought over a number of barbers from Sicily; and he adds, that Scipio Africanus was the first that introduced the mode of shaving every day. The first fourteen Roman emperors shaved; but Adrian wore his beard, in order, as Plutarch informs us, to hide the scars on his face. Antoninus Pius, and Marcus Aurelius, wore a beard, under the character of philosophers.

The first shaving of the beard was a matter of great solemnity among the Romans, and was generally performed when the *toga virilis* was assumed. The first growth of the chin was consecrated to some god, usually to the Lares; visits of ceremony were paid on the occasion; and persons of quality had their children shaved, for the first time, by others of the same, or of greater quality; who, in this manner, became the adoptive fathers of the children. Nero consecrated his beard, when first shaved, to Jupiter Capitolinus, in a gold box set with pearls. For the sake of distinction, the Roman slaves wore their beard and hair long; and, when manumitted, they shaved the head in the temple of Feronia, and put on a cap, or *pileus*, as a badge of liberty. The Roman soldiers, however, seem to have worn their beards short, and frizzled, as we find upon ancient monuments.

In time of grief and affliction, the Romans suffered their beard and hair to grow; whereas the Greeks, in time of sorrow, shaved themselves, and cut their hair, (*Senec. Benef. v. 6.*); which was also the custom among some barbarous nations. On like principles, the custom of letting the beard grow is a token of mourning in some countries, as that of shaving is in others.

III. Among the inhabitants of modern Europe, the fashion of wearing the beard, like all other fashions, has undergone a variety of vicissitudes. Most of our Gothic ancestors shaved, or wore hair only on the upper lip, or in the form of mustaches. The Lombards, however, who invaded Italy, were remarkable for the length of their beards; and hence their name of *Longobardi*. Among the Franks, who wrested Gaul from the Romans, a long beard became a characteristic of nobility; as, under the Roman authority in that country, none but nobles and Christian priests were permitted to wear it. The Merovingian, or first race of kings in France, were, on this account, particularly solicitous of copious beards and flowing hair. They are described by Eginhard, the

secretary of Charlemagne, as coming to the assembly of the people, in the field of Mars, seated on a throne, in a carriage, or waggon, drawn by oxen, with long beards and dishevelled hair: *crine profuso, barba submissa, solio residerent, et speciem dominantem offingerent*.

The ancient Britons, in the time of Cæsar, wore no beards, except on the upper lip. But the Anglo-Saxons, on their arrival in Britain, and for a considerable time after, allowed their beards to grow. When, however, the Normans possessed themselves of the country, the beard had been reduced to its ancient standard, and was entirely proscribed by that people, who held beards in abhorrence. It is mentioned by some of our ancient historians, as one of the most wanton acts of tyranny in William the Conqueror, that he compelled the English, who had been accustomed to allow the hair of their upper lips to grow, to shave their whole beards. This was so disagreeable to some of the people, that, rather than relinquish their whiskers, they chose to abandon their country. The Russians, it is well known, shewed an equal repugnance to be shaved, when they were ordered to part with those beards, of which their ancestors had enjoyed the undisturbed possession, by an edict of Peter the Great. Many of them chose rather to pay a fine, or tax, than submit to this degradation; and those who were too poor, or too parsimonious to comply with this alternative, religiously preserved the beard that was shorn off, and had it deposited in their coffins, that they might present it to St. Nicholas, on his refusing to admit them into heaven as beardless Christians.

In the middle ages of Europe, the beard was occasionally in high repute: Thus, in the 10th century, king Robert of France, the rival of Charles the Simple, was not more famous for his exploits than for his long white beard, which he suffered to hang down on the outside of his cuirass, to encourage his troops in battle, and rally them when defeated. In the 14th century long beards were much in fashion, and continued to be the mode till the close of the 16th century. The emperor Charles V., pope Julius II., and Francis I. of France, were all great admirers of long and bushy beards. At this period, John Mayo, a celebrated painter in Germany, had so vast a beard, that he was nick-named John the *Bearded*. Though he was a tall man, it was so long that it would hang upon the ground when he stood upright; so that he usually wore it fastened to his girdle. The emperor Charles used to take great pleasure in seeing this extraordinary beard unfastened, and the wind blowing it against the faces of the lords of his court. The beard of sir Thomas More is honourably noticed in history; and we find, from the portraits of bishop Gardener, cardinal Pole, &c. that beards were of an uncommon size in England in the reign of Mary I.

The beard of Henry IV. of France, which was square in form, was an object of much admiration, on account of the majesty which it communicated to the fine open countenance of that amiable monarch. Beards, therefore, were in the zenith of their reputation during this auspicious reign. But no sooner was the throne occupied by the successor of this monarch, Louis XIII. then a beardless youth, than,—such is the instability of all human greatness!—beards were entirely proscribed, or reduced to the insignificant size of whiskers. The duke of Sully, however, evinced his attachment to the memory of his master, by wearing the beard of the ancient court, notwithstanding the ridicule it brought

upon him. Whiskers continued to prevail during the early part of the reign of Louis XIV. They were the ornament of Turenne, Condé, Colbert, Corneille, Molière, &c.; and the king himself took a pride in wearing them. Much pains was bestowed in rendering them captivating during this age of gaiety and gallantry; and the beauty of a lover's whiskers was then a subject of exultation to a favourite fair.

The Spanish beard suffered degradation from a cause similar to that which occasioned its dishonour in France. Philip V. ascended the throne with a shaved chin; the courtiers imitated the prince, and the people, in turn, the courtiers. This revolution, however, was not congenial to the feelings of the nation; and there is a Spanish proverb which says, *Desde que no hay barba, no hay mas alma*. "Since we have lost our beards, we have lost our souls." The love of ancient usages, and a certain gravity of character, have induced this people to retain the whisker as a mark of dignity, when the progress of refinement has exploded the beard from almost every part of Europe.

The respect in which the Portuguese held their beards during the reign of queen Catherine, is evinced by the remarkable anecdote of the brave John de Castro pledging one of his whiskers, as the best security he could offer to the inhabitants of Goa in India, for the repayment of a sum of money which he had borrowed for the use of his fleet. The people, however, relying implicitly on his honour, requested him to retain both the money and the whisker. Among the early French, all letters that came from the sovereign had, for greater sanction, three hairs of his beard on the seal. There is still extant a charter of 1121, which concludes with the following remarkable words: *Quod ut ratum et stabile perseveret in posterum, presentis scripto sigilli mei robur apposui cum tribus filis barbe mee*.

We shall take leave of the subject of beards, with a word or two on those of ecclesiastics. During the first ages of Christianity, the priests were sometimes enjoined to wear their beards, from a notion of too much effeminacy in shaving, and that a long beard was more suitable to ecclesiastical gravity; and sometimes they were enjoined to shave, that pride might not lurk beneath a venerable beard. On the separation of the Greek and Roman churches, the practice of shaving has become common among the Romanists, by way of opposition to the Greeks, who have continued to pay great reverence to a well covered chin; and are greatly scandalised at the beardless images of saints in the Roman churches. The shaving of the chin, and likewise of the head, according to the true ecclesiastical tonsure, is regulated by various statutes of the Romish church; and the form of prayer is still extant which was employed in the solemnity of consecrating to God the beard of an ecclesiastic, when he was first shaven. By the statutes of some monasteries, it appears that the lay monks were to let their beards grow, and the priests only to shave; and a writer of the seventh century complains, that the manners of the clergy had become so corrupted, that they could not be distinguished from the laity by their actions, but only by their want of beards. (m)

BEARING NOTES, in music, in the tuning of keyed instruments, harps, &c. signify those notes between which the most erroneous or highly tempered fifth is situate, on which also the *wolf* is said to be thrown: Many tuners begin at C, and tune upwards, through the

progression of fifths, C G D A E B \flat G \flat D and \flat A, and then stop, and begin again at C, the octave above the former note, and tune downwards, through the fifths c F \flat B and \flat E, and thus the resulting fifth \flat A \flat E produces *bearing notes*; owing to each fifth having been made more or less flat than the system of twelve notes will bear, the *least sum* of all their errors or temperaments being the DIASCHISMA, (see that article); for, had each of these fifths been tuned flat, just $\frac{1}{12}$ part of \sharp , (see Plate XXX.), the resulting fifth would have been also $\frac{1}{12}$ \sharp flat, and in this case there could not be said to be any bearing notes. See EQUAL TEMPERAMENT. It should be observed, that some tuners are in the habit of throwing their *wolf* into the fifth \flat A \flat D, and others into that of \flat D \flat G, which last, as being nearest to the middle of the whole progression of fifths, seems its most appropriate place for general use. See TEMPERAMENT. (g)

BEAT, in Music, is a transient grace or ornament in the performance of a note, where either of these marks \sim or χ are placed over it, denoting that a kind of shake is to be made, by beginning with the *half tone below* the given note, and quickly repeating the given note and that: on the contrary, the SHAKE, marked \surd is effected by beginning on the note *above* the given one (whether a half or whole tone distant) and repeating the given note and it alternately: the TURN differs from both of these in using the notes above and below the given one. When therefore a whole tone lies below any note marked for a *beat*, an accidental sharp is to be supposed on that lower note, except that A is seldom thus sharpened in a beat. There are other varieties of beats sometimes used, particularly by the German musicians; for which see Dr Callcott's *Musical Grammar*, Arts. 118 to 121. (g)

BEATINGS, in Music, is a term used by some to express those periodical jarring sounds, often made by the irregular vibrations of two strings, pipes, &c. sounding together, which, as Mr Emerson observes, occasion a repetition of noises like *waw, aw, aw, aw*, or *yá, yá, yá, yá*; these are called *beats* by Dr Robert Smith, Mr Emerson, and, we believe, every other mathematical writer that notices the phenomenon. (See BEATS.) Earl Stanhope, we are aware, in a letter of his, printed in the *Philosophical Magazine*, vol. xxviii. p. 150, has laboured to make a distinction between the meaning of *beats* and *beatings*, in order to identify the former with the pulses or VIBRATIONS of the sounds themselves, and to denominate the above phenomenon by the exclusive use of the term *beatings*; but his lordship's reasoning having failed in convincing us, we shall, with the late Dr Robison and others, continue to consider and use *beat* and *beating* as synonymous terms. (g)

BEATS, or BEATINGS, in Music, are an audible phenomenon attending the sounding of two notes at the same time, which approach within certain limits to the producing of a conchord with each other, which the late Dr Robert Smith, in his *Harmonics*, has applied, with the happiest effect, to the practical tuning of instruments, according to any given system or arrangement of the intervals. The phenomenon of beats forms also the means, by which practical tuners, unacquainted with theory or the exact comparative magnitudes of intervals, adjust the notes of organs, piano fortes, harps, &c. by the judgment of their ear, in the daily exercise of the tuning profession.

It seems, therefore, of the utmost importance for the

advancement of this sublime and beautiful science, to exhibit theorems for calculating the number of beats made in a given time, divested as much as possible of the difficulties likely to deter the practical tuner and musician from attempting to understand and apply them to use, illustrated by an example in each case. For the satisfaction of such as are unable or unwilling to go into the nice and difficult theory on which these theorems are founded, nothing is so likely to inspire confidence in their truth, as well as in the right application of the rules they furnish to particular cases they may undertake to calculate, as the having several such theorems, involving different data, yet by means of which the same results are to be obtained.

Of the five methods given below, for calculating the beats of any tempered conchord from different data, the two first only have hitherto been published, as far as we are acquainted; the first is the original method of Dr Smith, *Harmonics*, prop. xi.; and the second is that of Mr Emerson, *Algebra*, prob. ccii.

1st Method of calculating the Beats of an Imperfect Conchord.

Let the conchord, whose perfect ratio is expressed by $\frac{n}{m}$, (n being the *least* term of the ratio in its *lowest*

terms) be tempered by the fraction $\frac{q}{f}$ of a major comma, (q being the *least* term of this fraction;) also let M and N be the number of complete vibrations in one second of time, made or excited by the *acute* and the *grave* notes of the above tempered conchord respectively: and let b be the number of *beats* occasioned by this temperament in one second.

Then, if the temperament be *sharp*, or the chord *greater* than perfect,
$$b = \frac{2q \times m \times N}{161f - q} \text{ or } \frac{2q \times n \times M}{161f + q}$$

Or, if the temperament be *flat*, or the chord *less* than perfect,
$$b = \frac{2q \times m \times N}{161f + q} \text{ or } \frac{2q \times n \times M}{161f - q}$$

Example.

If the conchord proposed, be the minor sixth (CbA) of earl Stanhope's monochord system: here $\frac{5}{8} = \frac{n}{m}$ is the ratio of the perfect conchord, and (*Phil. Mag.* xxvii. 195.)

$\frac{21}{22} = \frac{q}{f}$ is the part of a comma nearly, (not $\frac{20}{21}$, as erroneously printed,) by which the same is flattened: also $N=240$, the number of complete vibrations of C , the bass note in 1st: and from the first of the lowest of the theorems above, we have
$$\frac{2 \times 21 \times 8 \times 240}{161 \times 22 + 21} = \frac{80640}{3563} = 22.6326,$$
 the beats in 1st.

2d Method.

Let the conchord, whose perfect ratio is expressed by $\frac{n}{m}$ (n being the *least* term of the ratio in its *lowest* terms) be tempered so that its *string*, which, for sounding the *treble* note of the perfect conchord was S in length, is altered to be s length: also let N be the number of complete vibrations in one second of time made

by the bass-note of the conchord; and let b be the number of beats occasioned by this temperament in one second of time.

Then, if the temperament be *sharp*,
$$b = \frac{S - s}{s} \times N \times m$$

Or, if the temperament be *flat*,
$$b = \frac{s - S}{s} \times N \times m$$

Example.

If the conchord proposed, be the minor sixth of earl Stanhope's monochord system: here $\frac{5}{8} = \frac{n}{m}$ is the ratio of the perfect conchord, and (*Phil. Mag.* xxvii. 196, and xxx. p. 1.) $S=625$, and $s=.6324554$, are the lengths of string for sounding this perfect and tempered conchord with the bass-note = 1, respectively: also $N=240$, the vibrations of C the bass-note in 1st, and from the second theorem above, we have

$$\frac{.6324554 - .625}{.6324554} \times 240 \times 8 = \frac{14.314368}{.6324554} = 22.6330,$$
 the beats in 1st.

Corollary. If in this method, the bass-note be considered as unity, then $S = \frac{n}{m}$, and our theorems become,

For *sharp* temperaments,
$$b = \left(\frac{n}{s} - m \right) \times N$$

For *flat* temperaments,
$$b = \left(m - \frac{n}{s} \right) \times N$$

And the above example will stand thus; viz.

$$\left(8 - \frac{5}{.6324554} \right) = 240 = .094306 \times 240 = 22.6334,$$
 the beats in 1st.

3d Method.

Let the conchord whose perfect ratio is expressed by $\frac{n}{m}$, (n being the *least* term of the ratio in its *lowest* terms,) be tempered by l logarithms, (of seven places, wherein 1.0000000 expresses the key, and .6989700 the octave :) also let M and N be the number of complete vibrations in one second of time, made or excited by the *acute* and *grave* notes of the above tempered conchord respectively; and let b be the number of *beats* occasioned by this temperament in one second.

Then, if the temperament be *sharp*,
$$b = \frac{2l \times m \times N}{8686000 - l} \text{ or } \frac{2l \times n \times M}{8686000 + l}$$

Or, if the temperament be *flat*,
$$b = \frac{2l \times m \times N}{8686000 + l} \text{ or } \frac{2l \times n \times M}{8686000 - l}$$

Example.

If the conchord be the minor sixth of earl Stanhope's monochord system: here $\frac{5}{8} = \frac{n}{m}$ is the conchord, and (*Phil. Mag.* xxvii. 195.) $l =$ a *flat* temperament of 51500 in seven place logs. Also $N=240$, the vibrations per 1st: and from the first of the lower theorems, we have

$$\frac{2 \times 51500 \times 8 \times 240}{868600 + 51500} = \frac{197760000}{8737500} = 22.6335,$$
 the beats in 1st.

4th Method.

Let the conchord whose perfect ratio is expressed by $\frac{n}{m}$ (n being the *least* term of the ratio in its *lowest* term,) be tempered so that its *acute* and *grave* sounds make M and N complete vibrations in one second of time, respectively; and let b be the number of *beats* occasioned by this temperament in one second of time.

Then, if the temperament be *sharp*, $b = nM - mN$.

Or, if the temperament be *flat*, $b = mN - nM$.

Example.

If the conchord be the minor sixth of earl Stanhope's monochord system, here $\frac{5}{8} = \frac{n}{m}$ is the conchord, and (*Phil. Mag.* xxx. p. 5.) $M = 379.47$ and $N = 240$ are the vibrations respectively; and from the second of the above theorems we have,

$3 \times 240 - 5 \times 379.47 = 1920 - 1897.35 = 22.65$ the beats in 1".

5th Method.

Let the conchord, whose perfect ratio is expressed by $\frac{n}{m}$, (n being the *least* term of the ratio in its lowest terms) be tempered by r *Schismas* (Σ in the Table, Plate XXX.), neglecting the smaller intervals most *minute* (m) and lesser *fraction* (f), should they occur, and if great accuracy is sought, substituting their value in decimals of Σ : also let M and N be the number of complete vibrations in one second of time made by the *acute* and *grave* notes of the above tempered conchord, respectively; and let b be the number of *beats* occasioned by this temperament in one second.

Then, if the temperament be *sharp*, $b = \frac{2r \times m \times N}{1772 - r}$, or $\frac{2r \times n \times M}{1772 + r}$.

Example.

If the conchord be the minor sixth of earl Stanhope's monochord system, here $\frac{5}{8} = \frac{n}{m}$ is the conchord; and (*Phil. Mag.* xxviii. 141.) $r =$ a flat temperament of 10.5 schismas; and $N = 240$, the vibrations of the bass per second: and from the first of the lower theorems above we have, $\frac{2 \times 10.5 \times 8 \times 240}{1772 + 10.5} = \frac{40320}{1782.5} = 22.6199$, the beats in 1".

Note. $.0078631 \times \Sigma = m$, and $127.1905 \times m = \Sigma$; also $.149661 \times \Sigma = f$, and $6.5297 \times f = \Sigma$. The near coincidence of the above six results would have been still more complete, but that the first, third, and fifth methods are founded on approximating theorems, and the vibrations M , used in the fifth method, are not given to places enough of decimals to insure a result equally accurate with the other calculations.

By two, at least, of the above methods, the beats produced by every conchord, throughout several tempered systems, have been calculated, and will be given in Tables, under the names of those systems, or that of their respective authors, as HAWKES, SMITH, STANHOPE, YOUNG, &c.; reserving an account of such systems as

may come to our knowledge, but under no well-known name, for the article TEMPERED SYSTEMS of Music, wherein we shall endeavour to draw some comparisons between the different systems of temperament, whose correct results will thus be exhibited, in a form perfectly adapted for comparing their respective merits: and, we propose, to aid these comparisons, by some new and general investigations, on the relations subsisting between the temperaments of the different conchords, in every *donzeave*, or tempered system of twelve intervals, only within the octave. (g)

BEATON, or BETON, DAVID, archbishop of St Andrews, primate of Scotland, and cardinal of the Romish church, the son of John Beaton of Balfour, in Fife, was born in 1494. He was educated at the university of St Andrews, and gave early indications of strong mental powers. Being destined for the church, he was sent, by his uncle, the archbishop of St Andrews, to complete his education at the university of Paris; and, as soon as he attained the usual age, he was admitted to holy orders. In France he was early received into the favour and service of the duke of Albany, regent of Scotland, during the minority of James V.; and, by him, in 1519, he was appointed resident at that court. About the same year, his uncle bestowed upon him the rectory of Campsie; and, in 1523, vested him with the abbacy of Aberbrothock. He returned to Scotland in 1525, and received the privy-seal in 1528. In 1533, we find him, in conjunction with sir Thomas Erskine, returning to France, to confirm the treaty entered into between the two nations, and to demand in marriage for his sovereign the daughter of the French king. During his residence at that court, he insinuated himself into the good graces of Francis; was favoured with a knowledge of the whole political system of that great monarch; and, by his influence in bringing over his sovereign to adopt the same political views, he laid the foundation of his own future greatness. The nuptials of the Scottish king and the young princess, were celebrated at Paris, on the 1st of January 1537; and Beaton returned with them to Scotland in the ensuing May; but the queen having survived her marriage only two months, he was again sent to Paris, and successfully negotiated a second marriage for the king, with Mary, daughter of the duke of Guise.

Beaton, now high in power, and eminently qualified to promote the interests of the church of Rome, was, in 1538, raised by Pope Paul III. to the rank of cardinal, by the title of St Stephen, *in monte calio*. This promotion gave great uneasiness to Henry VIII., who, jealous of Beaton's growing ascendancy over his sovereign, and afraid of the consequences of that strict alliance which he had formed with the king of France, devised a scheme for the cardinal's disgrace; but, though deeply laid, it did not succeed. The archbishopric of St Andrews falling vacant, the cardinal succeeded, and became primate of Scotland. No sooner was he invested with that high office, than he discovered the most violent spirit of bigotry and persecution. Having summoned a numerous meeting of the Romish clergy and laity to St Andrews, he, in a long speech, denounced the reformers, who, he said, openly maintained their heretical opinions in the king's court. He particularly accused Sir John Borthwick, whom he had cited to that meeting; and against whom a sentence of excommunication for non-appear-

* If very great exactness is required, 1772.243 may be used instead of 1772

ance was passed, his goods confiscated, and his person burned in effigy. But Borthwick was not the only victim of Beaton's resentment; several persons of rank and distinction were included in this prosecution, among whom we find the celebrated Buchanan. All would, without doubt, have suffered death, had they not happily escaped from prison; and to what length this bloody persecutor would have gone, it is impossible to say, had not the king's death put a stop to his power; for, it is affirmed, that he had furnished his majesty with a list of no fewer than 360 of the nobles, whom he represented as heretics, who deserved to suffer the severest punishment. James appears not to have been averse to those violent measures, being tempted by the hope of getting the valuable estates of the convicted nobles annexed to the crown.

When the king died, Beaton produced a deed signed by his majesty, which Buchanan affirms was forged. The fact is also admitted by Robertson and Guthrie. Hume, after mentioning it, expresses himself thus: "At least, (for historians are not well agreed in the circumstances of the fact), he had read to James a paper of that import, to which that monarch, during the delirium which preceded his death, had given an imperfect assent and approbation." The deed established the regency in himself, and the Earls of Argyle, Huntly, and Arran; but it was set aside, although to give it validity, he caused it to be proclaimed at the cross of Edinburgh. The Earl of Arran, who, next to the young princess, was heir to the crown, was chosen sole regent, during her minority; and the cardinal was sent prisoner to the castle of Blackness. But he found means of soon obtaining his liberty, and of restoring himself to the good opinion of the regent: nay, he was again admitted to the council; promoted to the high office of chancellor of the kingdom; and, at the express solicitation of the regent himself, received a commission from the Pope, appointing him his legate.

Having obtained this new dignity, he lost no time in using it for the interest of the Romish see: he commenced a severe prosecution against the reformers; and he had the address to prevail upon so many persons, of the highest rank in the kingdom, to sit in judgment with him, that the condemnation of these innocent men had more the appearance of being their act than his. Following out the same arbitrary proceedings, he summoned, in 1546, an assembly of the clergy at Edinburgh, and hearing that the celebrated protestant preacher, Mr. George Wishart, was then officiating in that neighbourhood, he procured an order from the governor to have him apprehended, and sent first to the castle of Edinburgh, and afterwards to the castle of St Andrews. Having got him in his power, he found no difficulty in procuring a sentence of an assembly of prelates to condemn him to the flames. On the 2d day of March 1547, he suffered the execution of the sentence, with a faith and fortitude worthy of a Christian martyr; while his barbarous persecutor, from a window in the castle of St Andrews, feasted his eyes with the shocking spectacle. Buchanan relates, that Wishart, while wrapt in the scorching flame, foretold the death of Beaton in these remarkable words, "He who looks down upon me from yonder lofty place," pointing to the cardinal, "shall ere long be as ignominiously thrown down, as now he proudly lolls at his ease." But Knox, in his History, assigns several good reasons for not giving credit to that prediction. Admitting the fact, it may be viewed not as a

prophecy, properly so called, but as a denunciation of the divine vengeance on the cardinal for his iniquities. Wishart could not be ignorant of the general odium in which Beaton was held, and might very naturally believe, that he would soon fall a victim to his own arrogance and cruelty. Relying, however, on the power of the nobles, and the attachment of the Romish clergy, Beaton appeared perfectly indifferent to the sentiments of the great body of enemies, whom that inhuman deed had raised against him.

Not long after, he went to Finhaven, the seat of the Earl of Crawford, where he solemnized, with great pomp, a marriage betwixt the eldest son of that nobleman and his own natural daughter: a proof of the high reputation in which he was at that time held among the nobility of Scotland. The marriage-contract, subscribed with his own hand, is still extant; and the fortune he gave her amounted to 666*l.*: 13*s.*: 4*d.* sterling, a very considerable sum in those days. Having received intelligence, that an invasion was threatened by an English squadron, which was seen upon the coast, he hastened back to St Andrews, and fortified his castle. While thus employed, Norman Lesley, eldest son of the Earl of Rothes, was treated by him with great injustice and contempt. His uncle, Mr John Lesley, a violent enemy of the cardinal, eagerly seized this opportunity of inflaming his nephew; and having conferred with some others, to whom he was equally obnoxious, it was resolved that he should be cut off. Having met by appointment at St Andrews, early on the morning of the 29th May 1546, they seized the porter, and secured the gates of the castle; and, although they did not exceed sixteen, they turned out all the workmen and servants, to the number it is said of 150, with so little noise that the cardinal was not awaked till they approached the door of his chamber, which he immediately secured. Being prevailed upon to open it, by a promise, that no violence should be offered to his person, they rushed in with drawn swords, and put him to death. His body, it is said, was shown to the populace at that window from which he had lately, with a barbarous joy, beheld the death of the innocent Wishart.

Thus fell this eminent prelate, who was not more distinguished by his rank, than odious by his vices. Endowed with great abilities, he raised himself to the highest station; but his ambition was unbounded, and his pride insupportable. He was the favourite of the regent, Duke of Albany, and of James V.; and so entirely did he gain the confidence of every person whom he served, and so artfully did he manage his ascendancy over them, that his own influence was never diminished. Bred to business, he was but little acquainted with the learning and controversial writings of the age; but he had studied politics at the court of France, and was well acquainted with the temper and influence of all the nobility of his own country. He took into his own hands the management of the affairs of the kingdom, both civil and ecclesiastical; and he often treated the ambassadors of foreign states with all the supercilious demeanour of an arbitrary monarch. Bent upon the execution of all his schemes, he scrupled not by what means he gained his end; and he frequently sowed the seeds of discord among his enemies, that he might reap security from their dissensions. Devoted to the church of Rome, he promoted her cause by the most cruel and sanguinary measures; and though the manner of his death cannot be justified, it spread an universal joy among all the friends

of the reformation. He amassed great wealth, which he bequeathed to his natural children. To each of his three sons he left a valuable estate, and his three daughters obtained marriages in three families of distinction in Scotland. Had his virtues been equal to his abilities, and his life suitable to his high rank, he would not have fallen by the hand of an assassin, nor would his character have stained the page of history. He is an eminent instance of the union of great talents with great vices; and his life, as well as his death, may teach a valuable lesson to mankind. See Buchanan's *Hist. lib. xiv, xv*. Robertson's *Hist. vol. i. p. 96. Biograph. Britannica, vol. ii. p. 37.* (A. F.)

BEATTIE, JAMES, an excellent poet and essayist, was born on the 5th of November 1736, in the parish of Laurencekirk, Kincardineshire, Scotland. His father kept a small retail shop in the village of that parish, and at the same time rented a small farm in the neighbourhood, in which his forefathers had lived for many generations. The poet's mother was left a widow when young Beattie was only ten years of age: but the loss of a protector was happily supplied by his brother David, who sustained him in his school education, till he obtained, by his promising abilities, a bursary or exhibition at Marischal college, Aberdeen. Here he studied Greek under Professor Blackwell, author of two works, entitled, the *Court of Augustus*, and the *Life of Homer*: a man grievously infected with the pedantry of Lord Shaftesbury's style, but possessed of considerable learning, and meriting mention in Beattie's life as the first who encouraged his early genius. Having taken the degree of master of arts, at the end of four years attendance at the university, our poet filled the humble situation of schoolmaster in the neighbouring parish of Fordun. His employment here did not preclude him from that slight attendance to the study of divinity which the preparation for holy orders requires in Scotland, nor from occasionally cultivating his muse. Never did poetical talent ripen so slowly as with Beattie. Till the age of 25 he wrote indifferent verses; and within ten years from that period, he was, excepting Goldsmith, the purest and most majestic poet of his own time. Yet his early and indifferent productions, which he transmitted to the Scottish Magazine, gained him a little local celebrity. Mr. Garden, a Scottish lawyer of some taste and ingenuity, afterwards Lord Gardenstone, and at that time sheriff of Kincardineshire, afforded him a sort of patronage, and introduced him to the tables of the gentry in that neighbourhood; an honour not often extended to the humble teacher of a parish school. In 1757, a vacancy occurred in the grammar school of Aberdeen, and Beattie stood competitor. He was foiled by a candidate who surpassed him in the minutiae of Latin grammar, but though unsuccessful, he retired without disgrace; and a vacancy in the same school soon after occurring, he was appointed successor without a trial. In this new situation his reputation extended with the sphere of his acquaintance; he became known by his conversation and talents, among a discerning community; and at 24 years of age, we find him obtaining, through the reputation of those abilities, the professorship of moral philosophy in the Marischal college of Aberdeen; a place in which he became the associate of such eminent men as Dr Reid, Dr Campbell, and Dr Gregory, who then graced the university. In 1760, he published a small collection of poems, the most of which he was afterwards ashamed to print, in company with his

Minstrel. He actually bought up and destroyed as many copies as he could find of this unhappy volume in the days of his established fame. In 1763, he made his first visit to London, but he seems at that time to have been unnoticed and unknown. In 1766, he married a Miss Dunn, a woman of some beauty and accomplishments, but with whom his union proved an abundant source of domestic misery—the dreadful malady of an hereditary madness, which at last made it necessary to confine her, for a long time showed itself equivocally before it came to a crisis, in the caprice of her dispositions, and the inquietude of her temper. In 1770, he published his *Essay on Truth*; and in the following year, the first part of his exquisite poem the *Minstrel*.

During the summer of the latter year he paid a second visit to London, which he renewed in 1773. During this last visit he was made a doctor of laws by the university of Oxford, and obtained the king's warrant for a pension of 200*l.* a-year. The honours which were paid to him during this year, made it, at least in his own opinion, the most distinguishing era of his life. He was courted by peers and bishops as the most able champion of truth. The English churchmen and the orthodox gentry had been long indignant at the writings of Hume and the Scottish sceptics, and zealously applauded an antagonist who had understood or answered Hume no better than themselves. It did not occur to those pious people, that the scepticism which Beattie had answered by abuse and apostrophes, related to abstract questions wholly inapplicable to practical virtue or vice; and they forgot that Berkeley, at least as good a Christian as any of themselves, had gone half way in the very scepticism which Hume inculcated. Dr Reid, who has combated Hume with the hard sinews of argument and metaphysics, was not half so popular a champion to the church and lay alarmists at infidelity. He was not pathetic, outrageous, or abusive, and he required the trouble of thinking and study to follow him; a pain which is wholly spared to the readers of Beattie's *Essay on Truth*. At this flattered period of his life, Beattie was introduced to their majesties at Kew, and spent an hour in familiar conversation with them. The king congratulated him on having refuted Hume, and ruined the sale of his book. In the aristocracy of literature, however, kings themselves have no power of conferring rank; and while we admire a venerable sovereign encouraging and communing with an amiable man of letters, yet when we hear it announced in the royal closet, that Mr Hume's publishers had been hurt by the writings of Beattie, we are apt to call to mind how seldom kings are told the truth. To have sunk the poet in the philosopher, in commending him, seems to be absolute satire. Yet though much of Beattie's splendid reception among the peers and bishops, was owing to his over-rated merits as a metaphysician, there was much of it also due to his amiable manners and his genius.

At the end of the year 1773, there was a proposal for transferring him to a professorship in the university of Edinburgh, which he declined. The reason which he assigns in one of his letters, was the fear of hostility from his infidel enemies; a reason which has been exposed very severely in a harsh review of his life. There may be something in this declaration of the soreness respecting his literary opponents, which was certainly a weakness in Beattie; but there is nothing in it worthy of serious reproach. The disciples of the sceptical philosophy are not entirely exempt from the human weak-

ness of hating their literary antagonists; and if Beattie dreaded to encounter that spirit in Edinburgh, we need not wonder at his preferring to remain amidst the congenial orthodoxy of Aberdeen, rather than to trust himself among strangers, nor at his giving the reason for it in a confidential letter. His refusal of a living in the church of England, proffered to him by Dr Porteous in 1774, was dictated by disinterested motives, which have never been called in question. After this, there is little incident in his life. He published one volume of Essays in 1776, and another in 1783; a little treatise on the Evidences of Christianity, in 1786; and the outline of his Academical Lectures in 1790. In the same year he edited at Edinburgh Addison's papers, and wrote a preface. He was very unfortunate in his family. The situation of his wife precluded him from the enjoyment of visitors in his house, at the time when his increased circumstances would have allowed him to exercise a limited hospitality. The loss of his son, James Hay Beattie, a young man of highly promising talents, and who had been actually conjoined with him in the professorship, was the greatest, though not the last, calamity of his life. He made an effort to relieve his spirits by another journey to England, and some of his letters from thence bespeak a temporary composure and cheerfulness; but the wound was never healed. Music was one of the great solaces of his leisure hours; but from that solace he was cut off by the overwhelming associations which were excited by the amusement which his son and he had shared in common. At the end of six years, his second son, Montague Beattie, was also snatched from him in the flower of manhood. This crowning misfortune appears to have wholly crushed his spirits. With his wife in a madhouse, his sons dead, and his health broken, he might be pardoned for saying, whilst he looked upon the corpse of his youngest child, "I have done with this world." He acted indeed as if he had felt so; for although he performed the duties of his professorship till within a short time of his death, he applied to no study, enjoyed no society or amusement, and answered but few letters of his friends. Yet, amidst the depth of his regret, he would sometimes express an acquiescence in his childless fate. "How could I have borne," he would say, "to see their elegant minds mangled with madness?" A palsy, which struck him in 1799, terminated his sufferings, after repeated attacks, in 1803. "His person," says a writer of his life in the Annual Register for 1805, "was of the middle size, of a broad square make, which seemed to indicate a more robust constitution than he really had. He was all his life subject to headaches, which, on many occasions, interrupted his studies. His features were exceedingly regular; his complexion somewhat dark; his eyes had more expression than those of any person I ever remember to have seen."

Beattie's Philological and Critical Essays are the most pleasing of his prose works. As a critic, he has been preferred to Blair, by the poet Cowper. Without the severe and chaste dignity of Blair's prose, he is more animated, more diffusive and unequal, more illustrative and more entertaining. His constitution as a poet spoilt him for a metaphysician, and his moral philosophy did no good to his poetry. In his *Essay on Truth*, he rails at the sceptics in rhapsodies and apostrophes, as if he could exorcise the hard-hearted spirits

of metaphysics by anathemas, or untie the knot of paradoxes by cursing the hand which had tied them. On the other hand, he loads the beautiful poem of *The Minstrel*, with explanations on free will and providence. A shepherd's son, and a mountain minstrel, listens to the hermit's discourses, as if he were training for a chair of moral philosophy; and comes to have his doubts cleared up, upon the moral disorder of the world, at a time of life when the genuine minstrel is more apt to be troubled with doubts about the fidelity of his mistress. If the character of Edwin was too refined and elevated to be displayed in the tender passion, he might have discoursed with the hermit on subjects more congenial to the poetical character than these sombre discussions.

The true character of poetical genius is in love with the wild and the wonderful; it has nothing to do with abstract views of nature, or moral actions; it believes and enjoys implicitly, and delights neither in creating nor resolving doubts. The actual enjoyments of the poet are inimitably portrayed in the first part of the *Minstrel*; in the second part we leave him to the study of ethics, with as little interest as if he were discoursing with Adam Smith on the wealth of nations, or with Malthus on the checks to population. Yet the moral tenets in the second part, though inaptly placed, are elegantly delivered. The first part of the *Minstrel* is a gem of the purest water; Edwin's character is a most interesting portrait of moral beauty, supported without the aid of drama, dialogue, or action; yet as finished, distinct, and original, as a dramatic or epic action could have made it. It is wonderful, at the end of sixty stanzas, to find what a new, yet recognizable being we have been made acquainted with,—a being so unlike the world, and yet so natural. The writer who described Edwin might well felicitate himself, in the words of the French poet:

———heureux le génie

Qui ———
Sans masque, sans cothurne et sans illusion,
D'un style simple et vrai fait parler la raison.
Il n'entend pas pour lui retenir le théâtre
Des suffrages bruyants d'une foule idolâtre:
Mais le sage le lit. Le sage quelquefois
Pour rêver avec lui, s'enfonce dans les bois,
Et, charmé de ses vers, n'en suspend la lecture
Que pour voir les forêts, les cieux et la nature.

DE LILLE sur l'Imagination.

The particular and minute beauties of this popular poem we need not trouble our readers with pointing out. Its general characteristic merits are, an unaffected elevation and sweetness of sentiment, terse and comprehensive description of rural scenery, and a style of pure and transparent simplicity. The beauty of external nature was never more finely worshipped than in the conclusion of the ninth stanza, which Gray so truly pronounced to be inspired: "Oh! how canst thou renounce, and hope to be forgiven." Dr Aikin, with his usual coldness as a critic, has objected to the fairy vision of Edwin as too splendid and artificial for the fancy of an untutored youth. This is a most absurd objection. If we suppose Edwin to have lived in minstrel days, untutored as he was, he must have heard the ballads of his country; and in these there is sufficient mention of all the materials which constitute his dream. The description of Edwin's walks, and of the hermit's valley

in the second book, are perhaps the very finest poetical paintings of landscape which our language possesses. (z)

BEAUMARIS, or BEAUMARSH, the principal town of the isle of Anglesea, in South Wales, is situated at the north entrance of the Menai strait, which forms here a spacious bay. The town, which is extremely neat, has two large streets, which contain 267 houses, a handsome church adorned with a lofty square tower, and an elegant and commodious town-hall. A free grammar school, and eight alms-houses, evince the charitable disposition of the inhabitants. But the most remarkable object at Beaumaris is its castle, to which the town originally owed all its importance, and probably its existence. When Edward I. had subjugated Wales, he found it necessary to erect fortresses in different places, to overawe the inhabitants, whose spirit, still unbroken and extremely impatient of the yoke, panted for an opportunity of regaining their independence. Magnificent castles had already been reared in Caernarvon and Conway; and the insular situation of Anglesea rendered it still more necessary to have it commanded by a fort and an English garrison. Accordingly, in the year 1275, the foundation of a castle was laid in a place called Bonover Marsh, which afterwards received the French appellation *Beaumarais*, or beautiful marsh. Its situation enabled the engineers to surround this castle with a ditch, which might constantly be filled with water from the bay; and to cut between the river and the castle a canal by which small vessels might convey their cargoes up to the very walls. When this castle was completed, it was garrisoned by twenty-four soldiers, and entrusted to a governor, who was also made general of the town. As this fortress became extremely oppressive to the town, many contentions arose, and several bloody encounters took place between the inhabitants of the town and the soldiers. One of these encounters, called the black-fray, which happened in the reign of Henry VI. was attended with great slaughter. The insolence both of the governors and the soldiery, in all these Welsh garrisons, was indeed intolerable. Their general object was to exclude the native inhabitants from the towns dependent on their fortresses; and so far had they succeeded in Anglesea, that in a rental of the borough property of Beaumaris, taken so late as 1608, there appear only seven Welsh names, and one burgage in the tenure of a Welshman. In the turbulent reign of Charles I., the gentlemen of Beaumaris and Anglesea, animated with the warmest loyalty, determined to oppose the parliamentary forces which had assembled at Conway, and had deputed five commissioners to manage their business. But their loyalty was of no avail against the superior discipline and courage of their antagonists. They were routed and dispersed in every direction; and on the 2d of October 1648, the town and castle surrendered to general Mytton, and the inhabitants came under an obligation to pay to their conquerors the sum of seven thousand pounds within fourteen days. This castle, which is now the property of the crown, stands on the grounds of lord Bulkely. It is attached to the east end of the town, and covers a considerable space of ground. Part of it lies in ruins; but its outer walls, several towers, and many other parts, still remain to mark out its dimensions, and to shew the style of its architecture.

Beaumaris cannot boast of great antiquity. Before the erection of the castle, it seems to have been an ob-

scure, insignificant place. Edward I. surrounded it with a wall, made it a corporation, and endowed it with some privileges. Since the time of Edward VI., it has regularly been represented by one member in parliament, the right of electing whom is vested in the mayor, bailiffs, and capital burgesses only, amounting to twenty-four in number. This is the only place in Wales where the right of election is confined to the corporation. The government of the town is entrusted to the mayor, two bailiffs, and the capital burgesses, whose number is limited to twenty-one; to the number of ordinary burgesses no limits are set. Beaumaris is distant 254½ miles N. W. from London. Population 1576. N. Lat. 53° 14', W. Long. 4° 15'.

The bay of Beaumaris is a very fine bason, in which ships can ride safely at anchor, in six or seven fathoms water, even at ebb tide. Between Aber and Beaumaris, the distance is four miles broad, though the sea, at low water, fills a channel of not more than one mile. The remainder is one bed of sand; and the roots of oak trees, found at a considerable distance from the present shores, sufficiently prove that the sea has here made great encroachments, and that these beds were formerly soil quite free from water. See Mr Pennant's *Tour in Wales*. Bingley's *Tour round North Wales*. (u)

BEAUNE, the second town in the department of the Cote D'Or, situated at the foot of a hill on the river Bourgeoise. The town, which is of an oval form, and stands on calcareous ground, has handsome houses and wide streets, and is well situated for inland trade. The new gate is a specimen of good architecture. The church of St Peter is a handsome building; but the most beautiful and magnificent edifice is the hospital, which was founded in 1443 by Nicholas Rollin, chancellor to Philip duke of Burgundy. The castle of Beaune is now in ruins. An account of the curious quarrel between the inhabitants of this town and the celebrated wit Piron, will be found in Millin's *Travels through the Southern Departments of France* in 1804 and 1805, chap. x. Population 8344. (j)

BEAUSOBRE, ISAAC DE, an eminent French protestant divine, was born at Niort in Switzerland,* on the 8th of March 1659. Little is known of his ancestors, but that they were originally from Provence, and had taken refuge in Switzerland from the massacre of St Bartholomew. From his tenderest years Beausobre displayed a magnanimous superiority to the feelings of avarice and ambition. He might have entered upon life with the fairest prospects of opulence and honours; for a cousin-german of his father, who was nearly related to Madame de Maintenon, strongly urged him to study law, that he might present him to that lady, and thus insure his future fortune. But Beausobre, who had still more exalted views, resisted all his solicitations, and resolved to devote himself to the sacred ministry. After studying divinity at the college of Saumur, he was ordained at the age of 22 years, and appointed to the charge of a protestant congregation in some part of France. He had not been above three

* There is no town of that name in Switzerland. The city of *Niort*, where Beausobre was born, is now the chief place of the department of the two Sevres, a part of the late province of Poitove, in France. See the *Nouveau Dictionnaire Historique, par une Société de gens de Lettres*. DU PONCEAU.

years in that office, when a violent persecution arose against the protestants, and his church was ordered to be shut up. With a zeal, natural to his age, but extremely imprudent, he opposed the orders of the court, and broke the royal seal, which had been affixed to the door of his church. Being condemned to make *amende honorable* for this offence, he was forced to conceal himself, till he had an opportunity of leaving France.

His first intention was to seek an asylum in England, but particular circumstances afterwards determined him to go to Holland. There he became known to the Princess of Orange, who could well appreciate his merits, and thought herself fortunate in getting him appointed chaplain to her daughter, the Princess of Anhalt Dessau. In this capacity he repaired to Dessau in 1686. The happiness which he enjoyed in this retreat, made him ample amends for the loss of his country. The Princess of Anhalt, a lady of great accomplishments, honoured him with the fullest confidence; and he was enabled to pursue his studies without disquiet or interruption. It was here he published his first work, entitled, *A Defence of the Doctrine of the Reformed*, occasioned by the circumstance of a prince of the house of Saxony having changed his religion. It was printed at Magdeburg in 1693, and though the typography was extremely bad and incorrect, the book was very favourably received.

Next year, (1694,) he was induced, by the advantages which the French refugees enjoyed in Brandenburg, and the facilities which Berlin afforded for study, and for the education of a family, to repair to that city, in which he continued to reside during the remainder of his life. At first he was enrolled among the number of ordinary pastors, who ministered in the parishes granted by the court to the refugees. But his talents soon raised him to higher employments. He was made chaplain to their majesties, counsellor of the royal consistory, director of the French house, inspector of the French college; and, a year before his death, was appointed superintendent of the French churches in Berlin, and of the towns comprehended in that diocese. While he discharged with the highest honour to himself the duties of these several offices, he at the same time pursued his studies with unwearied assiduity. The first work which he undertook, was a *History of the Reformation*, which occupied him for upwards of forty years. He left it in manuscript ready for the press, and it was published at Berlin in 1734 and 1735. This work, of which the principal object is to trace the origin and progress of Lutheranism, contains some very curious details relative to the diffusion of protestant principles in France and Switzerland, and the characters and writings of those who were most active in opposing or defending the reformed religion. He was employed, along with his colleague L'Enfant, by the court of Berlin, in translating the New Testament into French. St Paul's Epistles fell to the share of Beausobre, and the work, which was published in 1718, with an ample preface and notes, was very favourably received. He was one of the principal members of the Anonymous Society in Berlin, and had the direction of the *Bibliothèque Germanique* till his death. To that journal he contributed several papers. While engaged in composing the *History of the Reformation*, he was led into a digression on the *History of Manichæus and Manichæism*, which, swelling far beyond the bounds within which he originally intended to confine it, was published as a separate work

in two volumes 4to. This is by far the most elaborate and esteemed of his writings; and has drawn forth the warm commendations of Gibbon and Lardner, who were of all men the best qualified to judge of its merits.

No man ever possessed a happier combination of the talents necessary to a preacher than Beausobre. His sermons were distinguished by a fire of imagination, a richness and elegance of diction, an originality of thought even on the most common topics, and a felicity of illustration, which have seldom been surpassed. His elocution, naturally easy and graceful, was aided by the advantages of a most engaging countenance, a noble figure, and a graceful air. And his instructions, flowing warm from his heart, were recommended and enforced by the bright example of a life actively employed in the exercise of every Christian virtue. He died on the 5th of June 1738, at the age of eighty years; retaining to the last the possession of his faculties, and the full relish of life. See *Memoire sur la Vie de Beausobre*, prefixed to the 2d vol. of his *Hist. du Manichæism*. (k)

BEAUTY, in its most general sense, denotes, any quality, or assemblage of qualities, in objects, which are calculated to excite in the observer, emotions of delight and complacency. In a more limited and appropriate sense, beauty is restricted to those qualities of objects which excite in the mind a species of tenderness, fondness, or affection. The great latitude with which the term has been employed, involves the analysis of the beautiful in a considerable degree of difficulty and obscurity. Thus we not only speak of a beautiful woman, and a beautiful flower, in which cases we employ the term in its most appropriate sense; but we speak also of a beautiful building, a beautiful piece of music, a beautiful poem, a beautiful machine, a beautiful theorem in geometry, or a beautiful trait of human conduct; examples of excellence involving qualities of extremely different kinds. A similar ambiguity exists in the terms significant of beauty in every known language. In Greek *το καλον*, or the epithet *βαυυφυ*, was as frequently applied to moral excellence as to the merely pleasing in objects; and in Latin, *fulchrum* had the same ambiguity, as we learn from its being so commonly conjoined with *honestum*.

In the observations which are to follow on this subject, we shall first inquire into the nature of these qualities which constitute beauty, strictly so called; and then we may perhaps be able to ascertain the origin of that analogical application of the term, by which it is made to characterize a class of objects so extremely different from each other as those to which it is applied in the vague and ordinary usage of language. Beauty, strictly so called, we have said, denotes those qualities of objects which excite in the mind a species of affection or tenderness. Even in this limited sense of the word, it comprehends qualities which are exceedingly various and diversified. There is not only a beauty of forms and of colours, but there is a beauty of motions, and a beauty of sounds. There is a beauty too, it may be said, though doubtless of a more debased and sensual kind, which is addressed to the smell, the taste, and the touch. And there is not only a physical beauty, or a beauty in the qualities of material objects, but there is a moral beauty; a beauty in the sentiments and dispositions of the human mind, by which affection is more powerfully roused than by any combination of merely physical properties.

Much ingenuity has been exercised in the attempt to determine in what all these various qualities agree, or to assign the true *theory of the beautiful*; a subject no doubt of considerable curiosity and interest. The ancients, indeed, have left us very little explicit on the philosophy of beauty. Plato has two dialogues on the beautiful; but in neither of them does he attempt to explain in what it consists, unless by mentioning in general, symmetry and proportion as its constituent qualities. Cicero, in the same indefinite manner, speaks of order and correspondence of parts as qualities of beautiful objects; but he gives no illustration of his doctrine, nor does he represent it as by any means complete.

Before descending to the systems of the moderns, we may mention the theory of the venerable father Augustine, who, in the fourth book of his *Confessions*, speaks of two or three treatises which he had written, in his younger days, concerning beauty; but some way or other he had lost them, and he does not appear anxious that they should ever be recovered. According to his view of the subject, which may be collected from other parts of his writings, beauty consists in unity of parts, or in perfect symmetry.* “And,” adds the father, “because all bodies upon earth are made of various elements, we are not here to look for perfect beauty, which is to be found alone in the one all perfect Supreme Being. But surely a rose has much less unity of parts than a ground worm; although the former is beautiful, the latter altogether disgusting.”

The theory which resolves beauty into a certain symmetry and determinate proportion of parts, and which seems to have been that entertained by the Greek and Roman philosophers, has had many strenuous advocates among the moderns, particularly in the class of artists, who seem to have thought that the constituent elements of the beautiful might be with certainty detected, and even measured in the most approved models of statuary and painting. The insufficiency of this theory has been very satisfactorily proved by Mr Burke, who is very decidedly of opinion, that “beauty is no idea belonging to mensuration; nor has it any thing to do with calculation and geometry.” To establish this opinion, he examines beauty, as it appears in vegetables, in the inferior animals, and in man; and in all these cases he finds that there are no certain measures on which the beautiful can be said, in any degree, to depend.

In the vegetable creation, we find nothing so beautiful as flowers; but flowers are almost of every sort of shape and arrangement; and are turned and fashioned into an infinite variety of forms. What proportion do we discover between the stalks and the leaves of flowers, or between the leaves and the pistils? How does the slender stalk of the rose agree with the bulky head under which it bends? The flower of the apple, on the other hand, is very small, and grows upon a large tree; yet the rose and the apple blossom are both beautiful, and the plants that bear them are most engagingly attired, notwithstanding this disproportion: What, by general consent, is allowed to be a more beautiful object than an orange tree, flourishing at once with its leaves, its blossoms, and its fruit? but it is in vain that we search for any proportion between the height, the breadth, or any thing else concerning the dimensions of

the whole, or concerning the relation of the particular parts to each other.

That proportion has but a small share in the formation of beauty, is fully as evident among animals. Here the greatest variety of shapes, and disproportions of parts, are well fitted to excite this idea. “The swan,” remarks Mr Burke, “confessedly a beautiful bird, has a neck longer than the rest of his body, and but a very short tail: is this a beautiful proportion? we must allow that it is. But then what shall we say to the peacock, who has comparatively but a short neck, and a tail longer than the neck and the rest of the body taken together? Turn next to beasts; examine the head of a beautiful horse; find what proportion that bears to the rest of his body, and to his limbs; and what relations these have to each other; and when you have settled these proportions as a standard of beauty, then take a dog or cat, or any other animal, and examine how far the same proportions between the heads and their neck, between those and the body, and so on, are found to hold. I think we may safely say, that they differ in every species; yet that there are individuals found in a great many species so differing, that have a very striking beauty. Now, if it is to be allowed,” adds our author, “that very different, and even contrary forms and dispositions are consistent with beauty, it amounts, I believe, to a concession, that no certain measures operating from a natural principle, are necessary to produce it, at least so far as the brute species are concerned.” *Sublime and Beautiful*, Part iii. Sect. 3.

The idea that the beauty of the human species depends upon certain determinate proportions has been carried so far, that artists will tell us how many heads go to the length of the body, how many wrists to the neck, or how many noses to the face. But the diversity that takes place in their various estimates sufficiently shews the fallacy of their doctrine. Some hold a well proportioned body to be seven heads; some make it eight, while others extend it even to ten. If we examine the master pieces of ancient and modern statuary, we shall find them for the most part differing from these established rules, and also from one another in the proportions of their parts; while they differ no less from the proportions that we find in living men, of forms extremely striking and agreeable. “The Hercules, by Glicon,” says Mr Hogarth, “hath all its parts finely fitted for the purposes of the utmost strength the texture of the human figure will bear; the back, breast, and shoulders, have huge bones, and muscles adequate to the supposed active strength of its upper parts; but as less strength was required for the lower parts, the judicious sculptor, contrary to all modern rule of enlarging every part in proportion, lessened the size of the muscles gradually down towards the feet; and, for the same reason, made the neck larger in circumference than any part of the head; otherwise the figure would have been burdened with an unnecessary weight, which would have been a drawback from his strength, and, in consequence of that, from its characteristic beauty. These seeming faults, which shew the superior anatomical knowledge as well as judgment of the ancients, are not to be found in the leaden imitations of it near Hyde Park. These saturnine geniuses imagined they knew how to correct such apparent *disproportions*.” *Analysis of Beauty*, chap. ii.

* *Omnis bono pulchritudinis forma unitas est*

The doctrine that beauty consists in determinate proportions, seems to have been derived from architecture; it being found that dwellings are most commodious and firm, when thrown into regular figures, with parts answerable to each other. This idea was transferred to our old-fashioned gardens, where trees were turned into pillars, pyramids, and obelisks; hedges were formed into so many green walls, and walks fashioned into squares, triangles, and other mathematical figures, with the utmost exactness and symmetry. And thus it was thought, that if we were not imitating, we were at least improving nature, and teaching her to know her business. But nature has at last escaped from these fetters; and our gardens, if nothing else, declare our conviction, that mathematical ideas are not the true measures of beauty. Even in architecture it is not any determinate principles of proportion, so much as the notion of stability and commodiousness, and of the adaptation of the means to the proposed end, that fixes the form and measures of any particular building. Thus there is one proportion of a tower, another of a house, one proportion of a gallery, another of a hall, another of a chamber; and to judge of the proportions of each, we must first be acquainted with the purposes for which they were designed.

This leads us to notice that theory of the beautiful, which resolves it into the perception of utility, or of an object being well adapted to answer the particular end for which it was intended; a doctrine which has had no less general an extent than the theory of proportion. Utility, or fitness for some important purpose, is doubtless a quality in things which we always contemplate with complacency and approbation; but it is a quality which may very readily be discriminated from beauty. On this principle, as Mr Burke remarks, "the wedge-like snout of a swine, with its tough cartilage at the end, the little sunk eyes, and the whole make of the head, so well adapted to its offices of digging and rooting, would be extremely beautiful. The great bag hanging to the bill of a pelican, a thing highly useful to this animal, would be likewise as beautiful in our eyes. The hedgehog, so well secured against all assaults by his prickly hide, and the percupine with his missile quills, would be then considered as creatures of no small elegance. There are few animals," adds he, "whose parts are better contrived than those of a monkey; he has the hands of a man, joined to the springy limbs of a beast; he is admirably calculated for running, leaping, grappling, and climbing; and yet there are few animals which seem to have less beauty in the eyes of all mankind. I need say little of the trunk of the elephant, of such various usefulness, and which is so far from contributing to his beauty. How well fitted is the wolf for running and leaping! how admirably is the lion armed for battle! but will any one, therefore, call the elephant, the wolf, and the lion, beautiful animals? I believe nobody will think the form of a man's legs so well adapted to running as those of a horse, a dog, a deer, and several other creatures; at least they have not that appearance: yet, I believe, a well-fashioned human leg will be allowed far to exceed all these in beauty." Part iii. sect. 7.

Again, if, in our own species, beauty were annexed only to usefulness, men would be considered as much more lovely than women; and strength and agility would be considered as the only beauties. The stomach, the lungs, the liver, as well as many other parts of the body,

are incomparably well adapted to their purposes; yet they are far from having any beauty. A plough is a highly useful machine, and excellently adapted to its end; yet we by no means consider it as beautiful; while this term may be properly applied to some insignificant trinket of no value at all. When we examine the structure of a watch, and even come to know thoroughly the use of all its parts, we may indeed admit the fitness of the whole; but are far enough from perceiving any thing like beauty in the work; but if its case be curiously chased and engraved, it will excite in us a very lively idea of beauty, although this kind of ornament is not of the smallest use. It is plain, then, that it is not utility, or the fitness of an object to produce some important end, that constitutes beauty.

Somewhat allied to the theories already mentioned, is that which ascribes beauty to *perfection* in a particular kind or species; or to the exact conformity of an object to the generally prevailing character of the co-related objects. This theory has been adopted and illustrated by the learned and ingenious Father Buffier. It is supposed to explain, why, in Africa, a black complexion, woolly hair, a flat nose, and thick lips, are esteemed beauties, while their opposites only are admired in Europe: And it professes to determine what is justly considered as a desideratum, the *standard of beauty*; which, according to this theory, is that which is most common to all the individuals of a species; and of which, though the whole parts may not be found in any one individual, yet something may be contributed by them all. Specious, however, as this theory seems to be, it will by no means apply in a multiplicity of instances; for numberless beautiful objects are to be found, which deviate very widely from the common standard of their species. The most common, or standard forms, of any species, are those which are viewed, perhaps, with the greatest indifference, being possessed of no other quality than mediocrity, which is as remote from beauty, on the one hand, as it is from deformity on the other.

"So far is perfection, considered as such, from being the cause of beauty," remarks Mr Burke, "that this quality, where it is highest in the female sex, almost always carries with it an idea of weakness and imperfection. Women are very sensible of this; for which reason they learn to lisp, to totter in their walk, to counterfeit weakness, and even sickness. In all this they are guided by nature. Beauty in distress is much the most affecting beauty. Blushing has little less power; and modesty in general, which is a tacit allowance of imperfection, is itself considered as an amiable quality, and certainly heightens every other that is so. I know it is in every body's mouth, that we ought to love perfection. This is to me a sufficient proof, that it is not the proper object of love. Who ever said, we ought to love a fine woman, or even any of those beautiful animals which please us? Here to be affected there is no need of the concurrence of our will." Part iii. sect. 10.

The celebrated Dr Hutcheson, of Glasgow, proposed a theory of beauty, which was greatly admired in its time, and likewise, for a while, very generally adopted. According to this theory, beauty consists in a certain determinate combination of variety of parts, with uniformity of structure. This system, which is sustained by all the formality of mathematical demonstration, lays it down, that of two given bodies, if the number of parts

be the same, the beauty will be as the uniformity of structure; if the uniformity be the same, the beauty will be as the variety of parts; if neither be the same, the beauty will be in the compound ratio of the variety and uniformity. Thus, an equilateral triangle is more beautiful than one with unequal sides, because, with the same number of parts, it possesses more uniformity of structure. A square is more beautiful than an equilateral triangle, because with the same uniformity of structure, it possesses a greater variety of parts. An ellipsis nearly equals the beauty of a circle, because, with less uniformity of structure, it has greater variety of parts; and so forth.

"The beauty of an equilateral triangle," says Dr Hutcheson, "is less than that of a square, which is less than that of a pentagon, and this again is surpassed by the hexagon. When, indeed, the number of the sides is much increased, the proportion of them to the radius, or diameter of the figure, is so much lost to our observation, that the beauty does not always increase with the number of sides; and the want of parallelism, in the sides of heptagons, and other figures of odd numbers, may also diminish their beauty. So in solids, the eicosiedron surpasses the octaedron, which is still more beautiful than the cube, and this again surpasses the regular pyramid; the obvious ground of this is greater *variety* with equal *uniformity*."—Instances of the compound ratio we have, in comparing circles or spheres with ellipses or spheroids, not very eccentric; and in comparing the compound solids, the exoctaedron, and eicosidodecaedron, with the perfectly regular ones of which they are compounded; and we shall find, that the want of that most perfect *uniformity* observable in the latter, is compensated by the greater *variety* in the others, so that the *beauty* is nearly equal." *Inquiry concerning Beauty, Order, &c.* p. 16.

This theory may have some plausibility when applied to works of art; but it is altogether defective when applied to the beauties of nature. Dr Hutcheson, indeed, illustrates his doctrine by examples, deduced not only from artificial figures, but from the outward form and inward structure of animals; from the proportion of their parts to each other; from the harmony of sound; from general theorems, &c. But there may be a great deal of beauty where there is no variety at all, as in a single agreeable colour, or a single melodious sound; and many beautiful objects have a variety amounting to intricacy. In the beauties of nature, we must take into the account simplicity, elegance, delicacy, and a number of qualities which are totally disregarded in the theory of Dr Hutcheson.

The ingenious Mr Hogarth, in his *Analysis of Beauty*, seems to consider *variety* as its most essential characteristic: he enumerates, indeed, five other qualities, as contributing to our approbation of beautiful objects, namely, fitness, uniformity, simplicity, intricacy, and quantity; but rather as secondary and subsidiary causes of this approbation, than as the primary and essential requisites of beauty. He expressly lays it down, that "those lines which have most variety in themselves contribute most towards the production of beauty;" and that the most beautiful line by which a surface can be bounded, is the waving, or serpentine, or that which continually and imperceptibly deviates from the straight line. This, which is so frequently exhibited in shells, flowers, and other pleasing productions of nature, he calls the *line of beauty*; and another line, which he calls

the *line of grace*, is the same waving curve twisted spirally round a solid body, as in the worm of a common jack, or the horns of various animals. On the curling worm-wheel of the jack, Mr Hogarth descants with peculiar delight. It is, he says, always pleasing, either at rest or in motion; but particularly attractive when in motion. "I never can forget," he adds, "my frequent strong attention to it when I was very young; and that its beguiling movement gave me the same kind of sensation then, which I since have felt at seeing a country dance, though perhaps the latter might be somewhat more engaging, particularly when my eye eagerly pursued a favourite dancer, through all the windings of the figure." *Analysis of Beauty*, ch. v.

Mr Hogarth's theory, like that of Dr Hutcheson, undoubtedly takes too limited a view of the sources of the beautiful. Many other qualities, besides gradual variation of outline, have a share in producing this effect, while many beautiful forms may be pointed out, in which the straight line entirely predominates. This we shall immediately have occasion to illustrate more particularly; and in the mean time shall be content with observing, that the Grecian nose, which is perfectly straight, has as many admirers as the Roman, with all the advantages of its graceful curvature.

Various authors, as if despairing of being able to resolve beauty into its absolute essence, have contented themselves with an enumeration of the various qualities which most eminently distinguish beautiful objects; and which may therefore be said to form the constituents of beauty. In an ingenious performance called *Crito, or a Dialogue on Beauty*, ascribed to the author of *Polymetis*, the constituent qualities of beauty, at least in the female sex, are reduced to four; viz. colour, form, expression, and grace; the two former of which may be called the body, and the two latter the soul of beauty. Mr Burke is inclined to consider beauty as a quality in bodies acting mechanically upon the human mind, through the medium of the senses, and arising from the following particulars: smallness of size, smoothness, gradual variation of outline, delicacy, and colour. This, at best, can be looked upon only as an enumeration of beautiful qualities, and not an analysis of beauty itself. But even contemplated as a mere enumeration, this account of the matter is very unsatisfactory; for we have just seen that gradual variation of outline is by no means essential to beauty; and so far is smallness of size from being so, that Mr Hogarth, as above mentioned, considers quantity, or greatness of dimension, as an important constituent of beautiful objects.

The insufficiency of all those systems that attempt to reduce beauty to certain permanent and invariable qualities in objects, has been very satisfactorily proved by Mr Alison, in his *Essays on the Nature and Principles of Taste*, in consequence of a very careful and judicious examination of the distinguishing properties of all those objects that we denominate beautiful. "It should seem," says this ingenious author, "that a very simple and a very obvious principle is sufficient to guide our investigation into the source of the beauty of the qualities of matter. If these qualities are in themselves fitted to produce the emotion of beauty, (or, in other words, are in themselves beautiful,) I think it is obvious that they must produce this emotion, independently of any association. If, on the contrary, it is found, that these qualities only produce such emotion when they are associated with interesting or affecting qualities; and that

when such associations are destroyed, they no longer produce the same emotion, I think it must also be allowed, that their beauty is to be ascribed, not to the material, but to the associated qualities." (*Essay 2.*) Having laid down this general principle, Mr Alison proceeds to examine whatever is considered as beautiful in the material world, contemplated under the various aspects of sounds, colours, forms, and motions; and infers, that it is principally, or solely in consequence of association, that we ascribe beauty to many of these, and not in consequence of any permanent material qualities; because he finds nothing in the qualities themselves when simply considered, calculated to raise any emotion in the mind; because it is only with persons who have such associations that these qualities are considered as beautiful, and because, when these associations are destroyed, the beauty of the qualities is destroyed at the same time.

A few examples will render this doctrine intelligible to our readers; and first in the case of sounds. With respect to musical sounds, the most extensively pleasing of this class, Mr Alison is of opinion, that there are two distinct species of pleasure of which they are productive. 1. That mechanical pleasure, which, by the constitution of our nature, accompanies the perception of a regular succession of related sounds. 2. That pleasure which such compositions of sound may produce, either by the expression of some pathetic or interesting affection, or by being the sign of some pleasing or valuable quality, either in the composition or the performance. That musical sounds are calculated to please in consequence of the original constitution of our nature, is plainly evinced by this, that their proportions and relations to one another admit of being accurately ascertained, and even mathematically demonstrated. A melodious tone is naturally pleasing in itself, and a regular succession of such tones, in a certain proportion to each other, both in respect of their duration and of their musical pitch, is naturally pleasing to all classes of mankind. In so far, therefore, music is beautiful in itself; but even in the case of music, no small share of our gratification is to be ascribed to its expression, or to the feelings which are associated with the particular composition. To the time of music, as quick or slow, we associate the ideas of cheerfulness or melancholy; and to any succession of notes intended to be imitative of certain sounds in nature, we associate the expression connected with those sounds. All music which is passionate, or indicative of any emotion, can be so only in consequence of the effect of association; and vocal music, which is avowedly the most powerful in its effects, brings to its assistance all the charms and pathos of poetry. Were the effects of music purely mechanical, and unaided by occasional association, a piece of music ought to produce precisely the same effect upon all descriptions of people, and upon all occasions, which is confessedly contrary to experience.

But again, in the scenes of nature, there are many sounds which are productive of the emotion arising from beauty, in consequence alone of the pleasing associations with which they are connected; such as the sound of the waterfall, the murmuring of the rivulet, the whispering of the wind, the sheep-fold bell, the toll of the curlew, &c. And that these sounds are beautiful only in consequence of the emotions which are associated with them, may be inferred from the insignificance of the sounds themselves; from their being perfectly

indifferent to the vulgar, who have no such associations, and even to ourselves, unless when they suit the general character of the scene, or the particular train of mind in which we may happen to be. The same remarks are applicable to the notes of animals, commonly allowed to be beautiful; although, in the case of singing birds, allowance must be made for the musical melody which nature has bestowed upon that class of her creatures. The bleating of the lamb, the lowing of the cow, the call of the goat, the hum of the beetle, or the twitter of the swallow, will all occasionally be listened to with delight, but surely not in consequence of any inherent beauty which they possess. "A peasant would laugh," says Mr Alison, "if he were asked, if the call of a goat, or the bleating of a sheep, or the lowing of a cow, were beautiful; yet in certain situations, all of these are undoubtedly so. A child shews no symptom of admiration at those sounds which are most affecting in natural scenery to other people. Every one will recollect, in what total indifference his early years were passed, to that multitude of beautiful sounds which occur in the country; and I believe, if we attend to it sufficiently, it will be found, that the period when we became sensible to their beauty, was, when we first began to feel them as expressive, either from our own observation of nature, or from the perusal of books of poetry. In the same manner, they who travel into very distant countries, are at first insensible to the beauty which the natives of these countries ascribe to the notes of the animals belonging to them, obviously from their not having yet acquired the associations which are the foundation of their beauty. The notes which are sacred from any kind of superstition, are beautiful only to those who are under the dominion of that superstition. A foreigner does not distinguish any beauty in the note of a stork. To the Hollander, however, to whom that bird is the object of a very popular and very pleasing superstition, this note is singularly beautiful." *Essay ii. ch. ii. Sect. 1. p. 1.*

Colour has always been admitted as a copious source of beauty, and no doubt part of its effect is to be ascribed to the mechanical constitution of the human body, in consequence of which, certain colours naturally excite a pleasing sensation, while others are disagreeable, and even painful. Thus green, blue, and the middle tints of the rainbow, are refreshing and agreeable to the sight, and on that account are always esteemed beautiful. But by far the greatest effect of colour, considered as an object of beauty, is shewn by Mr Alison to arise from the imagery with which it is associated in our minds; and the pleasing and affecting qualities of which it is expressive. The associations with which colours are connected, are reduced by this author under the three following heads: 1. Such as arise from the nature of the objects thus permanently coloured. 2dly, Such as arise from some analogy between certain colours, and certain dispositions of mind; and, 3dly, Such as arise from accidental connections, whether national or particular.

The following are examples of the first kind of association: White, as it is the colour of day, is expressive to us of the cheerfulness or gaiety which the return of day brings. Black, as the colour of darkness, is expressive of gloom and melancholy. The colour of the heavens, in serene weather, is blue: blue, therefore, is expressive to us of somewhat of the same pleasing and temperate character. Green is the colour of the

earth, in spring; it is consequently expressive to us of some of those delightful images which we associate with that season. The colours of vegetables and minerals acquire, in the same manner, a kind of character from the character of the species which they distinguish. The expression of those colours, which are the signs of particular passions in the human countenance, and which, from this connection, derive their effect, every one is acquainted with.

Again, there are many colours which derive expression from some analogy between them and certain affections of the mind; on which account, they obtain the names of soft or strong, mild or bold, gay or gloomy, cheerful or solemn, &c. And, lastly, there are many colours which acquire character merely from accidental association. Thus purple has acquired a character of dignity, from its accidental connection with the dress of kings. Black, in this country, indicates gravity; and scarlet is connected with military ideas. In other countries, the same colours are expressive of very different characters, because of different associations. Thus in China, white is gloomy, because the colour allotted to mourning; and yellow is the most dignified colour, because it is that allotted to the royal family. In Spain and Venice, on the contrary, black is a lively colour, because it is this that distinguishes the dress of the great. All this serves very plainly to shew, that the character of colour depends more upon the qualities with which it is associated, than upon any thing inherent in its own nature.

That the beauty of colour is to be ascribed to expression, farther appears from this, that those colours which, in general, we call beautiful, cease to be so when associated with mean ideas; and that the most indifferent colours become beautiful, in consequence of dignified associations. The colours which distinguish the dress of the common people are never considered as beautiful, although often the most brilliant of the rainbow; while those which are worn by the gay and the fashionable become immediately pleasing, whatever may be the disagreeable associations with which they are more directly connected. "A plain man," says Mr Alison, "would scarcely believe, that the colours of a glass bottle, of a dead leaf, of clay, &c. could ever be beautiful; yet within these few years, not only these, but some much more unpleasable colours that might be mentioned, have been fashionable and admired. As soon, however, as the fashion changes, as soon as they whose rank or accomplishments give this fictitious value to the colours they wear, think proper to desert them, so soon the beauty of the colour is at an end." (*Essay* ii. ch. ii. sect. 2.) In the same manner, the colours of common implements, or pieces of furniture are never admired; while those of mahogany, cedar, satin-wood, &c. although far from naturally pleasing, are, on account of the costliness of the materials, preferred by us to the most brilliant colours with which these valuable woods could be painted.

We come now to the beauty of forms, the most difficult branch of the subject, and that on which Mr Alison has exhibited the greatest portion of originality and ingenuity. It seems to have been implicitly assumed by all preceding inquirers into the characteristics of beauty, that some forms were essentially, and by their very nature, more beautiful than others; hence the ideal line of beauty and of grace,—the serpentine, and gradually curling outline of Mr Hogarth and his followers. Mr Alison seems completely to have proved, that forms are beau-

tiful, solely in consequence of association, and of the qualities of which they are expressive; that all forms are beautiful, which are expressive of delicacy or tenderness; that the angular form, when it has this expression, is reckoned as beautiful as the curvilinear; and that the curvilinear, when it is deprived of this expression, ceases any longer to be beautiful.

The cause of the general prejudice in favour of the winding line, as constituting the true line of beauty, is thus satisfactorily explained by Mr Alison: "The greater part of those bodies in nature, which possess hardness, strength, or durability, are distinguished by angular forms. The greater part of those bodies, on the contrary, which possess weakness, fragility, or delicacy, are distinguished by winding or curvilinear forms. In the mineral kingdom, all rocks, stones, and metals, the hardest and most durable bodies we know, assume universally angular forms. In the vegetable kingdom, all strong and durable plants are in general distinguished by similar forms. The feebler and more delicate race of vegetables, on the contrary, are mostly distinguished by winding forms. In the animal kingdom, in the same manner, strong and powerful animals are generally characterised by angular forms: feeble and delicate animals, by forms of the contrary kind. In consequence of this very general connection in nature, these different forms become expressive to us of the different qualities of strength and delicacy. In all those bodies which have a progress, or which grow and decay within our own observation, the same character of form is observable. In the vegetable kingdom, the infancy or youth of plants is in general distinguished by winding forms. The infancy and youth of animals is, in the same manner, distinguished by winding or serpentine forms. Their mature and perfect age, by forms more direct and angular. In consequence of this connection, forms of the first kind become in such cases expressive to us of infancy, and tenderness, and delicacy; and those of the second kind of maturity, and strength, and vigour. Besides these very obvious associations, it is also to be observed, that, from the sense of touch, angular forms are expressive to us of roughness, sharpness, harshness; winding forms on the contrary, of softness, smoothness, delicacy, and fineness; and this connection is so permanent, that we immediately infer the existence of these qualities when the bodies are only perceived by the eye. There is a very strong analogy between such qualities as are perceived by the sense of touch, and certain qualities of mind, as in all languages such qualities are expressed by terms drawn from the perceptions of the external sense. Such forms, therefore, when presented to the eye, not only lead us to infer those material qualities which are perceived by the sense of touch, but along with these, to infer also those qualities of mind, which, from analogy, are signified by such qualities of matter; and to feel from them some degree of that emotion which these dispositions of mind themselves are fitted to produce." *Essay* ii. ch. iv. sect. 1. part 2.

That it is only in consequence of the expression of delicacy, that the winding form is esteemed beautiful, may be inferred from this, that when this expression or association is destroyed, the form immediately loses its beauty. It is possible, by mechanical means, to bend bars of metal into waving lines; but the effect is far from pleasing, because instead of delicacy, it becomes expressive of force and constraint; and if in any case such forms exhibited in metal are pleasing, it is when

the material is brought to a very fine texture, as in the imitation of delicate shrubs; or when the workmanship is so exquisite, as to bestow on the subject a character of delicacy, which does not properly belong to it. Neither is the crooked or curvilinear form pleasing in the stems or branches of trees, or in the more robust plants; because here, instead of being expressive of ease, it rather denotes force and constraint.

But again, angular forms themselves are beautiful, when expressive of fineness, tenderness, or delicacy. "The myrtle for instance," says Mr Alison, "is generally reckoned a beautiful form, yet the growth of its stem is perpendicular, the junctions of its branches form regular and similar angles, and their direction is in straight or angular lines. The known delicacy, however, and tenderness of the vegetable, at least in this climate, prevails over the general expression of the form, and gives it the same beauty which we generally find in forms of a contrary kind. How much more beautiful is the rose tree when its buds begin to blow, than afterwards when its flowers are full, and in their greatest perfection: yet in this first situation, its form has much less winding surface, and is much more composed of strait lines and of angles, than afterwards, when the weight of the flower weighs down the feeble branches, and describes the easiest and most varied curves. The circumstance of its youth, a circumstance in all cases so affecting; the delicacy of its blossom, so well expressed by the care which Nature has taken in surrounding the opening bud with leaves, prevail so much upon our imagination, that we behold the form itself with more delight in this situation, than afterwards, when it assumes the more general form of delicacy. It is on a similar account, that the leaves of vegetables form a very common and a very beautiful decoration, though they are less distinguished by winding lines, than almost any other part of the plants. There are an infinite number of the feebler vegetables, and many of the common grasses, the forms of which are altogether distinguished by angles and straight lines, and where there is not a single curvature through the whole, yet all of which are beautiful, and of which also some are imitated in different ornamental forms with excellent effect, merely from the fineness and delicacy of their texture, which is so very striking, that they never fail, when we attend to them, to afford us that sentiment of interest and tenderness, which in general we receive from the opposite form. There are few things in the vegetable world more beautiful than the knotted and angular stem of the balsam; merely from its singular transparency, which it is impossible to look at without a strong impression of the fineness and delicacy of the vegetable. Such observations, with regard to flowers or plants, every person has it in his power to pursue. There is not, perhaps, any individual of the vegetable kingdom, which, if it is remarkable for its delicacy or tenderness, is not also considered as beautiful in its form, whether that form be winding or angular."

In many of those arts, where the beauty of form is chiefly consulted, the curvilinear form, being less expressive of delicacy than the angular, has no place. In most of the ornamental manufactures of metal, as in that of cut or polished steel, the expression of delicacy requires that the bulk of the material should be as much reduced as possible; and hence the predominance of sharp angles and plane facets. A sword hilt, or a watch chain, are infinitely finer and more beautiful, when they

are composed of angular forms, than when they are composed of curves. In the forms which are given to jewels, the same rule universally obtains; the same is true of the manufactures of glass for ornamental purposes. The delicacy of such subjects is in their brilliancy; and the form which displays that quality is the only one that is beautiful in them. In the articles of our household furniture, also, the same regard to lightness and delicacy of structure may be traced in many of the prevailing angular forms. "Strong and massy furniture," observes Mr Alison, "is every where vulgar and unpleasing; and though, in point of utility, we pardon it in general use, yet, wherever we expect elegance or beauty, we naturally look for fineness and delicacy in it. The actual progress of taste, in this article, is from strength to delicacy. The first articles of furniture, in every country, are strong and substantial. As taste improves, and as it is found that beauty, as well as utility, may be consulted in such subjects, their strength and solidity are gradually diminished, until, at last, by successive improvement, the progress terminates in that last degree of delicacy, and even of frugality, which is consistent either with the nature of the workmanship, or the preservation of the subject."

If this doctrine, concerning the beauty of form, be just, it should follow, that in those forms, which are of a very compound nature, the beauty does not arise so much from a certain mixture of variety and uniformity, as from a certain characteristic expression belonging to the whole. And this is perfectly consistent with the common language of men, who, when describing such complex objects, as a garden, or particular scene of nature, uniformly speak of them as *expressive* of greatness, wildness, gaiety, tranquillity, melancholy, or some other affecting quality. With respect to the artificial composition of complex beautiful forms, Mr Alison declares the total insufficiency of Mr Hogarth's rule, viz. "To make choice of a variety of lines, and vary their situations with each other, by all the different ways that can be conceived, and, at the same time, (if a solid figure be the subject of the composition), the contents or space that is to be enclosed within those lines, must be duly considered, and varied too as much as possible with propriety." Instead of this, Mr Alison proposes, that some characteristic or expressive form should be selected, and that the variations, whether in the form, number, or the proportion of the parts, should be adapted to the peculiar nature of this expression, or of that emotion which it is fitted to excite in the mind of the spectator. *Essay* ii. ch. iv. sect. 1. part 3.

The beauty of motion still remains to be mentioned; and, like the beauty of form, it arises principally, or solely, from expression. Slow and gentle motion, being indicative of ease and delicacy, is in general the most beautiful; such as the soft gliding of a stream, or the light traces of a summer breeze upon a field of corn. These are beautiful when in straight lines; but still more so, when they describe serpentine or winding lines; because still more indicative of ease. But though slow motion is, in general, the most beautiful, rapid motion may become so, when the bodies moved excite only pleasing or moderate affections. Thus the quick ascent of fire-works, and the rapid shooting of the auro-*boralis*, are extremely beautiful; though the rapid shooting of lightning is too terrific to possess such a character. The motion of the humming-bird, too

though more rapid than that of the eagle, is considered as beautiful, on account of the delicacy of the object moved.

It seems, then, to be clearly proved by Mr Alison, that the beauty of material objects does not result from any permanent qualities in the objects themselves, but from the *expression* of the objects, or, "from their being the signs or expressions of such qualities as are fitted by the constitution of our nature to produce *emotion*." The expression that may be said most generally to prevail in beautiful objects, particularly those that are judged of by the eye, is that of gentleness, delicacy, or tenderness, a quality extremely well-suited to excite emotion blended with affection, or that kind of love which, according to our original definition, is the characteristic effect of beauty. Along with this expression of delicacy, or gentleness, there may, however, be combined the expression of some other valuable quality, which will enhance the approbation and delight, with which we contemplate objects merely beautiful; and produce an emotion of a more complicated and pleasing kind than that which beauty alone excites. Thus beauty may exist in combination with *design*, or a skillful combination of parts, as in a poem, a painting, a musical composition, or a machine; and in consequence of this combination, our approbation will be enhanced. The *beauty of design* is a phrase or expression of frequent occurrence, and shews the connection between the emotions which belong to the perception of those several qualities. Another adventitious aid to beauty is *fitness*, or the proper adaptation of means to an end, subservient to which, and also to design, is the beauty of *proportion*." In the forms of furniture, of machines, and instruments in the different arts, the greater part of their beauty arises from the consideration of fitness; nor is there any form which does not become beautiful, in this sense, where it is found to be perfectly adapted to its end. "A ship which is well built, and which promises to sail well," says Mr Hogarth, "is called by sailors a beauty." "There is nothing more common, in books of anatomy, or natural history," says Mr Alison, "than the term beauty applied to many common, and many disagreeable parts of the animal frame; nor is there any reader, who considers the subjects in the light of their fitness alone, who does not feel the same emotion with the writers. A physician talks even of a beautiful theory of dropsies or fevers, a surgeon of a beautiful instrument for operations, an anatomist of a beautiful subject or preparation. These instances are sufficient to shew, that even the objects which are most destitute of natural beauty, become beautiful, when they are regarded only in the light of their fitness; and that the reason why they do not always appear beautiful to us, is that we in general leave this quality out of our consideration."

Lastly, beauty may be combined with *utility*, as it actually is in almost all the productions of nature; and by this combination, the delight with which we contemplate an object, is in the highest degree enhanced. On the superiority, in this respect, of the works of nature over those of mere art, there is a fine observation by Mr Hogarth. "Here, I think," says that ingenious artist, "will be the proper place to speak of a most curious difference between the living machines of nature in respect of fitness, and such poor ones in comparison with them, as men are only capable of making. A clock by the government's order has been made by Mr Harrison,

for the keeping of true time at sea, which is, perhaps, one of the most exquisite movements ever made. Happy the ingenious contriver! although the form of the whole, or of every part of this curious machine, should be ever so confused, or displeasingly shaped to the eye, and although even its movements should be disagreeable to look at, provided it answers the end proposed: an ornamental composition was no part of his scheme, otherwise than as a polish might be necessary; if ornaments are required to be added to mend its shape, care must be taken that they are no obstruction to the movement itself, and the more as they would be superfluous as to the main design. But in Nature's machines, how wonderfully do we see beauty and use go hand in hand? Had a machine for this purpose been Nature's work, the whole and every individual part might have had exquisite beauty of form, without danger of destroying the exquisiteness of its motion, even as if ornament had been the sole aim; its movement, too, might have been graceful, without one superfluous tittle added for either of these lovely purposes."

Thus have we endeavoured to ascertain the source of the quality of beauty in the various classes of objects, whether we take the term in its more appropriate, or in its more vague and indeterminate sense, that is, whether it denote a quality exciting a certain degree of affection and love, or a quality exciting only complacency and mental approbation. In both cases, we find beauty to arise, not so much from any determinate properties of matter, as from the expression of the whole, and the emotion which it is calculated to raise. Objects more strictly called beautiful, are generally expressive of delicacy or tenderness; and those which are called beautiful, from analogy, and a certain relation to their objects, are expressive of some valuable property, such as design, fitness, proportion, or utility; which may be called beautiful, even when existing alone, but much more so, when united with real beauty and grace. It remains, before finishing the subject, that we say a few words on the beautiful in human character, or on what is properly termed *intellectual and moral beauty*.

There are many qualities of the mind which are always considered as amiable, and excite affection in those who contemplate them; such are innocence, condescension, humanity, natural affection, and the whole train of the soft and gentle virtues. It is to such qualities that the epithet of the *beautiful in human character* properly belongs; and the analogy between them and the properties in material objects which are justly termed beautiful, is sufficiently apparent, as both are expressive of delicacy or tenderness. There are, on the other hand, certain virtues of the mind that raise admiration rather than affection; and are therefore sublime rather than beautiful; such as magnanimity, fortitude, self-command, superiority to pain and labour, superiority to pleasure, and to the smiles of fortune, as well as her frowns. These awful virtues constitute what is most grand in the human character; the gentle virtues, what is most beautiful and lovely. Thus the qualities of mind are a copious source both of beauty and sublimity:

"Mind, mind, alone! bear witness, earth and heaven,
The living fountains in itself contains
Of beauteous and sublime. Here, hand in hand,
Sit paramount the Graces. Here, enthroned,
Celestial Venus with divinest airs,
Invites the soul to never-fading joy,"

ARENSIDE.

"Those virtues," says Mr Burke, "which cause admiration, and are of the sublimer kind, produce terror rather than love; such as fortitude, justice, wisdom, and the like. Never was any man amiable by force of these qualities. Those which engage our hearts, which impress us with a sense of loveliness, are the softer virtues; easiness of temper, compassion, kindness, and liberality; though certainly those latter are of less immediate and momentous concern to society, and of less dignity. But it is for that reason that they are so amiable. The great virtues turn principally on dangers, punishments, and troubles, and are exercised rather in preventing the worst mischiefs, than in dispensing favours; and are therefore not lovely, though highly venerable. The subordinate turn on reliefs, gratifications, and indulgences; and are therefore more lovely, though inferior in dignity. Those persons who creep into the hearts of most people, who are chosen as the companions of their softer hours, and their reliefs from care and anxiety, are never persons of shining qualities, nor strong virtues. It is rather the soft green of the soil on which we rest our eyes when they are fatigued with beholding more glaring objects. It is worth observing how we feel ourselves affected in reading the characters of Cæsar and Cato, as they are so finely drawn and contrasted in Sallust. In one, the *ignoscendo, largiendo*; in the other, *nil largiendo*. In one, the *miseris per fugium*; in the other, *malis perniciem*. In the latter we have much to admire, much to reverence, and perhaps something to fear; we respect him, but we respect him at a distance. The former makes us familiar with him; we love him, and he leads us whither he pleases. To draw things closer to our first and most natural feelings, I will add a remark made upon reading this section by an ingenious friend. The authority of a father, so useful to our well-being, and so justly venerable upon all accounts, hinders us from having that entire love for him that we have for our mothers, where the parental authority is almost melted down into the mother's fondness and indulgence. But we generally have a great love for our grandfathers, in whom this authority is removed a degree from us, and where the weakness of age mellows it into something of a feminine partiality." *Enquiry into the Sublime and Beautiful*, Part iii. Sect. 10.

So powerful is the influence of the beauty of mind upon our affections, and so intimate the connection between that kind of beauty, and the expression which belongs to every beautiful object of the material world, that various writers, both ancient and modern, have been disposed to affirm, that *matter* derives all its beauty from the expression of certain qualities of *mind*. Such is the doctrine that appears to have been taught in the Platonic school; and which has been maintained by several writers of eminence in this country, particularly by Lord Shaftsbury, Dr Hutcheson, Dr Akenside, Dr Spence; and by Dr Reid, in his *Essays on the Intellectual Powers of Man*. Mr Alison, although the investigations which he has so successfully conducted concerning the real sources of the beautiful, all tend to establish the general principle, that beauty is resolvable into expression, is not disposed to give an unqualified assent to this theory. "If," says he, "by this doctrine it is only meant that *matter* is not beautiful in itself, without reference to *mind*; and that its beauty arises from the expressions which an intelligent mind connects with and perceives in it, I readily agree to it; and

perhaps the preceding illustrations may afford it some farther confirmation, by pointing out, more minutely than has hitherto been done, some of the principal classes of those expressions. But if it is further meant, that *matter* is beautiful only by being expressive of the proper qualities of *mind*; and that all the beauty of the *material*, as well as of the *intellectual* world, is to be found in *mind*, and its *qualities* alone, there seems some reason for hesitation before we admit this conclusion. That the only *subjects* of our knowledge are *matters* and *mind*, cannot be denied; but it does not follow, that all the *qualities* with which we are acquainted, must be the proper qualities either of body or of mind. There are a number of qualities which arise from *relation*; from the relation of different bodies or parts of bodies to each other; from the relation of body to mind; and from the relation of different qualities of mind to each other, that are as much the objects of our knowledge, and as frequently the objects of our attention, as any of the proper qualities, either of body or mind. Many qualities also of this kind are productive of emotion. Instead, therefore, of concluding that the beauty of *matter* arises from the expression of the qualities of *mind*, we shall rest in a more humble, but, as I apprehend, a more definite conclusion. That the beauty of the qualities of *matter* arises from their being the signs or expressions of such qualities as are fitted by the constitution of our nature to produce emotion."

Before bringing this article to a close, it may be proper to remark, that the leading principle to which we have been conducted by the preceding ample analysis, very nearly coincides with the conclusions of Professor Stewart, respecting the source of our approbation of the beautiful, as given to the world in his late volume of *Philosophical Essays*. It is the opinion of that philosopher, that the term *beauty* is first of all applied to whatever is naturally pleasing or delightful in *colours*, in some of which there is an essential and inherent source of gratification, in consequence of their agreeable action on our sense of sight, as we have had occasion to observe above. From this early and limited application, the epithet *beautiful* is, he thinks, gradually and metaphorically extended to indicate whatever is pleasing in external nature, either by its inherent qualities or by the powerful influence of casual association; and in the end it is applied even to the relations of *fitness*, *proportion*, or *utility*, the perception of which always implies some operation of the rational faculty.

It is evidently to the *expression* of objects, rather than to any precise and regularly recurring peculiarities in their constitution, that Mr Stewart ascribes their beauty; as, in the greatest variety of cases, it is by the influence of association alone that he explains our approbation, and accounts for the delight with which we contemplate whatever we consider as entitled to the name of beautiful. See Burke's *Philosophical Enquiry into the Origin of our Ideas of the Sublime and Beautiful*. Hogarth's *Analysis of Beauty*. Hutcheson's *Inquiry concerning Beauty*, &c. Price's *Review of the principal Questions in Morals*. Reid's *Essays on the Intellectual Powers of Man*. Sayer's *Disquisitions, Metaphysical and Literary*. Alison's *Essays on Taste*. Stewart's *Philosophical Essays*. (m)

BEAVER, in Zoology, the English name of the *CASTOR Fiber* of systematic naturalists. The generic and specific differences of the beaver tribe, and the peculiarities of structure that distinguish the *common beaver*

not from other quadrupeds, will be given under MAMMALIA; but in the present article we propose to describe the manners and habits of this singular animal; and, as far as possible, to correct the errors into which writers have fallen with respect to its economy.

Of no animal have the accounts given by naturalists and travellers been more extraordinary, or more marvellous. The beaver has been elevated, in point of intellect and foresight, to a rank scarcely, if at all, inferior to the human race. It has been described as raising works, and constructing habitations, which appear altogether impracticable by an animal whose utmost length does not exceed three feet, whose paws are seldom larger than a crown piece, and whose tail, though broad and flat, has naturally such an inclination downwards, that it can scarcely be brought on a line with the back. Yet it has been asserted that, with such small and unmanageable instruments, these animals are capable of driving stakes six feet long, and as thick as a man's leg, three feet deep into the ground; of wating these stakes into a kind of basket work with twigs; of building huts consisting of several apartments, and even several floors, the latter being supported on notches cut in the upright stakes, and of plastering the walls and ceilings of these apartments with mud, so as to form a smooth and uniform surface. Incredible as these assertions may appear, they were not unsupported by testimony; but this testimony seems to have been the result of hasty observation, assisted by that love of the marvellous, so natural to a lively traveller; and it has been flatly contradicted by later observers of equal credibility, and apparently of more experience. Still, however, though we abandon these *questionable* parts of the natural history of the beaver, enough remains abundantly to excite our interest and admiration.

Beavers are found in most of the northern regions of Europe and Asia, and were formerly not uncommon in Britain. At present, they are met with in the greatest numbers in North America, where the hunting these animals, and collecting their furs, form a very important object of commercial traffic. In their natural state, they subsist entirely on vegetable food, such as roots, young wood, and the bark of trees; and as, during summer, these are to be obtained in great abundance, the beavers pass that season in wandering, dispersed about the meadows and thickets that border the lakes and rivers which abound in North America. Here they ramble at their ease, retiring, for occasional shelter or repose, to the covert of bushes; and when any sudden noise indicates the approach of danger, of which they receive notice by proper centinels, they seek a sure retreat in the neighbouring waters.

Towards autumn they quit their roving way of life, form themselves into communities, and, instructed by that admirable instinct, of which we have so many examples in the history of the animal creation, begin to provide for the wants of a season, whose duration and inclemency would effectually preclude a regular supply of their accustomed nourishment. On the approach of winter, those beavers which constitute an established society retire to their old habitations, while such as have formed new colonies set about constructing cabins for themselves.

The winter quarters of the beavers are situated on the bank of a river or a creek, or, where these are not to be found, on the edge of a lake or pond. In selecting the exact spot where they may form their houses,

they appear to be guided by two considerations, viz. a sufficient depth of water, to prevent its being completely frozen, and the existence of a current, by means of which they can readily convey wood and bark to their habitations. To prevent the water from being drained off, when the frost has stopped the current towards its source, the beavers construct a dam across the stream; and in this work they certainly display wonderful sagacity, skill, and perseverance. The dam is constructed of drift-wood, branches of willows, birch, poplars, stones, and mud, brought by the beavers in their mouths, or between their paws, and not, as many have asserted, on their tails. These materials are not arranged in any particular order, but are placed indiscriminately in such a manner as to stem the current to the best advantage. If the current be slow, the dam runs straight across; but if the stream be rapid, the dam is formed with a regular curve, having the convexity towards the current, so as effectually to resist the force of the water and ice that rush down during the storms of winter, or the thaws that take place in spring. These dams are several feet in thickness, and of such strength, when completely formed, that a man may walk along them with perfect safety. As these dams are of the highest importance, the beavers are careful to keep them in constant repair; and if, by any accident, or the mischievous curiosity of human intruders, a part of this essential wall should give way, they immediately collect all their forces, and stop the fatal breach.

Having completed their dam, they proceed to construct their cabins. These are partly excavations in the ground, though their roofs form a sort of vaulted dome, that rises a little above the surface. They are formed of the same materials as the dams, but, according to Mr Hearne, they by no means exhibit that neatness and architectural skill, for which they have been celebrated by Buffon and other French writers. Mr Hearne assures us, that the houses have seldom more than one apartment, and never more than one floor, which is raised in the middle, to allow of the inhabitants eating and sleeping in a dry situation. The principal entrance and outlet to these houses is next the water, on the very edge of which they are constructed; and the opening always slopes towards the water, till it terminates so far below its surface, as to preserve a free communication in the most severe frosts. Some writers affirm, that this is the only opening to the house; but as the animals cannot live without free air, we must assent to those who describe another, though smaller, opening next the land. The houses are of various sizes, in proportion to the number of their inhabitants, which seldom exceeds ten or twelve, though sometimes double that number has been discovered in the same dwelling. Many of these houses stand together along the margin of the water, forming a village of from ten to thirty tenements.

During the latter end of summer, the beavers cut down their wood, and collect their roots. The former is kept in the water, whence they fetch it as occasion may require. In eating, they sit on their rump like a squirrel, with their tail doubled in between their hind legs, and holding their food between their paws. When disturbed, they utter a peculiar cry, and plunge into the water, flapping the ground and the water with their tail. This flapping of the tail, which is a very common custom with these animals, is considered by some writers as a premeditated signal to their associates.

Beavers are hunted both for their fur, which is very soft and glossy, and for that peculiar drug called *Castor*, which is not an *organ peculiar to the male*, as was once supposed, but a particular secreted matter, contained in little bags below the tail, and found in both sexes. (See *CASTOR*) Winter is the season chosen by the hunters for attacking the settlements of their prey. They either block up the openings next the water with stakes, and enlarge the other opening so far as to admit their dogs; or they drain off the water by breaking down the dam, and then, securing the holes of the cabins by means of nets, lay them open at the top, and catch the beavers as they endeavour to escape.

Many thousand beaver skins are annually brought to market; and we are told, that not fewer than fifty-four thousand have been disposed of by the Hudson's bay Company at one sale. Those skins are said to be in most esteem which have been worn for some time by the Indians, as the coarse long hair falls off by use, and there is left only the short soft down for which alone the furs are valued.

The fullest account of the manners and habits of the beaver has been given by Buffon in his *Natural History of Quadrupeds*, and Du Pratz, in his *History of Louisiana*; but for the most accurate history of this animal, we may refer our readers to captain Cartwright's *Journal of Transactions, &c. on the Coast of Labrador*, and Mr Hearne's *Journey to the Northern Ocean*. (*f*)

BECCARIA, GIOVAN BATISTA, a celebrated electrician of the preceding century, was born at Mondovi, in Italy, on the 3d of October 1716. We are told that he sprung from a creditable family, and that his brother Giuseppe Maria, and an uncle by the father's side, were both military officers. The first studies of Beccaria were prosecuted in the royal seminaries of his country, where, along with literature, he imbibed that love of retirement which so materially aids its cultivation; and scarcely had he attained the age of sixteen, when he repaired to Rome, for the purpose of adopting the religious habit. He accordingly became a monk of an order of regulars in the *Scudie Pie*, where he designed to complete his learning: but, urged by the influence of natural genius, he was diverted from the obscurities of scholastic inquiries to the more luminous paths of philosophy, in which he made rapid progress. He had scarcely terminated his own studies, when he was called upon to teach the belles lettres in the *Collegio d'Urbino*, one of the principal rank; and the talents and diligence which he displayed in his new office, amply justified the choice made by his superiors. Beccaria at this period produced some elegant compositions in Latin verse, which are disseminated in various collections. He admired poetry; and the works of Catullus, Virgil, and Dante, were the inseparable companions of his leisure hours. His admiration, however, of the more enlarged and solid field of mathematics and physics predominating over the fictions of poetry, he resolved thenceforward to devote himself to them exclusively. He found an opportunity of lecturing on these subjects, first in the Royal College of Palermo, and afterwards in the public schools of St Calasanzio in Rome, where his lectures were esteemed full of useful and curious information. Beccaria had likewise the good fortune to be employed in some public commissions, which were satisfactorily discharged by him; and, in particular, when the Augustine monks erected a great fabric which obscured a Portuguese church, he had to calculate the

number of hours in a year that the light was taken away, as compensation was to be made in money. He testified much zeal in inculcating the principles of science into youth; and although those in Rome capable of teaching were greater mathematicians, as Boscovich, Jacquier, and Le Sieur, he was perhaps better qualified for observing the operations of nature, and unfolding them to his pupils.

Beccaria's fame having reached the ears of his sovereign, he was, in 1748, appointed to fill the chair of natural philosophy in the Royal University of Turin, with which he received a considerable salary. On being requested by the grand duke of Savoy to repeat Needham's microscopical observations, he adapted a reflector to the solar microscope, which threw the object on a horizontal surface. Not long afterwards, directing his attention to correct the errors produced by pendulums from contraction and expansion by heat and cold, he succeeded in making an improvement on them. He devised a double pendulum, consisting of two rods, connected together in such a manner, that when one rod elevated or depressed the centre of oscillation, the other produced the opposite effect, so that this centre was always found in the same point. Beccaria likewise corrected an error of S. Gravesande concerning the velocity of a pendulum at the end of descent; and pointed out an oversight of Newton in the theory of falling bodies: He also invented an ingenious formula for finding the foci of lenses, and explained many other interesting problems in science.

The phenomena of electricity having attracted an extraordinary share of the public notice in general, as well as that of philosophers, did not escape Beccaria. He entered ardently into its principles and effects, which he endeavoured to explain by a wonderful variety of experiments and observations. These were long protracted, and frequently reverted to, and shew the fertility of his mind in analysis and combination. In this branch he has perhaps made deeper enquiry, advanced more rational theories, and thrown greater light on the operations of nature connected with it, than any other individual has done. In the year 1753, he published a volume called *Elettricismo Artificiale e Naturale*, which, after receiving numerous additions during several successive years, was, along with other tracts, translated into English in 1776. In that work he enters on all the different appearances of electricity in the natural state, and shews how they can be imitated by art. He conceives that the numerous atmospherical phenomena, not only of thunder and lightning, which constitute natural electricity in its most evident and terrific shape, but that hail, rain, and water-spouts, proceed from it; and that earthquakes and volcanoes have also an intimate relation with it.

Beccaria was appointed master of experimental philosophy by the duke of Chablais in 1764, about which time he published two dissertations on the double refraction of Iceland crystal, dedicated to the duke of York, who was then travelling through Italy; and he also wrote on the power of the electric spark and of lightning on the air. In 1774, he published the result of his measurement of a degree of the meridian, which he had undertaken by order of his sovereign, nearly ten years before, under the title of *Gradus Taurinensis*. This he had accomplished with uncommon fatigue and difficulty; but it unfortunately involved him in a serious controversy, where his skill and accuracy were equally questioned. Cassini, a noted astronomer, did not hesitate to ascribe the errors of the

measurement which he supposed to exist, to the inexperience and want of correctness of the author; and, as he was himself well practised in similar matters, his opinion could not fail to have weight. Beccaria doubted for a long time whether he should make any reply. At length he published seven letters in 1777, exculpating himself from the charge of inaccuracy, and demonstrating, that any defects and irregularities were to be imputed to the attraction of the neighbouring mountains. His theories of electricity were likewise attacked on other occasions; and he was much occupied in defending himself, which he was able to do successfully.

Beccaria's favourite pursuits occupied the greatest part of his attention; and he was continually making additions to what he had already established, and engaged in laying down new principles. These were contained in detached tracts, addressed to his literary contemporaries of eminence, or included in the publications of learned societies of which he was a member. The Royal Society of London had elected him one of its members; that of Bologna did the same; and he was an honorary member of the Academy of Painting and Sculpture at Turin.

Beccaria formed a correspondence with Dr Franklin, to whom he inscribed one of his works; and he even made a translation of Franklin's treatise on *The Increase of Mankind, and the Population of Countries*, from English into Italian, which yet remains in manuscript. Franklin entertained a high esteem for Beccaria, and dedicated to him a new invented instrument, consisting of a combination of musical glasses, which he called *Harmonica*.

The fatigues which Beccaria had undergone in completing the measurement of the terrestrial degree, had laid the foundation of a dangerous malady, which, in 1776, exhibited itself in alarming colours. Surgical aid afforded a temporary relief, but in each succeeding year the malady made frequent returns. In addition to its pressure, he was attacked by an intermittent fever, and at last sunk under the violence of both, towards the end of 1781.

During his life, Beccaria enjoyed distinguished reputation, not of that artificial kind which sometimes falsely raises men to notice, but founded on the merit of intrinsic learning. The variety and depth of his information proved that he possessed a capacious mind, one capable of embracing an extensive sphere, and of conquering the difficulties opposed to the acquisition of knowledge. Though addicting himself chiefly to the elucidation of the phenomena of electricity, from which his fame has chiefly been gained, the works which he has left on astronomical subjects and natural history deserve approbation. His industry was wonderful: besides no less than fifty different treatises published by himself, many manuscripts were found at his decease, written on topics, concerning which he had derived no previous eminence, but all evincing the power of his genius.

Notwithstanding the literary talents of Beccaria, it cannot be denied, that he was far from being a popular character. The rudeness and asperity of his manners excited disgust: his love of fame incurred the jealousy of others who beheld him with less partial eyes; and neither his fellow-citizens nor his own fraternity entertained affection for him. He would acknowledge no superior or equal in those sciences which he peculiarly cultivated, and, wrapt up in retirement, he knew little of the sentiments of his neighbours. Yet amidst all these

defects, he preserved a singular degree of fortitude, and hardly interrupted his philosophical investigations, while labouring under the excruciating pains of that disease which terminated his existence. (c)

BECCLES, a market town in the county of Suffolk, situated on the river Waveney. As Beccles has neither the advantage of the mail nor of turnpike roads, no trade of any importance is carried on in this place. The town consists of several streets, which converge into a spacious area, and is adorned with an elegant Gothic church, which commands a delightful view of the windings of the river Waveney. Population 2788, of whom 453 were returned as employed in trade. Number of houses 601. (j)

BECKET, THOMAS A, archbishop of Canterbury, was the son of Gilbert Becket, sheriff of London, and was born in that city A. D. 1119. Being destined for the church, he prosecuted his studies at Oxford with great assiduity and success; from thence he was removed to Paris, and then went to study the civil and canon law at Bologna. Endowed with great natural abilities, and possessing industry sufficient to bring them into exercise, he had attracted the regard of Theobald, archbishop of Canterbury, who, pleased with his great proficiency in knowledge, and his graceful appearance, received him into his confidence, and gave him early testimonies of his affection and friendship. He conferred upon him the prebends of London and Lincoln, and afterwards promoted him to the archdeaconry of Canterbury. Becket had been employed by his patron in some important negotiations at the court of Rome, which he conducted with such dexterity and success, that Theobald recommended him in the strongest terms to the protection and favour of Henry II. That monarch, already prepossessed in his favour, from his having been instrumental in procuring from the pope those prohibitory letters against the coronation of prince Eustace, which tended so much to his advancement, listened with satisfaction to the recommendation of the archbishop; and scarcely was Henry seated on the throne, than Becket was raised to the chancellorship of England, the first civil office in the kingdom. This sudden exaltation was only a prelude to farther honours. Besides a number of ecclesiastical benefices, he had several baronies, which had been escheated to the crown; he was made provost of Beverley, dean of Hastings, and constable of the Tower; and, to complete his grandeur, he was entrusted with the education of prince Henry, the heir apparent to the throne. The whole weight of public affairs had devolved upon Becket, and he executed them entirely to the satisfaction of Henry. His extraordinary merit had gained him the confidence of his sovereign, and, by his lively conversation and agreeable manners, he had insinuated himself into his affection and esteem. In all his actions he appeared to have his master's interest at heart; and during his relaxation from business, he was in general the companion of his amusements. Becket had laid aside almost entirely the habit and manners of an ecclesiastic. He lived in the most sumptuous and luxurious stile. His house was daily crowded with the chief nobility of the kingdom; and his magnificent entertainments, and pompous retinue, had never been equalled by any subject. The greatest barons were proud of his attention and friendship, and the king himself was frequently found at the table of the chancellor. He entered with spirit into all the exercises which were practised by the most accomplished cavaliers. Horsemanship and hunting were

his frequent amusements, and he even delighted in military fame. He attended the king in his wars at Toulouse with 700 knights at his own charge, and acquired considerable renown in the various actions in which he was engaged. In short, Becket was regarded as the gayest courtier of his time, the chief favourite of his prince, and the second person in the kingdom.

Henry had observed, with a jealous eye, the usurpations of the clergy, and from the commencement of his reign, had shewed a fixed determination to maintain his authority, and to repress every encroachment. The death of Theobald, archbishop of Canterbury, appeared a favourable opportunity for setting bounds to their power, by appointing to that high dignity a creature of his own, upon whose devotion he could depend, and from whom he might fear no opposition to his measures. The eyes of Henry were immediately turned upon Becket, from whom he had received many proofs of attachment; from whose gratitude he expected the most entire submission; from whose abilities he looked for assistance and support; and whose freedom from superstition pointed him out as the fittest person for governing the church in tranquillity. Becket was accordingly nominated to the vacant see, and was consecrated at Canterbury, June 6th, 1162. But the flattering prospects of Henry received their death-blow from the very hands by which he expected they were to be realised. The ambition of Becket had risen with his fortunes; his high spirit had escaped from the controul of civil authority; and from being the dependant of his sovereign, and the creature of his will, he now arrogated to himself the powers of an equal. His accession to the primacy was immediately followed by a complete change in his demeanour and conduct. The luxurious dainties of his table were excluded for the meagre diet of a recluse; bread and water with unsavoury herbs; his splendid apparel was replaced by sackcloth and vermin; and the gay exercises and sports of a cavalier, were exchanged for the conversation of monks, and the flagellations of penance. In imitation of our Saviour, he daily, on his knees, washed the feet of thirteen beggars, whom he afterwards dismissed with presents; and the vulgar were excited to reverence and admiration by the numerous charities, and the abstemious severity of the holy primate. His first step was to break off all connection with Henry, by returning into his hands the commission of chancellor; and he entered upon the functions of his sacred office, with the fixed purpose of defending its prerogatives, and of resisting every measure which appeared derogatory to his dignity, or subversive of his power. Not content, however, with acting upon the defensive, he was the first who provoked hostilities, by his arbitrary conduct, and illegal persecutions. The most scandalous irregularities prevailed among the lower order of ecclesiastics. Crimes of the deepest dye were daily committed with impunity; and even in cases of rape and murder, the offenders were screened by the archbishop from the punishment of the civil law. He would suffer no interference with the privileges of the church; and when commanded by Henry to revoke a bull of excommunication, he insolently returned for answer, that it belonged not to the king to inform him whom he should absolve, and whom he should excommunicate. Henry, perceiving the error into which he had fallen, in preferring Becket to a situation which presented such a wide field for his ambition, was nevertheless resolved to persist in his purpose, and to counteract, by every means, the

increasing influence and power of the clergy. In the *Constitutions of Clarendon*, which were drawn up for this purpose, the powers of the church are clearly defined, and by them ecclesiastics of every denomination are reduced to a due submission to the laws of their country. At a general council held at Clarendon, 25th January 1164, all the bishops, with Becket himself, set their seals to these constitutions, and promised with an oath, *legally, with good faith, and without fraud or reserve*, to observe them. But the refusal of Pope Alexander to ratify these laws, so hostile to ecclesiastical supremacy, furnished Becket with an excuse for withdrawing his assent; and he obtained a bull from his Holiness to relieve him from the obligation of his oath. An open rupture now ensued between Henry and the primate, which was prosecuted on both sides with equal rancour and obstinacy. But as this dispute, with its consequences, involves in it a considerable portion of English history, we shall refer for a particular developement of it to that article, and confine ourselves at present to the more prominent incidents in the life and character of Becket. By a most violent and arbitrary prosecution on the part of Henry, Becket was compelled to leave the kingdom. He was received on the continent as a persecuted disciple of the cross, and was treated with great respect and kindness by Louis VII. of France, and Pope Alexander III. the latter of whom appointed him a residence in the abbey of Potigny in Burgundy. From thence he fulminated excommunications against the ministers and chief confidants of Henry, and all who should adhere to the constitutions of Clarendon. He even threatened to excommunicate the king himself, and was prevented only by the interposition of Louis. After six years of irritation and animosity, an accommodation was brought about by means of Alexander and the king of France, when Becket was restored to his dignity and privileges. On his return to England, he was received with the highest veneration by the populace, who celebrated his entrance into Southwark with hymns of joy and acclamations. But this accommodation was immediately succeeded by fresh aggressions on the part of Becket. Scarcely was he reinstated in power, than he began to launch his spiritual thunders, and issued sentence of excommunication against all the prelates who had assisted in the coronation of the young king. When Henry was informed of this proceeding, he could not restrain his indignation; and in an unguarded moment, he was heard to express a wish that some one would deliver him from his troublesome adversary. Four barons, touched with the feelings of their master, departed with a determination either to compel the archbishop to submission, or to put him to death. They hastened to Canterbury, and found Becket at vespers in the church of St Benedict. They commanded him in the name of Henry, to absolve the excommunicated prelates, which they accompanied with reproaches and threats. But he courageously refusing to listen to their remonstrances, and haughtily defying their vengeance, they cleft his skull as he knelt at the altar, and scooping out his brains with the points of their swords, they scattered them over the pavement of the church. Thus fell Thomas a Becket, the most undaunted champion of papal supremacy, on the 29th December 1170, in the 52d year of his age.

What were the principles upon which Becket acted, whether from a love of power, or from a conscientious regard to the duties of his office, it is difficult to determine. That hypocrisy entered into his character, the

sudden change in his conduct leaves us little room to doubt; but to what period of his life it ought to be attached, whether before or after his accession to the primacy, may be disputed. In that age of superstition, every ecclesiastic was brought up with the highest ideas of the supremacy of the church; and we cannot suppose that Becket, who had been a disciple of archbishop Theobald, and who had spent a part of his life at the court of Rome, would be wanting in zeal for its interests. From the high labour in which he stood both with Theobald and his sovereign, he could not but look with confidence to the see of Canterbury; and his appearing to take little interest in ecclesiastical affairs, and to acquiesce in all those measures which Henry meditated for abridging the powers of the clergy, was, in all probability, the mask which he assumed for securing the object of his ambition; for if we may believe his biographers, though he entered into all the gallantries of a luxurious court, he remained constantly temperate and invincibly chaste. Immediately upon his exaltation, however, the mask was thrown aside, and it was then that he appeared in his real character, as the champion of the church and the defender of its rights. How far he acted in conformity with the dictates of popery; whether his errors were of judgment or of will; and what degree of moral turpitude ought to be affixed to his conduct, we leave our readers to determine. His predecessor had set him the example of opposition to his sovereign, and there were many in that age, who, had they possessed the abilities, the courage, or the persevering inflexibility of a Becket, would have acted the same part. We mean not, however, by what we have said, either to justify his measures, or the manner in which they were pursued (though the unwarrantable prosecutions of Henry might palliate in some degree his inveterate obstinacy.) But "in passing judgment upon the characters of men," says our elegant historian Robertson, "we ought to try them by the principles and maxims of their own age, not by those of another." When we reprobate Becket, then, our censure must extend to the church of which he was a member, and to the prejudices of his times, which ranked him with the most illustrious martyrs, and cherished his memory with the most superstitious veneration. Becket possessed abilities which entitled him to the high station which he attained, and which claim our admiration and respect: but his ingratitude to his master, his ambition, and his overbearing arrogance, expose him to our severest reprehension; and we cannot but lament the prostitution of those talents in the cause of a bigotted superstition, which, had they been directed to the support of law and justice, would have proved a blessing, instead of a fire-brand to his country. See Hume's *Hist. of England*, vol. i. p. 410—448. 8vo.; Lyttelton's *Hist. of Henry II.* vol. ii. p. 231, &c. 8vo.; Henry's *Hist. of Great Britain*, vol. v. p. 340, &c. 8vo. (f)

BED, a place raised above the level of the floor of an apartment, on which the body is stretched out for rest and sleep.

In ancient times the beds consisted of a heap of herbs and leaves, with the skins of beasts for a covering; and even in the time of Pliny, the soldiers when encamped made use of that rude couch. In process of time, however, the Romans constructed their beds in a more luxurious manner. The fine wool of Miletus, ebony,

cedar, and citron wood, were all employed in the construction of this piece of furniture. Sometimes they were even made of ivory and massive silver, having their coverings of purple enriched with gold.

Beds, at first employed for the purpose of recruiting the body by rest and sleep, were afterwards used for other purposes. The luxurious Asiatics stretched themselves upon beds when they devoured their meats, and the Greeks afterwards imitated this indolent practice. The ancients made use of beds when they were engaged in their prayers, and in this singular custom they were imitated by the first Christians. The ancient poets too, often recited their compositions from their beds, and even their philosophers placed themselves in that attitude of repose, when they gave lessons to their disciples. See Homer's *Iliad*, lib. xxiv. v. 644. *Pliny*, lib. viii. cap. 48; lib. xvi. cap. 36; lib. xxiii. cap. 11. *Stat.* 11 Hen. VII. cap. 19. Suetonius, *In Vit. Aug.* cum Not Casaubon. Scheffer de *Torquibus*.

An account of beds of particular constructions will be found in the *Machines Approuvées*, tom. iii. p. 67. *Phil. Trans.* 1732, p. 256. *Mem. Acad. Par.* 1742. Hist. p. 155. *Id.* 1745. BEDA, or BEDE, usually called the Venerable Bede, was born at Weremouth, in Northumberland, in the year 672; and, at the age of seven years, was sent to the monastery of St Peter, whose abbot and founder, Benedict Biscop, was one of the most learned men and greatest travellers of that age. Here he enjoyed the use of an excellent library, and the assistance of the ablest instructors. Abbot Benedict himself, Ceolfrid his successor, and St John of Beverley, were all his preceptors; by the last of whom he was ordained deacon, at 19 years of age, and priest at 30. He seems, however, to have removed to another monastery, founded also by Benedict, at Tarrow, near the mouth of the river Tyne, where he spent the remainder of his life in devout exercises and literary pursuits. By his astonishing application and comprehensive talents, he made himself master of every branch of literature, which it was possible to acquire in the period in which he lived, and in the circumstances in which he was placed. He was held in high estimation by the most eminent prelates of that age, and particularly by Egbert, bishop of York, a man of the most extensive learning. His fame was so great, that it rapidly spread through every country in Europe; and he was even invited by Pope Sergius to Rome, that he might be consulted by that Pontiff upon many subjects of importance. Bede, however, still continued his monastic course of life, diligently employing himself in the acquisition and communication of useful knowledge. He composed an astonishing number of treatises, many of which have never been

* BEDS, for the sick, of a particular form, and suspended on a portable stand, have been introduced into hospitals, &c. A description of an improved one for hospitals, &c. may be seen in the "Observations on the means of preserving the health of soldiers and sailors, &c." by E. Cutbush, M. D. Surgeon of the Navy of the United States. CUTBUSH.

published; and wrote upon so great a variety of subjects, that his works, it has been affirmed, contain all the knowledge which was then to be found in the world, and every point of antiquity, at least, which is now worthy to be read. The greatest of his writings, was the ecclesiastical history of England, which he completed in the 59th year of his age, and which is still a performance of the highest authority. His writings were so much esteemed, that even during his own life, a council held in England, and afterwards approved by the catholic church, appointed his homilies to be publicly read in the churches. He was the first who translated some parts of the Bible, especially the gospel of John, into the language of this country, which was then Saxon; and it was the anxious occupation of his last moments to finish that portion of the sacred book. All his other works were composed in the Latin language, in a style remarkable for its perspicuity and ease, but frequently deficient in purity and elegance. He could not be exempt from the influence of that credulity, which was the character of the age in which he lived; but if allowances be made for the peculiarities of his times, and the disadvantages with which he had to struggle, he must be acknowledged to have been the most laborious and ingenious person that this country ever produced. He is justly celebrated for his exemplary piety, astonishing learning, incredible application, and extreme humility. He is called by Camden, "the singular light of our island, whom we may more easily admire than sufficiently praise." He was named by his contemporaries *the Wise Saxon*; and has been entitled by posterity, *the Venerable Bede*: and indeed, "as long," says an eminent historian, "as great modesty, piety, and learning, united in one character, are the objects of veneration, the memory of Bede must be revered." He laboured, during the concluding period of his life, under a very infirm state of health, which had been induced by his unremitting application, and which he bore with devout resignation. Having exhausted his last remains of strength in dictating a translation from sacred scripture, he breathed a pious exclamation, and expired in his cell at Tarrow, in the year 735. His body was interred in his own monastery, where he died, but was afterwards removed to Durham, and placed in the same coffin with that of St Cuthbert. The first edition of his works was published at Paris, in 1544, in three volumes folio; and the latest at Cambridge in 1722, with notes and dissertations by Dr Smith, prebendary of Durham. An account of his printed pieces may be found in the notes to his life, in the *Biographia Britannica*, or in the Appendix to the 4th volume of Dr Henry's *History of Britain*; but a complete list of all his writings, drawn up by his own hand, is inserted in Muratori *Antiq. Italic. Mediæ Ævi*, tom. iii. p. 325. See *Biog. Britan. General Biog. Dict.* Henry's *Hist. of Britain*, vol. iv. Cave's *Hist. Liter.* vol. i. Warton's *Hist. of Poetry*, vol. i. p. 104.; and Mosheim's *Church Hist.* vol. ii. p. 247, 251. (g)

BEDFORD, a very ancient town in the central part of England, and the capital and only borough town in the county of the same name, (See **BEDFORDSHIRE**.) is situated on both sides, but principally on the north side of the Ouse river, which is navigable from the Eastern Sea, or German Ocean, by way of Lynn, Downham, Ely, St Ives, Huntingdon, and St Neots, to this town. Bedford is situated rather north of the centre of the county, and at the northern skirt of a very wide vale, of strong

but good clay land, called the vale of Bedford: in the immediate site of the town, several strata of grey compact limestone, abounding with gryphites and other species of fossil shells, usually denominated anomia, having very dark blue or black beds of clay between them; appear from under the thick strata of clay which compose the vale of Bedford, and the hills north of it. This limestone, which is dug and burnt on the west side of the town, and of which the churches, the bridge, and most of the ancient buildings are constructed, has hence been denominated the "Bedford limestone," in the enumerations of the British strata by Mr William Smith and his pupils. See the *Philosophical Magazine*, vol. xxxvi. p. 105.

This town was called by the Saxons, *Bedan Ford*, signifying the fortress on the ford, alluding to an immense tumulus, or mound of earth, which, perhaps prior to this, was raised by immense labour from a ditch surrounding it, on the north bank of the river, opposite to the ancient ford, and site perhaps of a bridge in more modern times, about 200 yards east of the present bridge, which is itself a work of considerable antiquity. Offa, king of the Mercians, is said to have been buried in a small chapel, seated on or near to the Ouse, in this town, of which no vestige now remains. A desperate battle was fought near this town, in 572, between Cuthwulf the Saxon king, and the Britons, which terminated disastrously to the natives; and the inhabitants of Bedford in consequence were a prey to their merciless invaders, who frequently renewed their marauding visits, until the year 911, when they were defeated and driven from this part of the country. The third baron of Bedford, Baron de Beauchamp, built a very strong and spacious castle, on and around the site of the ancient fort, surrounding the whole by a very deep ditch, vestiges of which still remain on the east and part of the north sides: the site of the castle being now occupied by the gardens and paddock belonging to the New Swan Inn; and the spacious top of the keep and tumulus above mentioned, by a pleasant bowling-green, which is surrounded by tall elm trees, that grow on the steep sides of what still bears the name of the Castle-hill.

The late duke of Bedford, justly stiled the "Great duke of Bedford," purchased the site of this castle, and a miserable inn which stood at the corner of the bridge, from one of the inhabitants, and, at the expense of 9000*l.* erected here a magnificent inn, for the general accommodation of the inhabitants and travellers, but more especially for the meetings of the justices, grand jury, &c. at the times of the assises and quarter sessions, and the inhabitants at county meetings, and on other public occasions. The south and west fronts of this building are faced with the beautiful white free-stone from the lower beds of the chalk strata, brought from Totternhoe, near Dunstable: all the other parts are of limestone, raised from the fosse of the Castle-hill just by.

The great strength of the castle of Bedford rendered it a place of contention in most of the civil wars which rent the kingdom, in the ages which succeeded its erection. King Stephen besieged this castle, and reduced it. The refractory barons, in the reign of King John, possessed themselves of Bedford castle, until expelled by Fulco de Brent, a general in the king's army, who, in reward for his services, received a grant of this castle, which he held until, in the succeeding reign, he in his turn rebelled, and was taken and sent prisoner to London, after a vigorous siege of 60 days, by Henry the

Third, who, after hanging 25 of the rebellious knights found in this castle, demolished it; since which period, the mason and the lime-burner have long removed and used every stone which formed the massive walls of this once formidable castle.

Bedford contains five different parishes, viz. St Paul, St Peter, and St Cuthbert, on the north side of the river, and St Mary and St John on its south side. St Paul's church, which was collegiate before the conquest, is the largest church, and is ornamented with a tall octagonal spire, the latitude of which, according to the government trigonometrical survey, is $52^{\circ} 8' 8''.8$ N. and its longitude $0^{\circ} 27' 43''.3$ W. of Greenwich observatory, or $1^{\circ} 50''.9$ in time. The government of the town is vested in a mayor, recorder, deputy-recorder, an indefinite number of aldermen, (who have served the office of mayor,) two bailiffs, and thirteen common councilmen. Until about the year 1798, the corporation of Bedford had for a long time numbered in its body but few of the largest merchants, traders, or opulent persons of the place, and continual jealousies and civil broils were the consequence of these distinctions, which the genius and conciliatory talents of the late duke of Bedford, their recorder, enabled them to remove, and many beneficial measures for the improvement of the town were and since have been the consequences. The bailiffs are lords of the manors, and have right of fishing in the Ouse river for nine miles each way from Bedford.

Henry III. granted the borough to the burgesses for 40*l.* yearly; but they having omitted to pay the crown rent, it was seized by Edward I. In the reign of James II., the town having neglected to return two burgesses to serve in parliament, the mayor and aldermen were expelled their offices by the king, and his ministers nominated two members of parliament for the town. Their charter was, however, restored by this king, and the right of election remains vested in the burgesses, freemen, and inhabitant householders not receiving alms, amounting to about 1400 voters.

Bedford was made a dukedom by Henry V., and the honour conferred on John Plantagenet, third son of Henry IV., who was the first duke of Bedford: a title, which was successively enjoyed by the Nevils and De Hatfields, and at length was bestowed on John Russel, the ancestor of the present duke of Bedford.

This town is distinguished as much by the variety of its religious sects, (which, besides all the common classes of religious persuasions in England, has Jews and Moravians among them,) as by the number and extent of its charitable endowments. The hospital of St John is said to have been founded in 980 by Robert de Paris, who was the first master: it now has 10 poor men under the rector of St John's church, who is the master. St Leonard's hospital was built and endowed in the reign of Edward I. and the hospital of Grey Friars in that of Edward II. by Mabilia de Paterhall. Thomas Christy founded an hospital for 8 poor people, endowed a charity-school for 40 children, and repaired the old town-hall, a wooden building, which has since been removed, to widen and open the street, and a new one erected. The benevolent and well intentioned Sir William Harper, a native of Bedford, having settled in London, and become Lord Mayor in 1561, he purchased, for 180*l.*, $13\frac{1}{2}$ acres of land in St Andrew's parish, Holborn, which, with his dwelling-house in Bedford, he bequeathed to the corporation of Bedford, for the endowment of a grammar school, and for *apportioning young women of*

the town upon marriage; a fruitful source of evil to the poor girls themselves, in the temptation to which it has exposed hundreds of them, from soldiers of marching regiments and the most abandoned individuals, who have married them in hopes of "fingering Harper's twenty pounds!" and of ruin to the town in its consequences. The original rent of this Harper charity-estate in London was 40*l.* In 1668 it was leased for 41 years, at 99*l.* per annum; and the rapid extension of London having commenced, a reversionary building lease was granted by the trustees for a further term of 51 years, at 150*l.* per annum: the whole having been covered by valuable houses, forming Bedford Row and the adjoining streets; and the leases having fallen in, and new ones been granted, the present net rent is 4000*l.*, and shortly is expected, by second renewals, to reach 5000*l.* per annum! Yet, notwithstanding all these, and numerous other sources of relief, unknown to the indigent of the greater part of the kingdom, such is the effect of charity distributed *by law*, and without sound discretion in the distributor, that Bedford, having never possessed extensive manufactures which had declined, after drawing together a surplus population, became so oppressed by poors rates, that in 1794 the inhabitants, by way of checking the growing evil, which threatened to swallow up all their property, applied to parliament for an act for consolidating the 5 parishes, as far as concerns the maintenance of the poor, and building and organising an effective "house of industry," the money for which purpose was raised principally on life annuities; a measure which, with the growing expenses of the poor, increased the poors rates to *seventeen shillings and sixpence in the pound* on the rack rents, during some years. The just terrors to the dissolute poor, of being *made to work*, if able, and a fortunate extinction of money annuities, had, however, in 1803, reduced the poors rates in Bedford to 6*s.* 4*d.* in the pound rent, (while yet, the average of the whole county, without this town, was but 3*s.* 9*d.* in the pound rent,) and a further reduction of rates has since followed; but ever must the poors rates of this town continue to mock the evils of gratuitous marriage portions, distributed with little of that sound discretion which must ever direct the distribution of *charity*, unless an evil is to be produced instead of the good intended.

The late Mr Whitbread left handsome legacies for building and endowing almshouses, and towards the erection of a county infirmary, which has since been carried into effect. A new county gaol and bride-well, and a new town gaol, have lately been built. In the loathsome gaol in this town, which has not many years been pulled down, the well-known John Bunyan wrote most of his books, in the 17th century, during a captivity of near 20 years, for the crime of *preaching*; a prosecution, instigated by a spirit of intolerance, happily unknown among the present inhabitants of Bedford. The county hall, where the sessions are held, is a handsome and commodious stone building. This town, particularly the southern part of it, is subject to inundations from the swelling of the Ouse after sudden rains: of late years these have been more frequent and greater than formerly, as is supposed from the general straightning and opening of brooks, in the many newly inclosed parishes which drain into the Ouse, which now pour their floods with more celerity than formerly, into the vale of the Ouse, whose swell, comparative declivity, and numerous mill dams and sinuosities, occa-

sions the temporary stagnation of the water, 12 or 15 feet deep on the meadows in many places, on such occasions.

Bedford is 50 miles from London, having the Leeds mail coach running through it daily: it arrives from London at 7½ hours in the morning, and leaves Bedford for London at 2½ hours in the afternoon. A bank has some years been established here, by the firm of Barnard & Co., who draw on Harrisons & Co. in London.

Thread-lace making, by the poor women and girls, is the principal manufacture of the place. Some coarse baises are made at the house of industry; a little wool-combing is done; coke is burnt, in highly domed ovens, for the use of malsters; some lime is burnt, and tiles made for sale to the neighbouring villages: besides which, we have not heard of any manufactures in this place. Bedford is, on the whole, pretty well built, and rather a handsome and clean town, with excellent gravelled roads out of it in all directions.

The town of Bedford, according to the parliamentary returns of 1801, contained 800 houses, and 3948 inhabitants: of whom 1712 were males, and 2236 females; a disproportion between the sexes, which strongly illustrates our remarks above, on premiums for marriages. There are here 2221 persons employed in trade, manufactures, and handicraft. (g)

BEDFORDSHIRE, is an inland county of England, bounded on the S. W. and W. by Buckinghamshire, on the N. W. and N. by Northamptonshire, on the N. and N. E. by Huntingdonshire, on the E. by Cambridgeshire, and on the S. E. and S. by Hertfordshire. It is situated between the parallels of 51° 47' and 52° 17' of north latitude, and between 0° 17' and 0° 46' of west longitude from Greenwich. A great part of its bounds are artificial, and strangely indented, as they are affected by the manors and properties at its edge, and not by rivers or summits of high land, which are natural divisions. The whole of this county is situated on the eastern side of the watershed or grand ridge of the island, and the whole of its surface drains to the Ouse river, with the exceptions of a tract of chalk on the south, about Luton, Sundon, Houghton-Regis, and Dunstable, which drains to the sea, and a smaller tract near Market-street, Studham, and Whipsnade, which drains to the Colne, both of these being branches of the Thames river; a small tract of clay in Dunton, Eyworth, and Wrestlingworth, which drains to the Cam; and a tract of clay and limestone land near Puddington, Farnditch, and Wimmington, at the north end of the county, which drains to the Nen.

The highest range of hills in or near to Bedfordshire is the Chiltern hills, of the upper chalk, which cross a part, and skirt the remainder of the southern extremity of this county, from Whipsnade near Dunstable, to near Baldock: and no other land in Bedfordshire approaches near to their height, as appears from the range of freestone hills across Northamptonshire from Catesby to Naseberg; and of limestone and clay from Salsey Forest near Olney, to near Higham-Ferrers, being visible by telescopes from the chalk hills across the whole of Bedfordshire. The next most considerable range in height, is of clay, crossing the county near its northern end, which it enters north-west of Harold, and proceeds by Souldrope, Bletsoe-Park, between Keysoe and Colmworth, and leaves the county near Staughton-Parva. The next most considerable range, is of sand, and enters the county near Aspley Guise, passes to Ridgemont,

near to Lidlington, Milbrook, and Ampthull; and of clay thence to Hawnes, and near to Old-Warden. Another range of alluvial clay principally proceeds from the lower chalk hills between Houghton-Regis and Sundon, and proceeds by Tuddington, Milton-Bryant, Woburn Park, and Ridgemont, (crossing here the sand ridge before described,) by Brogborough Park, Cranfield, across a neck of Buckinghamshire, and then near to Turvey, Carlton, and Pavingham. From the lower chalk hills, also near Sundon, another clay ridge branches, and passes through Harlington, and near to Silsoe and Upper Gravenhurst; and another alluvial clay range, which leaves the chalk hills east of Baldock, passes near Edworth, Dunton, Potton, and Cockayne-Hatley, into Cambridgeshire, spreading there into the wide alluvial range of clay about Caxton, and north-east of it, between the Cam and the Ouse.

The strata of Bedfordshire were examined in the year 1801, under the patronage of the "great Duke of Bedford," in the last year of his useful life, by Mr William Smith of Bath, who was at that time (and still is we believe) proposing to publish, by subscription, a map of England, shewing the range of all the principal strata across the island, and a volume explaining the same: during which examination of Bedfordshire, he was accompanied by his Grace's agent, Mr John Farey, and by his friend Mr Benjamin Bevan, who, as pupils of Mr Smith, the former in particular, have since industriously pursued the subject of stratification, and others connected with it, (See *Philosoph. Mag.* vol. xxxiii. p. 258, and vol. xxxv. p. 114.) and the making of mineral surveys, on principles which cannot fail of success, in making us acquainted with the subterranean geography of countries. From what we have learnt from Mr Farey, and other sources, we are enabled to present the following sketch of the Bedfordshire strata, as far as they are visible or accessible, owing to the vast mass of alluvial matter, (principally the broken and slightly worn ruins of the chalk and its covering strata,) of districts to the south-east of the county. See *Phil. Mag.* vol. xxxv. p. 135.

The alluvia of Bedfordshire cover at least four-fifths of its whole surface, and principally consist of yellow and dark-coloured clays (apparently the ruins of the great clay above the chalks on which London is situated,) intermixed with flint nodules, and chert nodules, in all the various degrees of breaking and rounding, also of rounding grit-stones, and of small bolders of the harder beds of chalk, and chrySTALLISED quartz pebbles, in a highly rounded state; large ludus helmanti, (such as the Roman or Parker's cement is made from in Essex, Kent, &c.) and other ferruginous nodules; rounded fragments of hard grey and blue limestones of various kinds, and with numerous shells of different sizes and species imbedded in them; rhombic crystals of selenite, cickini and their spines in flint and hard chalk, and the numerous other fossils of the chalk strata. Several of the ranges of alluvial clay hills in the above account, seem to owe the greater part of their elevation to these heterogeneous clayey mixtures, which in some instances exceed 50, 100, or even 200 feet in thickness, before the regular or undisturbed strata on which they rest can be reached. A very large portion of the space, which is coloured blue, in Thomas Batchelor's map of soils, affixed to his agricultural survey of this county, is occupied by these alluvial clays, in which, as the pebbles of quartz, chert, flint, chalk, limestone, grit-

stone, &c. and sand, more or less abound, clays and loams of almost all degrees of tenacity and fertility are produced; they are, however, generally too wet, and are difficult and very expensive to drain, owing to the uncertain and irregular mixture of the sand and gravelly patches, in and upon the tenacious clay, of which the mass principally consists. Besides these clayey and alluvial mixtures, there are in Bedfordshire great quantities of broken flints and cherts (chippings or rubble, rather than rounded gravel) intermixed with highly rounded quartz and hard chalk, and with sand, which form clear, sharp, or sandy gravels, gravelly and sandy loams, &c. most of which are very productive to the husbandman. The bottom of the vale of the Ouse, and the low hills situated in it, all the way from St Neots to Sharnbrook, and also of the vale of the Ivel from Blunham to Shefford and Arlsey, are thus covered, perhaps two miles wide on the average, with sandy gravel, which also, in lesser quantities, lines the bottoms of the vales in most or all of the sandy district, extending across the county from Leighton-Busard to Potton, and in many other parts, as well as in isolated patches, often on the tops of the clay-hills above described, and sometimes on their sides or slopes.

A more modern alluvium covers all the flat and lowest parts of the large vales, within the reach of the rivers and brooks when swollen by floods, and which is still accumulating by slow degrees from the sediment of the flood waters which overflow these flats, or tracts of meadow soil, as the hazle loam peculiar to these situations is often called. Upon the gravel, in the bottoms of the vales in the sand district, peat has grown, and, in most instances, where draining has not been effected, is still increasing, aided by the ferruginous or ochreous sediment of the floods which cover them occasionally: but whence the sulphuric acid is derived, which abounds in such quantities in the sandy peat valleys of Bedfordshire, is, as Mr Batchelor observes, page 54 of his Report before quoted, not easy to guess. As the peat of these valleys, (which has little interruption on the Ivel from Evanholt down to Sandy,) by decomposition, becomes solid and almost impervious to water, at its lower parts in particular, the springs, or soakage of the water, are collected, and make their way down the open floor of gravel, beneath the peat; and hence it happens, owing to the fall of the valley, and the superabundance of the supply from particular strata on which this gravel floor rests, that the gravel becomes charged with a column of water, which the decomposed and solid peat prevents from rising direct into the brook and escaping, and the same, therefore, makes its way up the gravel floor to the edge of the peat, where it is principally discharged to the surface of the peat; a circumstance which has contributed to its faster accumulation at the edges, and in many instances caused it to be higher by several feet along one or each side of the valley, than along the centre or brook-course. Appearances like these, of peat but moderately wet along the middle and lower line of a boggy vale, yet with water oozing through every pore of its sides, and even flowing over its higher edge, naturally enough suggested to the late Mr Elkington, when employed at Crawley bog, on the Woburn brook, and at Prisleys bog, on the Ivel, that the source of water which occasioned the bog, was from the adjoining hills; and accordingly, he set out great lengths of drains along the skirts of Crawley bog, which were executed by his own foreman, who had worked

for some years in draining under Mr Elkington in different counties. In undertaking soon after to drain the bog at Prisleys, under the inspection of a committee of the Board of Agriculture, whose certificate of success was to be Mr Elkington's title to a remuneration from parliament, for his supposed discoveries of the sources of springs, and their infallible cure by draining, Mr Elkington unfortunately made here again the mistake which has been hinted at above, and in presence of the committee, staked out a line on the south-east of Prisleys farm-house for the open drain, which was to do the business, and prescribed the exact width at top and at bottom, and its depth in various parts; which particulars being committed to writing on the spot, the duke of Bedford, at whose expense the whole experiment was made, in the presence of Mr Elkington and the committee, handed then written directions to his agent Mr Farey, who was present, and directed him to hire and superintend the cutting of the drain which he had seen staked out, in all respects conformable to Mr Elkington's written directions; and this was accordingly done, with the most scrupulous exactness, in the course of some weeks which followed. In the progress of cutting this drain, Mr Farey discovered, that the deep open cut which was making, being for the most part in alluvial clay, or in gravel with almost no water, collected little of course, although the water was oozing out of every pore of the bog within a few feet of its lower edge. These circumstances, induced him to examine this and other neighbouring valley bogs with attention, and led to the discovery of their true nature, as above; and it may be material in confirmation thereof to observe, that after the total failure of Mr Elkington's first drain at Prisleys, above mentioned, and of the numerous extensions and branches cut from it by Mr Elkington's foreman, and under his own uncontrolled directions, that these principles being explained to his Grace by Mr Farey, he obtained directions to apply them in the drainage of Crawley bog, which he soon and completely effected, merely by one open drain, up the lowest parts of the valley and bog, and the deepest of the peat, which however was cut through, and the gravel reached, in most parts of the drain. The effect of this was, that the gravel floor of the peat, with the same facility conveyed such springs as really issued out of the strata at the edges of the peat, down to the central drain, as it had before given passage to the pent column of water in the open gravel there, to flow up, and over the edges of the peat, as has been explained above. In the Grange Meadows and Pigs-Park bogs, above Crawley, the same principles were followed with similar success; and shortly after, Mr Farey effected a still larger drainage by the like simple means, under the commissioners for the inclosure of Muldun, and at the general expense of the proprietors; the works recommended by Mr Farey being such only as the commissioners judged necessary to be performed, at the public drains and brooks of the parish under the usual clauses for their improvement at the time of an inclosure, (See the *Report on Bedfordshire* above quoted, page 469). We hope to be excused for entering into the above details, on account of the importance of elucidating this case of *valley bogs*, which has not, to our knowledge, been done in any of the numerous works, which, from the date of Dr Anderson's Essays, to the present time, have been written on the principles and practice of draining.

The tops of the upper chalk hills, about Whipsnade

and Luton, have in general a covering of alluvial red clay mixed with broken flints, sometimes in such regular layers in the clay, as to have been called strata of flint, and often in such quantities, as after rain to cause the ploughed fields to appear like gravel heaps. On others of the hills of this district, particularly near Kingsworth, great quantities of the small black chert pebbles of the London clay are found, (See *Phil. Mag.* vol. xxxv. p. 131.) with broken flints and larger chert pebbles in the vallies.

The strata of Bedfordshire have an easy and pretty regular dip towards the south-east, at the rates of 1 in 50 to 1 in 80 perhaps. The uppermost stratum which appears in Bedfordshire, is a thick bed of chalk, with numerous layers of flints throughout its whole thickness; but near the top they are closer together, and the nodules larger, and the intervening chalk in this situation is more free or soft, and is alone fit for the chalking of lands and the making of whitening, on account of its friability: it is also the purest carbonate, and contains less silex and other heterogenous mixtures, than the lower chalks do. This upper chalk advances no farther northward or north-west than the hills on each side of Luton, and those south-east, south-west, and west, of Dunstable.

The hard or lower chalk next succeeds, in which no flints are found; but the chalk increases in hardness, and the quantity of the fine grains of silex which it contains, as we proceed downwards, until near its bottom, a stratum little different in appearance from those above it is found, which proves to be a very durable freestone, when seasoned or dried gradually without suffering frost to reach it, which, when fresh dug, would otherwise shiver it completely to pieces. At Totternhoe, north-west of Dunstable, there are immense and ancient workings after this stone, which will stand fire, as well as weather, in a vertical wall. Woburn-Abbey, the New Swan Inn at Bedford, and many other good buildings, are faced with this stone; and the window-jambes and ornaments of most of the churches in the midland counties are made of it. The hard beds of chalk above this Totternhoe stone, such as are seen in the second new road now cutting at Chalk, or Puddle-hill, near Dunstable, are called *hurlock*, and make a very good lime for building, probably on account of the great quantity of silex it contains; and it is from these hurlock beds, all the way from near Eaton-Bray to Baldock, that the parts north of this for several miles are furnished with lime, except a little for plasterers work or white-washing, which is brought from the softer and whiter beds of the upper chalk, to the south of the range made by the hard chalk and hurlock. The large quantity of silex, which some of this hurlock contains, may be one reason, joined with the dearness of fuel to burn it, that lime has been so little used or even tried of late years, on the clays or sands north of the chalk hills in Bedfordshire, under the idea of its not repaying the expense. The upper and lower chalk are, it is said, together about 400 feet thick.

The chalk marl is the stratum which succeeds the chalk, and on the surface when wet, makes very tenacious white or grey clayey soil; but when dry, the white colour is seldom preserved, yet a dark-coloured loam results from its decomposition, although when fresh dug into, the strata might almost be mistaken for rubble or broken hurlock. The basset, or north-western edge of this stratum, was lately exposed by the widening the

London road through Kates-hill, at the south end of Hockliff town.

In proceeding from this northward, along the road towards Towcester, nothing but thick masses of alluvial clay are seen, until near Sand-house at $40\frac{1}{2}$ miles from London; and in the other road through Woburn, the same alluvial covering prevents any observations being made on the strata, until within a quarter of a mile of Woburn town the same sand makes its appearance, from under the alluvium: and it is not a little remarkable, that the distribution of this alluvial clay is so complete across the country, all the way from Billington to Cockayne-Hatley, as shewn by the blue colour in Mr Batchelor's map above referred to, as entirely to conceal from the knowledge and use of the inhabitants of Bedfordshire, the remarkable limestone strata of Aylesbury, and several others, which no where burst through or shew themselves from under the alluvia, the "golt" of the Rev. Mr Michell. See the *Phil. Mag.* vol. xxxvi. page 103.

The Woburn sand is a name for a series of ferruginous sand strata, about 170 or 180 feet thick, whose basset crosses Bedfordshire from Leighton-Busard to Potten, as already mentioned, when speaking of the alluvium and peat upon it. In most parts this sand near the surface is cemented by an oxide of iron, into a dark red sand-stone, the grains of silex in which are of very unequal sizes, even in the same specimen. This stone is called car-stone in some places, and was for many years, previous to the roads in Woburn being undertaken by the late duke's agent, the sole material used on the roads; and the grinding of it, and subsequent washing away of the ferruginous cementing matter by the rains, occasioned two-thirds in length of those deep, loose sandy roads, (which were the remark and terror of travellers who valued their horses, under the name of the Woburn Sands,) across tracts of alluvial clay, where not the least sand is to be found but what has been brought thither, when in the form of car or sand-stone. It is much to be lamented, that this absurd practice still continues in the parishes of Wavendon and Broughton, between Woburn and Newport Pagnel, instead of searching for and clean sifting the quartz and flint gravel, which is to be had in sufficient plenty.

The most remarkable feature of the Woburn-sand strata, are the beds of fullers-earth which they produce near the bottom. It is believed, that in whatever part of the basset of this sand across England a search is made, the fullers-earth will be found, but generally in thin and foul beds, of no value, and also the silicious or cherty-stone of a peculiar nature and fracture which lies beneath it, and the specimens of petrified wood which also abound in the same situation; but over several hundred acres at the least, on the north-west of Woburn, both in Aspley-Guise parish in Bedfordshire, and in Wavendon in Buckinghamshire, this substance is found from five to seven or eight feet thick, between the beds of sand or sand-stone, perfectly free from any extraneous matter. The original and most extensive workings, which seem of great antiquity, were on Aspley Common Heath, and in Aspley-Wood in the same parish; and hence it was truly said, that these celebrated pits were in Bedfordshire, but at present the only pit (or rather mine, as it is now worked) which is in use, is near Hogstyend, in a point of land in Wavendon, which bends round in rather an extraordinary way into the parish of Aspley. The demand for this article,

once so highly prized by the clothiers of this and other countries, has dwindled almost to nothing within twenty or thirty years past. The very great accumulation of alluvial clays on the Caxton range in Cambridgeshire, and these again between Leighton-Busard and Winslow in Buckinghamshire, almost entirely bury and conceal these sand strata for many miles on each side of Bedfordshire.

The clunch clay, so called by Mr Smith from several thin beds near to its top and to the Woburn or fullers-earth sand, which this clay underlays, of a soft perishable stone, much resembling hurlock, or hard chalk, when fresh dug, is the thickest of the Bedfordshire strata; and by its peculiar property of ending by various steps, or, as it has been termed, feathering out, instead of ending at once in a bold range of hill, (as is the character of many strata to do, like the chalk and the Woburn sand, for instance,) this stratum forms the vale of Bedford, extending for several miles on the south side of that town, to the vale of Newport-Pagnell, which extends in like manner S. and S. W. of that town, to the foot of the sand hills, and most of the flats occupied by the fens of Cambridgeshire and Lincolnshire, as has been noticed by Mr Farey in the *Philosophical Magazine*, vol. xxxvi. p. 105; also in vol. xxxv. p. 259, where this stratum is supposed to produce alum at Whitby and other adjacent parts of Yorkshire. The great thickness of this clunch clay, of a blue or dark colour, perhaps 500 feet, and its peculiar mode of ending, occasions it to occupy near half of the surface of the county of Bedford, from near Aspley-Guise to Everton, and north-west of this. In some parts of this thick stratum, there are beds of bituminous argillaceous schist, which will burn like a very bad coal; and has given rise to an opinion in most of the counties where it ranges, that seams of coal might be discovered at greater depths; but none such exist, nor indeed any of the real indications of coal seams. Near Elston and in Goldington, coal has been suspected to exist, by those unacquainted with the subject. Other beds, very friable and black, which are found in other situations in this stratum, have been mistaken for marle, but found, on trial, to want its valuable qualities, as an ameliorator of the soil. It is perhaps to the basset of these beds, that the "woodland soils" of this county are owing, whose black and friable mould would, at certain seasons, impress a stranger with the opinion of good land; but no sooner does heavy or continued rains come, than the most tenacious paste imaginable is formed; while in every drought after frost, the whole is puffed up like a sponge in lightness, and it is blown away from the roots of the corn by the wind, often to the entire destruction of the crop; and if in this state a sudden shower falls, it washes away this dust before it, into the furrows and ditches, almost in an equal degree. On these soils, and on the colder parts of the alluvial clay, particularly the steep sides of the hills, in the northern and middle parts of the country, there are perhaps 6500 acres of ancient woods, besides about 500 on the sand, and where also extensive plantations of the fir tribes have been made within the last 80 years, and within the last 20 in particular.

The Bedford limestone strata, already mentioned in speaking of that town, are the lowest which appear in Bedfordshire, unless perhaps some of the blue clay which underlays them, may appear in the extreme northern parts of the county. They consist of several

compact beds of stone, with clay, sometimes whitish, but oftener dark blue or black interposed; and are laid bare, or partially cut through, by the excavation of the vale of the Ouse, from near Goldington, N. E. of Bedford town, along all its devious course, to Newport Pagnel, or a little north of it, Stoney-Stratford, and Buckingham. In Puddington, Wimington, Melshburn, Yelding, Dean, and Shelton, the regular basset or out-crop of the Bedford limestone appears, and the excavation of the valley through Risley has also laid it bare therein.

Nearly round the town of Woburn, except on the south side, there ranges an immense fault or gulf in the sand strata, which is close filled up with alluvial clay and chalk ruins, that is in some places 100 yards wide, and goes completely through the sand at least, as is evident from the plentiful springs of water held up within it, (and which doubtless gave rise to the present site of the town,) while without this clay gulf there is dry sand to the depth of 70 or 100 feet, in wells which have been sunk. On the north of this town, and extending downwards to Crawley church and mill, there is a large tract of the strata sunk, from 50 to perhaps 200 feet in some places, below all the surrounding sand, and the clay at its north border.

The Ouse, with the Ivell, the Ouzel, and other small rivers and brooks which fall into it, form the principal waters of Bedfordshire, which is without any natural lakes or artificial reservoirs or ponds of water of any magnitude, except in the parks at Woburn, Wrest, and Chicksands. There are mineral springs at Bromham, Clapham, Cranfield, Holcutt, Oakley, Turvey, Wrest-gardens, &c. but they are little if at all used. The Ouse is navigable for boats up to Bedford, with a branch to Biggleswade, which is intended to be carried up the vale of the Ivell to Shefford, according to an act long since obtained for this purpose. The grand junction canal skirts this county for about 3 miles, near Leighton-Busard, but it can scarcely be said to enter it.

Bedfordshire is within the Norfolk circuit of judges: it is within the diocese of Lincoln, and under the jurisdiction of an archdeacon, and is divided into six deaneries, viz. Bedford, Clapham, Dunstable, Eaton, Fleete, and Shefford; Woburn parish, forming a peculiar jurisdiction under the duke of Bedford, as the lay abbot of Woburn.

It returns two members to serve in parliament, (besides the two for Bedford town,) and contains, according to Mr Lysons, 121 parishes, distributed in 9 hundreds, besides the borough of Bedford, viz. Barford, Stodden, Willey, Biggleswade, Clifton, Wixamtree, Marshead, Redbornestoke, and Flitt: 63 of the parishes are vicarages, and the great tithes of these are principally in lay hands, as the possessions of the suppressed religious houses.

Bedfordshire probably contains about 275,200 acres; its greatest length is about 36 miles, and greatest width about 22 miles. In the year 1801, when the population returns were made to parliament, this county had 11,888 houses which were inhabited, and 185 which were empty: the number of families was 13,980; the number of persons chiefly employed in agriculture was 18,766; persons chiefly employed in trade, manufactures, or handicraft, 13,816; and persons to whom no occupation was assigned, and children, 28,789; the total number of resident individuals being 63,393, of whom 30,523 were males, and 32,870 females. It is supposed that $\frac{1}{6}$ more

of the people of Bedfordshire are serving in the army, militia, navy, marines, and merchants' service; and, from the annual registers of baptisms, it has been calculated, that in 1700 the total population belonging to this county, was 48,500; in 1750, 53,900; and in 1801, 65,500 persons. Whence it appears, that there are in Bedfordshire $5\frac{1}{3}$ persons, and $22\frac{9}{10}$ acres to each inhabited house very nearly. There is more than $4\frac{1}{3}$ acres to each person: and the persons employed in cultivating the soil, are 1 in every $3\frac{3}{8}$ of the whole population; and in trade, manufactures, and handicraft, 1 in $4\frac{7}{12}$ nearly.

From the returns made to parliament in 1776, 1784, and 1805, it appears, that the amount of poor-rates raised in this county, at the first period, was 18,193*l.*:9:4; in the second, 22,658*l.*:1:10; and in the latter, 47,484*l.*:6:7 $\frac{2}{3}$ per annum, making then a rate of about 3*s.* 9 $\frac{3}{4}$ *d.* in the pound, on a rental of 248,600*l.* or 14*s.* 9 $\frac{3}{4}$ *d.* a head on the whole population. Out of the sum raised in 1805, 1175*l.* was expended in removals of paupers, and suits at law respecting their settlements, with the expenses of overseers and other parish officers: also 8430*l.* in county rates and militia expenses, and for the repairs and expenses of the churches, the expenditure by the constables, and the special rates for the repair of the highways, but not including the statute duty or corporation money paid in lieu thereof. The total expenditure for the poor being 38,070*l.* of which 37,944*l.* was distributed to 7276 persons, being parishioners of the county, or to 1 in every $8\frac{2}{7}$ of the individuals belonging to it, their average allowance being 5*l.*:4:5 $\frac{1}{2}$ annually, or 2*s.* per week. Of these paupers, 674 were wholly maintained in workhouses, at the expense of 8440*l.* average 12*l.*:10:5 $\frac{1}{2}$ each, or 4*s.* 9 $\frac{3}{4}$ *d.* per week each person. Besides the above, 761 persons were relieved, who were not parishioners, at the expense of 76*l.* as is supposed. There were at that time 2730 persons associated in 75 friendly societies, or box clubs, in the county, 16 only of which had entered their rules at the quarter sessions, and made their funds disposable by the magistrates of the county; a circumstance which may perhaps be accounted for, from the few among the landed proprietors who here act as magistrates, and the important duties of that office being suffered, in a great measure, to fall into the hands of the clergy. Eight parishes in this county had schools of industry, in which 196 children were taught to work. In Eaton Socon, Risley, and Clophill parishes, the poor were farmed, or maintained by contract.

Formerly it should seem, that wood was cultivated in this country, but it is so long since, that the name is now hardly known among the inhabitants. On the husbandry and state of rural affairs in this county, much valuable information will be found in Thomas Batchelor's *Agricultural Report on Bedfordshire*, printed in 1808. A very small portion of Bedfordshire now remains in the state of common or uninclosed. An agricultural society was established at Bedford in the year 1801, but which seems rather on the decline since 1803.

Mr Benjamin Bevan of Leighton-Busard has for some years kept a meteorological journal, which, with some account of the rain which falls about Woburn, will be found in the volumes of the *Monthly Magazine*. There is a book society at Bedford, and perhaps some others, but there is not in the county any scientific institution.

Bedfordshire, in common with Buckinghamshire and Hertfordshire, formed the habitation of the Cattieuchlani, a British tribe, whose chief was Cassivellaunus, at the time of the Roman invasion under Julius Cæsar.

After the division of this island into five provinces by the Emperor Constantine, about the year 310, Bedfordshire fell into the province called Flavia Cæsariensis. At the establishment of the Mericain kingdom it was included therein, and so continued until the year 827, when, in common with the rest of the kingdom, it became subject to Egbert king of the west Saxons. Upon the subdivision of the kingdom into shires, hundreds, and tithings, this county was formed as it at present remains. It is crossed by two Roman roads, the Watling Street, which enters it at Dunstable, and leaves it between Heath and Potsgrave; and the Ichnild way, which enters it in Eaton Bray, and leaves it south-west of Barton. At Sandy, near Potton, is a Roman encampment called Salenæ; and Maiden Bower, north west of Dunstable, is said to be another. At Totternhoe, near this, are two hills which have been fortified, and another at Ridgemont. See Britton's *Beauties of England and Wales*, vol. i.; Lyson's *Magna Britannia*, vol. i.; and Batchelor's *Agricultural Report on Bedfordshire*. (c)

BEDOUINS, or BEDOWANS, the wandering tribes of Arabs that inhabit the deserts of Arabia, and other uncultivated parts of Asia and of Africa, which have been peopled from the original Arabian stock. Their name, which in Arabic is *Bedouai*, denotes wanderers, or inhabitants of the desert, being derived from *bid*, a desert. They are supposed to be descended from Ishmael, and are the legitimate representatives of the *Arabes Scenitæ*, or tented Arabians of the ancients. They never dwell in houses, but pitch their tents on spots of the desert which have springs and a little pasturage, sufficient to support their herds of camels, goats, sheep, or horses; and migrate from place to place, as their wants and inclination prompt them, taking care, however, not to encroach upon the district belonging to other tribes of the desert.

Although the Bedouins are divided into independent tribes or communities, which are frequently hostile to one another, they may still be considered as forming but one nation; as they have the same common origin, the same customs and religion, and speak the same language. Each tribe is composed of one or more principal families, the chiefs of which are called *scheiks*, or lords. Of these scheiks, one assumes the supreme command, both in war and in peace, and is sometimes called *emir*, or prince. His authority, however, is rather patriarchal than despotic; and he is desirous of extending his power, by forming alliances with the chiefs of smaller tribes, who are too weak to maintain their own independence, and whom he attaches to himself by supplying their wants. The tribes are distinguished by the names of their respective chiefs, or by that of the ruling family; and when they speak of any of the individuals that compose them, they call them the *children* of such a chief; as for example, *Beni Temin*, *Oulad Tai*, the children of Temin and of Tai. The tribes of the deserts of Arabia, properly so called, have descended by an uninterrupted succession from the remotest ages: but the African tribes are of less ancient origin, being posterior to the conquests in that country, by the caliphs, or successors of Mahomet.

The description of the ancestors of the Bedouins, given by Diodorus Siculus, 1800 years ago, is by no means inapplicable to their present state. "The wandering Arabs," says that author, (c. 19.) "dwell in the open country, without any roof. They themselves call their country a solitude. They do not choose for their

abode, places abounding in rivers and fountains, lest that allurements alone should draw their enemies into their neighbourhood. Their law, or their custom, forbids them to sow corn, to plant fruit-trees, to make use of wine, or to inhabit houses. He who should violate these usages would be punished infallibly with death; because they are persuaded, that whoever is capable of subjecting himself to such inconveniences, would soon submit to a master, in order to preserve them. Some lead their camels to graze, some their sheep. The latter are the wealthiest; for, besides the advantages they derive from their flocks, they go to sell in the sea-ports, frankincense, myrrh, and other precious aromatics, which they have received in exchange from the inhabitants of Arabia Felix. Extremely jealous of their liberty, at the news of the approach of an army, they take refuge in the depth of the deserts, the extent of which serves them as a rampart. The enemy, in fact, perceiving no water, could not dare to traverse them, whilst the Arabs, being furnished with it, by means of vessels concealed in the earth, with which they are acquainted, are in no danger of this want. The whole soil being composed of clayey and soft earth, they find means to dig deep and vast cisterns, of a square form, each side of which is the length of an acre. Having filled them with rain-water, they close up the entrance, which they make uniform with the neighbouring ground, leaving some imperceptible token, known only to themselves. They accustom their flocks to drink only once in three days, so that when they are obliged to fly across these parched sands, they may be habituated to support thirst. As for themselves, they live on flesh and milk, and common and ordinary fruits. They have in their fields the tree which bears pepper; and a great deal of wild honey, which they drink with water. There are other Arabs who cultivate the earth. They are tributary, like the Syrians, and resemble them in other respects, except that they do not dwell in houses. Such are very nearly the manners of this people."

The Bedouins of Arabia justly boast of their independence, since they have never been conquered; nor have they assimilated themselves with other nations by making conquests. The revolution effected by Mahomet had little influence upon these wandering tribes; and we find the prophet, in his *Koran*, styling them rebels and infidels. They have indeed adopted the Musulman faith, but their manner of life, and the places in which they dwell, effectually secure them from foreign dominion. To figure to ourselves the country which they inhabit, we must, says M. Volney, imagine a sky almost perpetually inflamed, and without clouds; immense and boundless plains, without houses, trees, rivulets, or hills; where the eye frequently meets nothing but an extensive and uniform horizon like the sea, though in some places the ground is uneven and stony. Almost invariably naked on every side, the earth presents nothing but a few wild plants thinly scattered; and thickets, whose solitude is rarely disturbed but by antelopes, hares, locusts, and rats. Such is the nature of nearly the whole country, which extends 600 leagues in length, and 500 in breadth, stretching from Aleppo to the Arabian Sea, and from Egypt to the Persian Gulf.

The soil, however, varies considerably in different places, and this variety occasions corresponding differences in the manners and condition of the Bedouins. In the more sterile districts, the tribes are feeble and thinly scattered. This is the case in the desert of Suez,

that of the Red Sea, and the interior of the great desert called the Najd. In general, the Bedouins are a small, meagre, and tawny race; but those who inhabit the heart of the desert are much more so than those who dwell on the frontiers of the cultivated country. When, in the time of the Sheik Daher, some of the horsemen of a remote tribe came to visit Acre, every body viewed with surprise this meagre, swarthy, and diminutive race. Their withered legs were composed only of tendons, and had no calves. Their bellies seemed to cling to their backs, and their hair was frizzled almost as much as that of the negroes. They, on the other hand, were no less astonished at every thing they saw; they were unable to conceive how the houses and minarets could stand erect, or how men ventured to dwell beneath them, and always in the same spot; but, above all, they were in an ecstasy on beholding the sea, nor could they comprehend what that mighty desert of water could be. The Bedouins who are settled near towns and fertile provinces, enjoy many more comforts than those of the desert, and till the ground as well as tend their flocks. They are, however, reduced, in some measure, to a state of dependence on the sovereigns of the adjacent country. But the Bedouins on the confines of the desert have maintained their liberty unimpaired, and preserve their national character in its greatest purity. Of these, the tribe denominated "Beni Khaleb" is one of the most powerful, on account of its conquests and wealth, and the number of other tribes subjected to it. It has advanced from the desert of Najd to the sea, and conquered the country of Lachsa. The tribe of "Koab" inhabits north of the Persian Gulf, and has possessions in the province of Chusistan, in Persia, where there are five different considerable tribes of Bedouins. The tribe "Beni Lam" dwells between Kerne and Bagdad, upon the banks of the Tigris, and receives duties upon goods carried from Bassora to Bagdad; sometimes pillaging caravans. The "Montefidhi," or "Montefik," is the most powerful tribe north from the desert, with respect to extent of territory, and the number of subaltern tribes acknowledging their authority. They possess all the country on both sides of the Euphrates, from Kerne to Ardic. In Egypt there are various tribes of Bedouins, which migrate every year from the heart of Africa, after the inundation of the Nile, to profit by the fertility of the country, and in spring retire again into the depths of the desert. There are others which are stationary, and farm lands, which they sow, and annually change. Mr Sonnini speaks highly in praise of the stationary Bedouins of Egypt. The males, he says, are in general handsome; they live to be very old, and, in their advanced age, are conspicuous for a respectable and truly patriarchal appearance. The women, when young, are not destitute of beauty, notwithstanding their tawny hue, and those disfiguring compartments which they impress on the lower part of their faces with a needle and a black dye. He found a very singular opinion prevalent with a tribe which he visited, which tradition had rendered sacred among them. They asserted, that their ancestors were Europeans, and Christians, who, having been shipwrecked on the coast of Egypt, were plundered, and reduced to live in the desert. The whole, however, that they retained of the pretended Christianity of their forefathers, was the sign of the cross, which they made with their fingers, or traced in the sand. *Travels in Egypt*, ch. xxv.

The customs and manners of life of all the Bedouins, whether African or Asiatic, are very nearly the same, and present a lively picture of the rude simplicity of the pastoral stage of society. The camps of the Bedouins are formed in a kind of irregular circle, composed of a single row of tents, with greater or less intervals. These tents are made of goats or camels hair, black or brown, or striped black and white, by which they are distinguished from those of the Turcomans, which are white. They are only five or six feet high, stretched on three or four pickets, so that at a distance they appear like a number of black spots, or mole-hills. The length of these tents is much greater than their breadth; and they are entirely open on one of their long sides, being that from which the wind most rarely blows. The tent of the scheik is distinguished from the rest by nothing but a plume of ostrich feathers placed at the top. Each tent inhabited by a family is divided by a curtain into two apartments, one of which is appropriated to the women. The empty space within the circle serves to fold their cattle every evening. In these tents the Bedouins, when they go to rest, stretch themselves out upon the ground, without bed, mattress, or pillow; wrapping themselves in their hides or blankets, and lying upon a mat, wherever they can find room. They have no entrenchments, nor any advanced guards except their dogs; their horses remain saddled, and ready to be mounted upon the first alarm; but being utter strangers to order and discipline, their camps are always open to surprise, and then afford no sufficient means of defence.

The wealth of a Bedouin is extremely circumscribed. It generally consists of a few male and female camels; some goats or sheep, and poultry; a mare with her bridle and saddle, which he prefers to a horse, because she seldom neighs, is more docile, and yields him milk, which occasionally satisfies both his hunger and thirst in the desert; add to this his tent; a lance 16 feet long; a crooked sabre; a rusty musket, or matchlock; a pipe; a portable mill; a pot for cooking; a leathern bucket; a small coffee-roaster; a straw mat, which serves equally for a seat, a table, and a bed; some clothes which are put up in leathern bags; a mantle of black woollen; a few glass or silver rings which the women wear upon their legs or arms; and perhaps a little money which he buries. The wealth of a scheik is somewhat more considerable. M. Volney resided with one in the country of Gaza, about the end of 1784, who was reckoned very great and powerful; and whose expenditure he compares to that of an opulent farmer; and estimates his effects, consisting of a few pelisses, carpets, arms, horses, and camels, at about 50,000 livres, or 2000*l.* sterling. With such scanty possessions, and dwelling in a desert, we cannot suppose that the Bedouins live very luxuriously, or even plentifully. The greater part of them, indeed, may be said to lead lives of habitual wretchedness and famine. The length to which they are able to carry their abstinence by the force of habit and the impulse of necessity, is truly astonishing. The whole food consumed by the greatest part of them does not usually exceed six ounces a day, and that too of the simplest kind. A few dates soaked in butter, a little sweet milk or curds, will serve a man for a whole day; and he esteems himself happy when he can add a small quantity of coarse flour, or a little ball of rice. Meat is used only at the greatest festivals; and they never kill a kid but for a marriage or a funeral. The scheiks, indeed,

can afford to live more generously, and have a better appearance in their persons, in consequence of their more comfortable fare; but in times of dearth, the vulgar, always half famished, do not disdain the most wretched kinds of food; and eat locusts, rats, lizards, and serpents, broiled on briars. "An Arab," says M. Jackson, "will go 50 miles a day without tasting food, and at night will content himself with a little barley meal mixed with cold water. The term that is applied to the richest men among the Arabs is, that they eat meat every day." *Account of the Empire of Morocco*, p. 228.

When we consider the poverty and necessities of the Bedouins, and their wandering manner of life, we shall not be much surprised at their being habitual plunderers, and formidable enemies to all who have occasion to traverse the desert. But they never murder those whom they rob, unless travellers, in their defence, should chance to kill a Bedouin; and then they are eager enough to revenge his death, and will not be satisfied without blood for blood. On many occasions, the caravans which pass at stated intervals through the territory of a scheik, pay a stipulated sum as a ransom, or safeguard; and an agreement of this kind is always religiously kept by the Arabs. The different tribes of Bedouins have frequent hostilities with each other; but their contests are seldom protracted or bloody. When the cause of offence is made known to a tribe, they immediately mount their horses, and seek the enemy; when they meet, they enter into a parley, and the dispute is frequently compromised; if not, they attack either in small bodies, or man to man. They encounter each other at full speed with fixed lances, which they sometimes dart, notwithstanding their length, at the flying enemy. The victory is generally decided at the first shock, and the vanquished fly off at full gallop, over the naked plains of the desert. The tribe which has been defeated strikes his tents, removes by forced marches to a distance, and seeks an asylum among its allies. Dissensions, however, are sometimes perpetuated by the slaughter that is made on these occasions; it being an established principle among the Bedouins, that the blood of every man who is slain must be avenged by that of his murderer. This vengeance is called *tar*, or retaliation; and the right of exacting it devolves on the nearest of kin to the deceased. If any one neglects to seek his retaliation, he is for ever disgraced; he therefore watches every opportunity of revenge; and if his enemy perishes in any other way, he seeks satisfaction by inflicting vengeance on the nearest relation. These animosities are transmitted from father to children, and never cease but by the extinction of one of the families, unless they agree to sacrifice the criminal, or purchase the blood at a stated price, in money or flocks.

The authority of a scheik, or chieftain of a tribe, is undefined, and therefore, in some measure, arbitrary; the people, however, are consulted in all affairs of moment, and every thing is decided upon by the voice of the majority. The dignity of scheik is hereditary, but not confined to the order of primogeniture; the petty scheiks, who form the hereditary nobility, chuse the grand scheik out of the reigning family, without considering his immediate relationship to his predecessors. Little or no revenue is paid to the grand scheik; in fact, his dignity subjects him to a very great expense; for he defrays the charges of all who arrive at or leave the camp. Adjoining to his tent is a large pavilion for the

reception of all strangers and passengers; and in which are held the assemblies of the principal men to determine upon all important affairs. Here he entertains his guests with coffee, bread baked on the ashes, rice, and sometimes roasted kid or camel; the females of his family performing with their own hands the office of preparing the repast. On his generosity and hospitality, depend, in a great measure, his credit and his power; for hospitality is a virtue in the highest degree prized by the necessitous Bedouin. So rapacious without his camp, he no sooner arrives there, than he becomes liberal and generous. The little he possesses, he is ever ready to divide. When he takes his repasts, he seats himself at the door of his tent, in order to invite passengers; a generosity which he does not consider as a merit, but merely as a duty; and he, therefore, readily takes the same liberty with others. The rights of hospitality with the Bedouin, include also the rights of asylum, and of friendship. If the Bedouin has consented to eat bread and salt with his guest, nothing in the world can induce him to betray him. Nay, should a stranger, or even an enemy, but touch the tent of a Bedouin, from that instant his person becomes inviolable. It would be reckoned a disgraceful meanness, an indelible shame, to satisfy even a just vengeance at the expense of hospitality.

In this sacred regard to the rights of hospitality, and in various other particulars, the character of the Bedouin nearly resembles that of the savages of North America. The Bedouin, however, has nothing of the ferocity of the native American; for though frequently experiencing the extremity of hunger, the practice of devouring human flesh is utterly repugnant to his nature; and he neither tortures, nor puts to death the captives that fall into his power. The occupations of the Bedouin, who is by necessity a shepherd, as he dwells in regions where there is no employment for the hunter or fisherman, tend to foster in him this superior degree of humanity; while those of the American, who busies himself entirely in the pursuit and destruction of game, encourage rather an unfeeling and sanguinary disposition of mind.

In many particulars there is a singular resemblance between the character and manners of the Bedouins, and those of the Scottish Highlanders, at the period when the feudal authority of their chieftains existed in full vigour; and the clans chiefly occupied themselves in a predatory warfare upon one another, or upon the more peaceful inhabitants of the low country. We happen to have access to some interesting reports respecting the state of the Highlands, made in the years 1724, 1725, and 1727, by the celebrated General Wade, which we believe have never yet been published, although they contain much curious observation. It will, doubtless, gratify our readers to be furnished with an extract from these reports, by which they may estimate the justness of the parallel which we have drawn between the character of the wild Highlander and that of the wild Arab.

“The Highlanders,” says General Wade, “are divided into tribes or clans, under lairds or chieftains, (as they are called in the laws of Scotland;) each tribe or clan is subdivided into little branches sprung from the main stock, who have also chieftains over them; and from these are still smaller branches of fifty or sixty men, who deduce their original from them, and on whom they rely as their protectors and defenders. The arms they make use of in war are, a musket, a broad

sword and target, a pistol, and a duk or dagger hanging by their side, with a powder-horn, and pouch for their ammunition. They form themselves into bodies of unequal numbers according to the strength of their clan or tribe, which is commanded by their respective superior or chieftain. When in sight of the enemy, they endeavour to possess themselves of the highest ground, believing they descend on them with greater force. They generally give their fire at a distance, then lay down their arms on the ground, and make a vigorous attack with their broad swords; but, if repulsed, seldom or never rally again. They dread engaging with the cavalry, and seldom venture to descend from the mountains, when apprehensive of being charged by them.

“On sudden alarms, or when any chieftain is in distress, they give notice to their clans, or those in alliance with them, by sending a man with what they call the *fiery cross*, which is a stick, in the form of a cross, burnt at the end,—who send it forward to the next tribe or clan. They carry with it a written paper, directing them where to assemble; upon sight of which, they leave their habitation, and with great expedition repair to the place of rendezvous, with arms, ammunition, and meal for their provision.

“The imposition commonly called *black-mail*, is levied by the Highlanders on almost all the low country bordering thereon. But as it is equally criminal by the laws of Scotland to pay this exaction, or to extort it, the inhabitants, to avoid the penalty of the laws, agree with the robbers, or some of their correspondents in the lowlands, to protect their houses and cattle, who are in effect but their stewards, or factors; and as long as this payment continues, the depredations cease upon their lands; otherwise the collector of this illegal imposition is obliged to make good the loss they have sustained. They give regular receipts for the same safe-guard money; and those who refuse to submit to this imposition are sure of being plundered.

“Those who are robbed of their cattle, (or persons employed by them,) follow them by the track, and often recover them from the robbers, by compounding for a certain sum of money agreed on. But if the pursuers are armed, and in numbers superior to the thieves, and happen to seize any of them, they are seldom or never prosecuted, the poorer sort being unable to support the charge of a prosecution. They are likewise under the apprehension of becoming the object of their revenge, by having their houses and stacks burnt, their cattle stolen or hocked, and their lives at the mercy of the tribe or clan to whom the banditti belong. The richer sort (to keep, as they call it good neighbourhood,) generally compound with the chieftain of the tribe or clan for double restitution, which he willingly pays to save one of his clan from prosecution; and this is repaid him by a contribution from the thieves of his clan, who never refuse the payment of their proportion to save one of their own fraternity. This composition is seldom paid in money, but in cattle stolen from the opposite side of the country, to make reparation to the person injured.”

The situation of the Bedouins owes some of its most material comforts to the camel, an animal which nature seems to have expressly designed for inhabiting the desert, and enduring the hardships and privations which are inseparable from such a mode of life. He is of a form muscular and robust, without having any superfluous flesh to support: on his legs and thighs we find

absolutely nothing but the muscles indispensable for motion. He is furnished with a strong jaw, that he may grind the hardest aliments; and with a straitened and ruminating stomach, that he may not consume too much. His foot is lined with a lump of flesh, which, sliding in the mud, and being in no way adapted to climbing, fits him for a dry, level, and sandy soil like that of Arabia. Nature has also evidently destined him to slavery, by refusing him every sort of defence against his enemies. To preserve the species, therefore, she has concealed him in the depth of the vast deserts, where the want of vegetables can attract no game, and whence the want of game expels every voracious animal. Here his abstinence enables him to support his strength on the scanty herbage which the arid soil produces; and he is capable of existing without water for several days together. Reduced to the domestic state, he has rendered habitable the most barren soil that the world contains; and is alone sufficient for all his master's wants. The milk of the camel nourishes the family of the Arab, under the various forms of curd, cheese, and butter; and his flesh furnishes a repast upon extraordinary occasions. Slippers and harness are made of his skin, tents and clothing of his hair. Heavy burdens are transported by his means; and when the earth denies forage to the horse, the camel, for so many advantages, seeks no other recompence than a few stalks of brambles or wormwood, and pounded date kernels.

The ordinary rate of motion of the camel greatly exceeds the journeying pace of the horse; but there is a peculiar species called the *desert camel*, of which the velocity is so great, as almost to exceed credibility. Mr Jackson, in his recent account of Morocco, has given the following account of the desert camel of the Sahara, in Africa. "Nature, ever provident, and seeing the difficulty of communication, from the immense tracts of desert country in Sahara, has afforded the Saharanans a means, upon any emergency, of crossing the great African desert in a few days. Mounted upon the *heirie*, or desert camel, (which is in figure similar to the camel of burden, but more elegantly formed,) the Arab, with his loins, breast, and ears bound round, to prevent the percussion of air proceeding from a quick motion, rapidly traverses, upon the back of this abstemious animal, the scorching desert, the fiery atmosphere of which parches and impedes respiration, so as almost to produce suffocation. The motion of the *heirie* is violent, and can be endured only by those patient, abstemious and hardy Arabs, who are accustomed to it. The most inferior kind of *heirie* are called *talatayec*, a term expressive of their going the distance of three days journey in one; the next kind is called *sebayec*, a term appropriated to that which goes seven days journey in one, and this is the general character: there is also one called *tasayec*, or the *heirie* of nine days; these are extremely rare." p. 39, 40. The swiftness of this useful animal, Mr Jackson informs us, is thus described by the Arabs in their figurative manner. "When thou shalt meet a *heirie*, and say to the rider *Salen-Aick*, 'peace be between us;' ere he shall have answered thee, *Alick-Salem*, 'there is peace between us,' he will be afar off, and nearly out of sight, for his swiftness is like the wind."

The arts of the Bedouins are few and simple, and consist in weaving their clumsy tents and clothing, and in making mats and butter. They preserve their butter in leathern bags, and their water in goat skins. Their

hearth consists of a hole in the ground, laid with stones, and covered with an iron plate, on which they bake their bread, made into small cakes. In their excursions they carry with them a supply of meal; and their other provisions are, dates, milk, cheese and honey. Their whole commerce extends only to the exchanging of camels, kids, stallions, and milk, for arms, clothing, a little rice or cotton, and some money, which they buy. They are totally ignorant of science, and nothing is more uncommon among them than to know how to read. Their only literature consists in singing love-songs, or in reciting tales and histories, in the manner of the *Arabian Nights Entertainments*. For such stories they have a peculiar passion; and in the evening they seat themselves on the ground, at the door of their tents, or under cover, if it be cold; and there, ranged in a circle, round a small fire of dung, with their legs crossed, and their pipes in their mouths, after indulging for some time in silent meditation, they amuse themselves with the recital of tales of this kind. They profess the religion of Mahomet, but are far from being strict in the observance of its ceremonies, or fervid in their professions of devotion. They excuse themselves for this laxity, by demanding, "How shall we make ablutions, who have no water? How can we bestow alms, who are not rich? Why should we fast in the Ramadan, since the whole year with us is one continued fast? And what necessity is there for us to make the pilgrimage to Mecca, if God be present every where?"

We shall conclude this account of the Bedouins, with extracting from the Travels of Sonini in Egypt, a very lively and interesting detail of a rencounter which that traveller had in the desert with a troop of these marauders, in consequence of which he had an opportunity of seeing the peculiarities of their character in a very striking light. He was on his way from Alexandria to Cairo, under the guidance and safeguard of Hussein, who was scheik of a tribe of half civilized Bedouins stationed not far from Alexandria, and had entered the desert which skirts the famous lakes of natron. "I staid some days," says our traveller, "near the lakes, the borders of which I traversed; at length we resumed our journey, continuing our course to the south-west. The sand over which we travelled was completely covered with hardened natron, which rendered our progress toilsome and fatiguing, both to us and our beasts. We arrived within a short distance of a large square edifice, in which a few Coptic monks live shut up from the world. I do not think that there is upon earth a more horrible or repulsive situation than this sort of convent. Built in the midst of the desert, its walls, though very lofty, are not distinguishable at any considerable distance from the sand, of which they have the reddish tinge, and bare aspect. There is no apparent entrance; no tree, no plant of any height, is seen around it; no path leads to it; no trace of human footstep is observable in its vicinity; and, if a few be imprinted, they are soon covered by the sand, or obliterated by the tread of wild and ferocious beasts, the proper inhabitants of these frightful solitudes.

"We were about 500 or 600 paces from this dungeon. Hussein had advanced before us, to obtain our admission into the convent, which is to be procured with difficulty. I was some way from him, and the rest of our company was at a considerable distance. A troop of Bedouins, on horseback, suddenly issued from behind the walls. At first I did not distinguish them, amid

the clouds of dust they raised; but, as soon as they were discernable, I perceived both their number, and what they were. Instantly I turned about my horse's head, and being mounted on an excellent courser, which carried me with too much speed for them to overtake me, soon joined my companions, who had likewise perceived the troop from the backs of their camels. I found them on foot, drawn up in a close body; leaped off my horse; and exhorted them to defend themselves with vigour. We were six in all, but on three of the number little dependence was to be placed. From two of the natives of the country we could not expect much; and the draughtsman, young and inexperienced, scarcely knew how to fire a gun.

The firmness of a handful of men alone in the midst of a sandy plain, and exposed on all sides, checked a squadron of Bedouins amounting to near a hundred. Though they came towards us at full gallop, they stopped suddenly about a hundred paces off, and cried out to us not to fire. I answered with telling them not to advance. For some moments they remained in a sort of hesitation, during which we observed them consulting together; at length they separated into four bands, three of which set off at full gallop, and stationed themselves on our flanks and in our rear. This manœuvre, which it was impossible for us to prevent, disconcerted my two soldiers; and all that I could urge was incapable of prevailing on them to resolve to stand on their defence. We had good fusils, and a considerable quantity of cartridges. I knew that the Bedouins would take flight, as soon as they saw a few of their party drop; and I was certain, that our first fire must bring down several. It is true, I did not consider that we were in the midst of a vast solitude, and that, if our enemies had fled, it would only have been to return again speedily by thousands, overpower us by their numbers, and massacre us all, in revenge for the death of their comrades. I flung down my fusil with vexation at being forced to yield to such robbers.

"They were soon upon us, and, without taking time to alight, pillaged us in the twinkling of an eye. Money, arms, effects, garments, provisions, were all taken. They left me my long under vest and my breeches; my companions were stripped of every thing but their shirts. My turban had been taken; my head, shaved and bare, was scorched by the fervency of the sun, and ached intolerably. I covered it as well as I could with both my hands, but this would not alleviate the pain. The spoil was spread out upon the sand; a score of Arabs on foot, whom we had not perceived, as they had concealed themselves behind a heap of stones, joined the others; and they all fell to dividing the plunder, not without obstreperous disputes.

"Our different situations would have formed a striking subject for a picture, under the hand of an able artist. In one place you might have seen, disputing over the booty, the band of robbers, covered with dust, some of black, others of tawny complexions, and their countenances dried up like the sands, which their robberies render still more dismal: in the midst of them my old servant, coolly endeavouring to recover from them some small portions of our spoil, and occasionally dealing a blow with his fist to attain his object. In the foreground, the grenadier, motionless and disconcerted; the two Egyptians staring stupidly on each other; me, at a distance, biting my fingers, with a look of indignation and chagrin; and, in the last place, the draughtsman,

crying bitterly, and answering me with sobs, when I went up to him, to ask him if he had received any hurt: 'No, sir, but what shall we get to eat now?'

"Tired of being the spectator of a scene in which it was useless for me to take a part, I proceeded towards the monastery, hoping to find Hussein, who had repaired thither; when I heard myself called, and presently felt myself seized by the arm. It was the chief of the robbers, an Arab of the desert of Nubia, for his face was as black as a negro's. He led me back, without saying a word, into the midst of the troop. I imagined that he was desirous of the garments they had left me, or that, on deliberation, he had resolved to take away my life. How great was my surprise, when I found this chief carefully inquiring what clothes and effects belonged to me; and, after having acted as my valet-de-chambre a little too roughly in undressing me, now taking upon himself the same office, but with more civility, in assisting me to put on the different parts of my dress; returning me my purse, and restoring my arms! Other Bedouins performed the same office to my companions, equally astonished at so singular and unexpected an adventure.

"This was the fruit of Hussein's spirited conduct. While he was near the walls of the convent, to which he had repaired with his fusil slung over his shoulder, some of the Arabs set off to detain him. They had seized his arms; but Hussein, after a long dispute, succeeded in getting up behind one of the Bedouins, and being conveyed to the place where the whole troop was, "Arabs!" said he, addressing himself to the chiefs, "you have stripped a man confided to my protection, and for whom I have pledged my own head; a man with whom I have eaten, who has slept under my tent, and who has become my brother. I can never again enter that tent; I dare not show my face again in the camp; I must renounce the pleasure of ever more embracing my wife and children. Arabs, take away my life, or restore all that belongs to my brother." This speech, which was accompanied with a look of firmness and a tone of resolution, made some impression on the minds of the Bedouins. Hussein had snatched his fusil out of the hands of him who held it, and, while waiting till they had taken their resolution, presented it to the chief commander of the robbers, determined to shoot him in case of a refusal, and thus expose himself to be massacred, rather than consent to our suffering the least injury. Our conductor was well known; they were aware, that his resolute character would lead him to carry his threats into execution; thus, partly through fear, partly through deference, the black chief consented to restore all that was taken from me: and this was done with truly admirable fidelity. It is true, every thing that appeared valuable in the eyes of him who had taken it, required to be particularly claimed; but when the chief insisted upon it, it was produced; and this discipline among people, and in a place where we could not have expected to find an instance of it, appeared to me highly astonishing. The chief came to ask me what was missing still; on my naming an article, he mounted on a little eminence, and cried, "Arabs, such a thing is not restored; let it be brought." If the person who had it was not prompt in his obedience, he added, "Come, Arabs, no delay;" and it was delivered to me immediately. The chief then mentioned another article that had been stolen, and it was restored to me in the same manner.

Two hours were thus spent before the inventory of my effects was gone through. Every thing was restored to me except my money, of which I received only a small part. This, however, was not the fault of the two scheiks. Hussein, in particular, insisted on my counting in his presence the sequins that had been returned. The Arabs, to whom my purse appeared a good prize, and who had shared the chief part of its contents, waited till I had finished counting them with some uneasiness, which was quickly removed on my declaring that I had all my money. Thinking myself happy to come off so well, I had voluntarily sacrificed two-thirds of what I possessed, that I might not incur the hatred of the honest robbers that surrounded me, and expose myself to their vengeance. These banditti thought it not sufficient to appear just, they would also be polite. The chief brought me his horse, and insisted on my mounting it, to ride the little distance from the place we were to the monastery, while he attended me on foot. Some others of the Arabs paid the same respect to my companions, each of them walking, in like manner, by the side of his horse. When we came near the walls, we saw some baskets of bread, and wooden dishes of lentils, let down by ropes. Seating ourselves on the ground, in a circle, we ate up this provision with people who just before were our enemies. After our repast was finished, some of them came up to me with frankness,

and even with a sort of cordiality, thanking heaven that no injury had befallen me; with a tone of concern for my temerity in travelling through a desert, which, by their own confession, was the resort only of thieves and robbers. Above all, they did not forget to say their prayers with great devotion, after they had rubbed their arms and legs with sand, for want of water, to perform the ablutions prescribed by their law. Mahomet, an Arab himself, was aware of the circumstances in which his followers would frequently find themselves in the desert, and accordingly directed them to make use of sand instead of water.

"I learned afterwards, that these Arabs had been informed of our journey, and that they had watched our steps from its commencement. They had been under the walls of the monastery ever since three o'clock in the morning, and had acquainted the monks, that they would have a visit from some Franks in the course of the day. To the very moment when they perceived us, they had been concerting the manner in which they might attack us with least risk; for they were not without apprehensions, as they knew that we were well armed." See Sonini's *Travels in Egypt*, c. xxvii. See also Volney's *Travels in Egypt and Syria*; Savary's *Letters on Egypt*; Neibuhr's *Travels through Arabia, &c.*; and Jackson's *Account of the Empire of Morocco*. (n)

BEE.

This is a very numerous genus of insects, on which we have already made some general remarks under the article *APIS*, the generic name. Here we shall confine our observations chiefly to the honey bee, (*Apis Mellifica*), treating, in the first place, of its nature and properties; and, secondly, laying down those rules which must guide the cultivator in his views to convert the labours of the animal to his own advantage. It is indispensable, however, that he should previously become acquainted with the natural history of the bee, otherwise he will often find his object fail, without being able to assign a reason; and if he does render himself master of it, he will remedy many unexpected disasters by simple and unerring expedients.

Bees have attracted an uncommon share of attention in all countries, and in every age. Their minuteness, numbers, habits, and the luxuries we derive from their united industry, have, from periods of the most remote antiquity, been the fertile source of admiration. Hence have resulted innumerable inquiries, as well for the elucidation of science, as for personal gratification and pecuniary advantage. But, unlike those subjects on which long and patient investigation are bestowed, the obscurities attending the nature of bees seemed to increase in proportion to the observer's anxiety to unveil them, and, at the end of many years, few indisputable facts have been ascertained by individuals. Errors have thence accumulated on errors; imagination has magnified deceitful appearances into certainties, by which even experienced naturalists have been deluded; and most of the treatises published, under the pretence of instructing, serve only to lead the unskilful into the belief of absurd and fallacious doctrines. Nevertheless there are some good authors, who have seen without prejudice, and have related without exaggeration, such as

Swammerdam, Maraldi, Reaumur, Bonnet, Schirach, and Huber. We shall avail ourselves of their observations, and endeavour, from these, and our own practical remarks, to select what has been fixed by experiments—rejecting the fabulous accounts of others.

I. NATURAL HISTORY AND ECONOMY OF THE HONEY BEE.—The honey bee is either wild or domesticated, and consists of numerous societies, composed of from 10,000 to 30,000, perhaps 40,000 or 50,000 individuals. In the former state, it inhabits the woods, in clefts of trees, and, it may be, the cavities of rocks also: in the latter, it is kept by us in wooden boxes, or coverings of straw or osiers, commonly called *hives* in English, but more definitely *skeps* in the Scottish language, or old English: for, strictly speaking, *hive* signifies the covering and its colony; and *swarm*, that portion of the bees which leaves the parent stock at a certain season of the year, before it is lodged under our care. Each hive, by which we understand the whole colony, contains three different kinds of bees; females, males, and workers. The females, of which not more than one can ever live in all the great population of a hive, are called *queens*; the males, of which there are hundreds, and sometimes thousands, are called *drones*; and the remainder are denominated *workers*, or *neuters*, from being supposed to belong to neither sex. They are the operative part of the community; for, while the female gives birth to the whole young, and the males perform no functions but perpetuating their race, the workers collect the honey, form the wax, build the combs, watch over the growth of the young, and supply their necessities.

We shall not dwell on the anatomy of the bee, concerning which Swammerdam and Reaumur have so

largely written; but the use to which the animal can convert some of its organs, requires a brief explanation of their structure. A bee has four wings and six legs; its abdomen consists of several scaly circular rings, connected by membranes; the last is armed with a sting; and the head is provided with a proboscis, and two mandibles, in addition to a real mouth, which the animal has likewise. The body is totally covered with hair, which is not to be considered an indifferent character; for each separate hair, viewed with a microscope, appears a plant in miniature, with a stem and branches; and the small particles of pollen, shaken off by the motion of a bee in a flower, are arrested by the hairs, and then collected into pellets with its limbs. In the third pair of these limbs is a small hollow, to which the pellets are fixed; and part of the second pair is provided with what resemble brushes, for brushing off the pollen. The proboscis is the principal organ employed in collecting the honey; when inactive, it is folded under the head, and defended by a scaly sheath, or covering. When employed, it is extended, and the animal apparently licks the honey from the flower into its mouth, which is of considerable size, and thence transmits it to the stomach. All the honey which we see in combs is a vegetable product. After being swallowed by the bees, it is disgorged into their cells; but its scanty quantities in the natural state prevent us from ascertaining what change is undergone in the stomach. Until very lately, it was believed that the bees also swallowed the wax, and disgorged it to construct the cells; and, when so disgorged, that it had the property of indurating, like the substance forming silk, immediately on exposure to the air; and that the mandibles were used in moulding the parts to their proper size and thickness. It is now proved, that wax is made out of honey, which is swallowed by the bees indeed, but there is great reason to believe that it then transudes through the membranes connecting the rings of the body in the form of wax. The females and workers have a sting, of which the males are destitute. This is not a simple sharp-pointed weapon, as apparent to the eye of a superficial observer; it consists of two separate portions, applied longitudinally against each other. The external side of each is provided with several barbs, like those of a dart, which prevents the retraction of the sting from the wound it has inflicted, until the purpose of its penetration, the discharge of poison, be fulfilled. These barbs, it is said, may be elevated and depressed at the will of the animal. Having satisfied its vengeance, the sting is withdrawn; but if the bee is suddenly forced away, the barbs remain elevated, and retain the sting in the wound. The extraordinary pain attending so small a puncture, arises from a liquid, which is genuine poison, flowing into the wound from an oval bag, or reservoir, in the body of the animal, connected with the sting; and its virulence is such, as even to occasion death, if the stings be numerous. In experiments where a small portion of the poison was introduced into a slight puncture with the point of a pin, acute pain followed; and, on laying the smallest quantity on the tongue, a sweetish taste first was sensible, which became burning and acrid, and continued so several hours. The effect of the poison is various on different people; in some, a single sting occasions violent swelling and inflammation; others suffer little inconvenience from it. If the sting be left in the wound, its vital powers will force it still deeper; therefore it is cautiously to be extracted, and the part sucked and washed with vinegar, or some liquid

fit to allay inflammation, that being probably the only effectual mode of cure. We cannot readily ascertain the real use of the sting to bees. It is vain to affirm, that it is an organ of defence against enemies; that the treasures of a hive are particularly exposed to depredation, and require great protection. Many other insects, in similar circumstances, have no defensive weapon; many possess it which we can hardly say have any thing to guard; and some, exposed to numerous accidents, are entirely unprovided with the means of averting them. The sole purposes to which we see the sting applied, independent of the resistance of injury, are massacring the drones of the hive; and by queens, to effect their mutual destruction. Queens are more pacific than the common bees, and less inclined to sting the person that handles them.

The three kinds of bees inhabiting a hive are all of different size and appearance, and may easily be recognised. The common bees and males are familiar to every one; the latter being much larger, and of duller flight. But the queen resembles neither in structure; she is about eight lines and a half in length, while the males are seven, and the workers six. Her abdomen is greatly longer in proportion, and increases much when filled with eggs; her wings are so short as scarcely to reach past the third ring, and her colour tends to a deeper yellow. Queens, and also males, are occasionally seen of smaller size than usual; which naturalists have supposed is owing to accidental circumstances. It is not yet known, however, whether all the bees preserved in hives, in different countries, are exactly of the same species; or, whether there are varieties preserving their peculiar characteristics of size and colour.

Long ago it was ascertained, that the welfare of the queen is indispensable to the welfare of the hive, and that any accident befalling her is fatal to the whole colony. As she is the parent of the hive, it is from her alone that a complete swarm, composed of queens, drones, and workers, can proceed; and without all these different members of the community, it cannot either lay up stores, or be preserved in existence. That bees are propagated by means of eggs, which are hatched into worms, could not be unknown from times of the most remote antiquity; but no point in the natural history of animals has been more keenly contested, than their precise mode of generation. It was concluded, from finding males and females together in the same hive, that their sexual union gave birth to the young; yet no one had beheld their concurrence. Those provided with the means best adapted for observation, could only assert, that something like an indistinct and transient junction had taken place before them. Others, again, with all the assiduity, care, and attention they were able to command, could see nothing of the kind; and thence inferred, that the queen was a real hermaphrodite, which in itself possessed the generative powers of both sexes combined. A third class, where we are surprised the name of Swammerdam should appear, ascribed the impregnation of the queen to a certain *aura* emanating from the bodies of the males, which must necessarily be numerous, in order that it may have sufficient power; and a few observers conceived, that external fecundation of the eggs took place after being deposited in the cell, in the same way as the generation of frogs and fishes is effected. But, on the other hand, young were found in hives provided with queens, though entirely destitute of males. They were seen in spring

long before males begin to exist, and in winter after the whole are destroyed; and an experiment by Hattorf evinced the aversion of queens to drones, rather than an affection for them. He took two virgin queens from their cells, and confined each, along with two drones taken from the same hive, under a glass vessel. One of the drones having approached a queen, was seized by her, and killed on the spot; and the other did exactly the like with one of her companions; the two remaining drones escaped. This experiment, on frequent repetition, presented similar results; and the variety of devices to ascertain the fact were attended with consequences which served still more and more to perplex the observer. At length, however, the truth seems to be disclosed, and we shall briefly advert to the methods adopted for the purpose of discovering it.

M. Huber of Geneva, one of the most intelligent authors who have written on this subject, finding the experiments of all former naturalists unsatisfactory, removed the whole reigning females from a number of hives, and substituted for each a queen taken at the moment she came to maturity. He then divided the hives into two classes; and having removed all the drones from those of the first class, he adapted a glass tube to the entrance, so narrow that no drone could pass, but large enough to admit common bees. The whole drones were allowed to remain in the hives of the second class, and more were even introduced. A glass tube, also, too small for their exit, though of sufficient capacity for common bees, was likewise adapted to the entrance of the hives. This experiment was carefully made; and, to the author's great surprise, all the queens remained sterile; thus proving, that a female confined to her hive would continue barren while amidst a seraglio of males.

The result of successive experiments, diversified in every possible manner, and made with much skill and indefatigable labour, proved, that the generation of bees is effected by the union of the sexes, as in most other species of insects, and the larger terrestrial animals. But it is never in the interior of the hive that it takes place. The queen, to accomplish it, must issue forth from her dwelling—the only occasion, except one, on which she leaves it; and although her junction with the drone has not yet been witnessed by human eyes, it is supposed to happen high in the air. In illustrating the generation of bees, the author whom we have already named concluded, that if queens were obliged to go out for impregnation, it would be at the warmest time of the day, as the males then leave the hive. On the 29th of June, a hive, containing a virgin queen five days old, was made the subject of observation. The sun had shone from his rising; the air was very warm; and, at eleven in the forenoon, the males began to leave the neighbouring hives. The entrance of the one containing the queen was then enlarged, and the bees entering and departing narrowly observed. The males appeared, and immediately took flight; and soon afterwards the young queen came to the entrance. Before quitting the board, she traversed it, and brushed her belly with her hind legs, during which she received no attention either from the males or workers. Taking flight, she again approached the hive, as if to examine the place of her departure, that she might recognise it. Next describing circles ten or twelve feet above the surface of the earth, she rapidly rose in the air, and was soon out of sight. The observer and an assistant hastened to contract the entrance of the hive, and in seven minutes the young

queen returned. No external marks of fecundation being visible, she was allowed to enter the hive. In a quarter of an hour she came to the entrance, and brushing herself as before, took flight. Returning to examine the hive, she departed, rising so high that the observers soon lost sight of her. Twenty-seven minutes elapsed before her second excursion terminated; but now she was in a very different condition from that in which she appeared after the first; for she exhibited the most unequivocal evidence of sexual union, by bringing along with her the genital organs of the male by which she had been impregnated.—And here a wonderful deviation from the ordinary laws of nature ensues; the male loses his organs in copulation, and thus sacrifices his own life in perpetuating his race. In two days the belly of the queen was swollen; and, on investigation, she proved to have laid nearly an hundred eggs in the workers' cells. For some reason, which is unknown to us, the sexual union cannot be accomplished in the hive; and the object of the queen's departure being once fulfilled, she never again leaves it unless to conduct a swarm.

Forty-six hours after impregnation the queen begins laying eggs, which will become workers; and, provided impregnation takes place within the first twenty days of her existence, thousands are produced uninterruptedly during the succeeding eleven months. Then she commences laying eggs which will be drones. But should matters be otherwise arranged; should her impregnation, either from constraint or accident, be delayed more than twenty days beyond her own complete metamorphosis, a singular alteration takes place. She begins laying within forty-six hours of its occurrence, but no eggs excepting those from which drones proceed; nor will she lay any other kind during her whole life. A nice and difficult problem thence arises, which analogy does not aid us to solve. How is the order of nature so completely inverted by retarded impregnation? The eggs producing males require, in the natural state, eleven months to attain maturity; but, under the effects of this accidental occurrence, they reach perfection in forty-six hours. Those eggs which should have preceded them, during eleven months, in many thousands, totally disappear, and from no other sensible cause. Some vitiation has ensued, which, while it destroys the vitality of which the workers' eggs are susceptible, operates such a change, as to bring those of the males eleven months earlier to maturity. On reflecting that a simple copulation is sufficient to impregnate all the eggs which a queen will lay in two years, or, perhaps, the whole that she will lay during her life, the question becomes still more embarrassing. Without being aware of the cause of such peculiarities, some observers have maintained, that there were certain species of queens, from which no description of bees, excepting drones, would be generated; which they justly determined was extremely injurious to their respective colonies.

The laying of a queen is retarded, or altogether interrupted, by cold; and one impregnated in the end of October has been known to retain her eggs four months and a half, owing to the intervention of winter. This queen, during March and April, laid above 3000 eggs, producing males only; and so very prolific are these insects, that a single queen may be the mother of 12,600 bees, or more, in the space of two months, which is laying at the rate of 200 eggs daily. The queen before depositing an egg, examines whether the cell is clean and

fit to receive it, and also suitable to its future state; for queens, males, and workers, have cells peculiarly adapted to their kind, and the queen, by anticipation, seems aware which of these will proceed from the egg she deposits. Those producing workers are deposited in common horizontal cells; but the cells containing the eggs which will be transformed into queens are large and rudely constructed, with a great quantity of wax, and hang perpendicularly in the hive. When the egg is laid, the bees supply the cell with the pollen of flowers, which serves to feed the young worm coming from it.

The eggs of all the three kinds of bees are hatched in three days; a fact apparently of trifling import, but which it is essential for the cultivator to learn. A worker then remains five days in the vermicular state; a male six and a half; and a queen five. The workers' worm occupies thirty-six hours in spinning its silken envelope or cocoon; in three days it changes to a nymph; and only on the twentieth day of its existence does it become a complete or perfect winged animal. The drones are still longer of attaining their last metamorphosis, which succeeds in twenty-four days after the egg has been laid. But the queen comes to perfection in sixteen days.

Food is carried by the bees to the worms as they require it: but when ready to transform to a nymph, they are aware that it is no longer necessary; on the contrary, the mouth of the cell is sealed with a covering of wax formed of concentric circles from the edge, convex if including males, and flat if including workers. The same cell may successively bring different workers to maturity: after one has left it, the bees clean the inside, and the mother again lays there; but the cells containing eggs which become queens are used no more than once. When the perfect insect escapes, the cell is usually destroyed.

While treating of the origin and imperfect state of bees, we cannot omit observing, that although, generally speaking, the queen is the parent of the whole, yet there are some workers, (at least some bees so much resembling workers, that there is no perceptible difference,) which lay eggs. Their ovaries are smaller, more fragile, and composed of fewer oviducts than those of queens; and the eggs, like the eggs of queens whose fecundation has been retarded, produce male bees only, and neither queens nor workers. This singular fact, added to another not less so, on which we shall immediately make a few remarks, strongly tends to establish, that all working bees are originally of the female sex; and that in the ordinary case their ovaries are vitiated, and become unfit for laying any eggs except those transforming to males.

M. Schirach, an eminent naturalist, discovered, that in certain circumstances the animal destined to become a worker could actually be converted into a queen; and that this conversion was in the power of the bees, by means of a particular mode of treatment bestowed on the worm while in an early stage. He thence concluded, that every queen is originally a worker, which, without the particular treatment administered, would have remained a worker, but having undergone this treatment, it is converted to a queen; and that the bees, to attain the conversion, selected the worm when three days old. Nevertheless it is indubitable, that specific eggs are laid in royal cells and hatched into queens, which, according to the most credible and satisfactory experi-

ments, never would have produced workers. It is surely to avoid the fatal consequences which would attend twenty or thirty thousand animals on the loss of a single life, that they have been endowed with such uncommon prerogatives.

Immediately on the loss or removal of a queen, the whole hive is a scene of tumult and disorder: the bees seem to anticipate their own destruction, by the precaution they take to guard against it. Should there be neither eggs nor brood in the combs, they will infallibly perish; their instinctive faculties are lost, they have no object for which their labours are united, they cease to collect honey and prepare wax, and in a short time they disappear and die. But if there be brood in the combs, the industry of the bees continues unabated; for by the proceeding which they follow, they know that their loss will be repaired. Having selected a worm three days old or less, they sacrifice three of the contiguous cells, that the cell of the worm may be formed into one adapted to breed a queen. They next supply it with the necessary food, which is not the common farina, pollen, or bee-bread, on which the young of workers feed, but a peculiar kind of paste or jelly, of a pungent taste, which is reserved for queens alone. A cylindrical enclosure is raised around the worm, whereby its cell becomes a perfect tube with its original rhomboidal bottom; for that part remains untouched. Were it injured, the fabric of the other three cells on the opposite side of the comb would be deranged, which would be a needless waste. The cell is still horizontal like the rest in the combs, and thus remains during the first three days of the existence of the worm; but the bees in prosecuting its enlargement, alter its direction, and form it to hang perpendicularly, as all those cells do which have been inhabited by queens. In performing this essential part of the operation, they do not scruple to destroy the worms surrounding the tube, and use the wax of their cells in constructing the new part, which they apply at right angles to the first, and work downwards. The cell is then of a pyramidal figure, usually near the edges of the combs; it insensibly decreases from the base, and is closed at the top when the included worm is ready to undergo its transformation to a nymph. When reaching maturity, the seal is broken, and a queen comes forth qualified to fulfil every indispensable function on which the preservation of so many thousand lives depends. Working bees have therefore the power of effecting the metamorphosis of one of their own species, to avert the effects of a loss which would prove the utter ruin of the whole colony.

A question extremely abstruse, and difficult in the physiology of animated existence, here presents itself. Whence does it happen that bees are susceptible of so great a change? and that an animal naturally sterile, and possessing certain definite habits and properties, which it is death to interrupt or alter, should be converted into a creature of different figure, uncommon fertility, and endowed with instincts bearing little or no resemblance in the one state compared with the other? Some naturalists have endeavoured to seek the cause of this singular fact in the food with which the larva is supplied in its cell. That food, they affirm, is not the same as what is given to the young of common bees, as may easily be discovered by its taste and consistency. It possesses a certain quality which affects the organization of the insect, it enlarges the size, expands the ovaries, and operates the whole alteration. By similar

reasoning they endeavour to explain the cause of that fertility, which is at times, though rarely, seen in workers. These workers they suppose to have inhabited cells in the immediate vicinity of royal cells, during the earlier part of their own existence. Particles of the food appropriated for queens having accidentally fallen among what was destined for the common worms, produces a partial change in particular organs; though under its influence the ovaries are but imperfectly expanded, and also labour under a vicious conformation, which unfits them from propagating any eggs excepting those transforming to drones. We cannot subscribe to these doctrines, which proceed from the most intelligent naturalists of the present age, because they are unsupported by experiment. The subject is to us still wrapt in mystery; nor is it to be aided by any fact with which we are acquainted in the generation of animals. Perhaps it affords some reason for believing, that the germs of all animals are of one sex only, it may be of no sex, but possessing organs susceptible, in certain cases, of a different kind of evolution. We are indebted to Schirach for the original discovery of this property enjoyed by bees, which has subsequently been confirmed by other observers.

These being the imperfect stages which bees undergo, and their ultimate transformation being completed, three different kinds, females, males, and workers, whose offices, nature, and properties, are also different from those of each other, inhabit the same swarm. In common with other insects, they are of a lighter colour at the moment of issuing from the cells, and totally covered with hair, which is less abundant on the queen. The quantity of it seems to diminish with their age: it is not known how long they survive, but most probably above one or two years, or considerably more. The queens and drones of smaller size, sometimes found in hives, are regarded as aberrations from the general race. Their nature has not hitherto been fully illustrated; but naturalists have ascribed this diminution to the eggs producing them having accidentally been laid in wrong cells: that their organs are there cramped and confined, and prevented from attaining their due expansion from the smallness of the cell. At the same time, though the eggs producing workers are laid in cells of greater than ordinary size, the reverse does not ensue, and the body is still restrained to its natural dimensions. Schirach obscurely hints his opinion, that the greater length of the queen is owing to the greater length of her cell.

We shall next explain the peculiar office and functions of each species of bees, the queens, drones, and workers, in their perfect state, and shew the mutual relation that must subsist among them, in order to ensure the welfare of the community. In the history of other insects nothing more is taken into consideration than a general view of the structure, habits, and perpetuation of the race. But in treating of bees, we have not only to enter on the origin of each variety in a hive, to follow it through its successive stages until gaining perfection; to examine that internal œconomy which the instinct of many thousand individuals regulates; but we have to shew the cultivator, who designs converting their labours to advantage, how their nature operates separately as well as combined.

The sole functions of the queen bee are to perpetuate her species; but single and unassisted by the workers, herself and her offspring would perish. Her fecundity

is surprizing. Swammerdam affirms, that she contains 50,000 eggs; and some authors advance, that she may be the mother of 100,000 bees in one season. In addition to the peculiarities exhibited in her propagating young, she is marked by others of the most conspicuous description. She is watched and attended to; and, to judge from appearances, sheltered and respected by the workers. Groups of them constantly encircle her; they supply her with honey, brush and lick her limbs; whenever she moves, they recede before her; and, according to the united sentiments of all who have studied the nature of bees, pay her what would be called real homage, could we allow them the prerogative of understanding. She is an object of the greatest attachment; her presence inspires them with new instincts, and animates them to labour: the permanent existence of a queen, in short, is the only security of the workers. Excepting when she leaves the hive for fecundation, they cluster around her; and hence some persons have endeavoured to impose on the credulous, as having a command or power over bees. It is true that such persons could make a whole swarm follow them from place to place without injury to themselves or the spectator; but the sole secret consisted in their having obtained possession of the queen. The natives of foreign countries are acquainted with this attachment of the workers to their queen, which some years since was exhibited in Britain under mysterious disguise, as Labat, long ago, relates in his Travels. He received a visit from a man who called himself *master of the bees*. "It is certain they followed him as sheep do their shepherd, and even more closely. His cap in particular was covered in such a manner, that it exactly resembled those swarms which, in endeavouring to settle, fix on some branch of a tree. Being desired to take it off, he did so, whereupon the bees settled on his shoulders, his head and his hands, without stinging him or those in the vicinity. All followed him when he retired; for besides those which he carried about, they attended him in legions." People accustomed to handle bees with address, can easily seize the queen, and then, as during swarming, little is to be apprehended from the bees attempting to sting; they are too much occupied in regarding their queen.

Though the queen lays several eggs, which will be successively transformed into queens, only one in its perfect state can exist in a swarm: a plurality seems equally adverse to the intention of Nature as a total defect. Hence it follows, that of two coming at the same time into existence, one must die for the welfare of the community. But the charge of accomplishing the destruction of the victim is not confided to the common bees; the queens themselves are entrusted with it. Were it otherwise ordained, dangerous consequences might be the result; for while one group of bees destroyed the first of two queens, another might massacre the second, and the hive being thus deprived of both, would perish. Nature has therefore inspired queens with the most deadly animosity, and the most insatiable thirst for each other's life, which nothing but actual death can appease.

The same intelligent naturalist, M. Huber, to whose authority we frequently recur, gives an interesting account of the combats of queens, part of which we shall abbreviate. In one of his hives fittest for observation, two young queens left their cells almost at the same moment. Whenever they observed each other, they

rushed together apparently with great fury, and came into such a position that the antennæ were mutually seized by their fangs. The head, breast, and belly of the one, were opposed to the head, breast, and belly of the other. The extremity of their bodies had only to be curved, that they might be reciprocally pierced with the stings, and both fall dead together. But nature has not decreed that the two combatants should perish in the duel: when in the position now described, they separate, and retreat with the utmost precipitation; and when these rivals felt their extremities about to meet, they disengaged themselves, and each fled away. A few minutes after separating, however, their mutual terror ceased, and they again began to seek each other. Immediately on coming in sight, they again rushed together, seized one another, and resumed exactly their former position. The result of this rencounter was the same: when their bellies approached, they hastily disengaged themselves, and precipitately retreated. During all this time the workers were in great agitation; and the tumult seemed to increase when the adversaries separated. Twice they interrupted the flight of the queens, seized their limbs, and restrained them prisoners about a minute. At last, that queen which was either the strongest or the most enraged, darted on her rival at a moment when unperceived, and with her fangs took hold of the origin of her wing, then rising above her, she curved her own body, and inflicted a mortal wound. She withdrew her sting, and likewise quitted the wing she had seized: the vanquished queen fell down; dragged herself languidly along; and her strength declining, she soon expired. Another experiment, equally interesting, on the mutual antipathy of queens, elucidates the instinct of the common bees, and seems to prove that they are aware of the necessity that such combats should have a fatal issue. M. Huber having painted the thorax of a queen, on purpose that she might be recognised, introduced her into a hive already provided with the natural queen. A circle of bees quickly formed around the stranger, but not to caress or receive her with that grateful homage which a queen is wont to experience; on the contrary, they insensibly accumulated to such a degree, and encompassed her so closely, that scarce a minute elapsed before she lost her liberty, and became a prisoner. By a remarkable concurrence, the workers at the same time collected around the reigning queen, and restrained all her motions: she was instantly confined like the stranger. But as if the bees anticipated the combat in which these queens were about to engage, and were impatient to witness its issue, they retained them prisoners only when preparing to withdraw from each other; and if one less restrained seemed desirous of approaching her rival, all the bees clustering together gave way, to allow her full liberty for the attack: then if the queens testified a disposition to fly, they returned to enclose them. These facts form a singular anomaly in the history of bees. That they take a decided part on the occurrence of such combats, is indubitable; but if they mean to accelerate them, how shall we account for the uncommon care and attention, on every other occasion, bestowed on their queen, being now forgotten, and for their opposing her preparations to avoid impending danger? The cluster of bees that here surrounded the reigning queen having permitted her some freedom, she appeared to advance towards that part of the comb on which her rival stood. All the bees receded before her: the multitude of

workers between the adversaries gradually dispersed, until only two remained: these also removed, and allowed the queens to come in sight. At this moment the reigning queen rushed on the stranger, and fixing her against the comb, mortally pierced her body with her sting.

The mutual antipathy manifested by queens, is not limited to their perfect state, for it extends to nymphs yet in the cells. The future existence of a rival, which may dispute her place in the hive, seems to excite apprehension in a queen already come to maturity. The oldest queen in a hive containing five or six royal cells, having undergone her ultimate metamorphosis, hastened, within ten minutes of escaping from her confinement, to visit the cells of the rest still close. She furiously attacked that nearest to her, and, by dint of labour, succeeded in opening the top: then she began tearing the silk of the cocoon; but her efforts being probably inadequate to her purpose, she sought the other end of the cell, where she effected a larger aperture. When of sufficient size, she endeavoured to introduce her belly; and after many exertions, succeeded in giving her approaching rival a deadly wound. When she left the cell, the bees, which had hitherto been spectators of her labour, began to enlarge the opening, and drew forth the body of a queen scarcely come from the nymphine state. Meanwhile the victorious young queen attacked another royal cell; but did not endeavour to introduce her sting: it contained only a nymph, and not a perfect queen as the former did. Hence it has been conjectured, that the nymphs of queens inspire less animosity: still they do not escape destruction, for whenever a royal cell is opened before its proper time, the workers extract the contents in whatever form they appear, whether worm, nymph, or queen. Accordingly when the young queen had here abandoned the second cell, the opening which she had made was enlarged by the bees, and they extracted the included nymph. Nymphs of other hives, introduced into one where there is a queen, are equally the subject of animosity. But in this general work of destruction, there is a fact, in the natural history of bees in their earlier stages, elucidated, which we should otherwise find it difficult to explain. The larvæ of the whole three species are endowed with a property widely diffused among insects, that of spinning silk. Each, as we have before observed, spins itself a web or cocoon, in which it resides a certain time inactive, previous to transformation to the perfect state. The larvæ of workers and males, spin complete cocoons close at both ends; the cocoons of queens are imperfect, covering only the head, thorax, and first ring of the abdomen. Nor can the larva do otherwise; the particular form and position of the cell force it to leave the ends of the cocoon open, while in the natural state; but if removed from it, and situated in the same circumstances as the larvæ of males and workers, a complete cocoon is fabricated, in which the animal is fully enveloped. But the purpose of the open cocoon is only now to be discovered; it is, that the inclosed nymph may be exposed, without resistance, to the deadly jealousy of its rivals. Were it close, the sting of the queen, which seems never to be used excepting to destroy her own species, might be entangled in the silk, by which she herself might become the sacrifice, and occasion the loss of the whole hive.

Though only a single female can exist in a swarm, several hundreds, and sometimes thousands, of drones

inhabit it. They originate towards the summer season, eleven months after the queen has commenced laying those eggs that become workers, that is, when the propagation of the colony takes place. The sole office of the drones, so far as has yet been discovered, is to fecundate the queen; for we can scarcely admit, as several authors have done, that their heat and custom of crowding on the combs is instrumental in hatching the young brood. Concerning the structure of the genital organs, which are extremely complicated, we shall refer to the works of Swammerdam, Reaumur, and Huber, who have expatiated on it at great length. Drones want a sting; and there is a difference in the conformation of several other parts of the body, as the trunk and antennæ, from those of females and workers. They do not collect honey, but consume it; and instead of entering the cells, as the females and workers do, for repose, they cluster together on the combs. If the sole office of drones be to fecundate the queen, we cannot well account for their numbers. Why should thousands dwell in a hive a burden on the community, when one is enough to perpetuate their race, and when only a single impregnation is required? Naturalists, who have ascribed the fecundation of the queen bee to a certain *aura* emanating from the males, judged it essential that they should be in numbers, that the *aura* might have sufficient power or intensity. Those observers, again, who have demonstrated, that impregnation is operated without the hive, deem it necessary that the drones should be numerous, otherwise the queen would have little chance of meeting any one in her course through the air; and others, even the most acute persons, who allowed themselves to believe, that here the solicitation was on the part of the female, thought that this redundancy of males was given, in order that she might make her choice. These reasons are to us alike unsatisfactory: the first, from its being utterly adverse to the laws which regulate the preservation of animals; the second, from resting on no surer basis than on simple conjecture, still unsanctioned by evidence; and the third, from being a conclusion on facts which never happen. Nevertheless it is unquestionable, that a hive, deprived of drones, will produce no young, though we cannot form an idea of the precise number necessary for the ends of generation.

After a particular period of the year, when the queen has been impregnated, and when the masculine properties of the drones are no longer of any use, they are mercilessly destroyed by those very workers which once watched so carefully over their origin. This is a fact well known, and has given birth to various hypothesis. In Britain, as in other countries, the period of the massacre probably depends on the advancement of the season, and always happens during the autumn months. The drones then flying from destruction, are seen on the flowers, occupying the panes of our windows, or wandering about from hive to hive, which they no sooner enter than death awaits them. This incident occurs sooner on the continent, where the seasons are earlier, compared with ours; and we shall cite the substance of some observations by a Swiss naturalist, by which it is materially illustrated. "It is usually in the months of July and August that the bees free themselves of the males. They are at that time drove away and pursued to the inmost parts of the hive, where they collect in numbers: and as many are then found dead on the ground, it was to be concluded that; after being expell-

ed the hive, they are stung to death by the bees. Yet on the surface of the comb, the sting is never observed to be used against them; the bees seem satisfied with pursuing and chasing them away. To ascertain the truth, we thought of getting the support of the hive made of glass, and of placing ourselves below, to discover what passed in the scene of action. A glass table was therefore constructed, on which six hives containing swarms of the same year were put, and lying under it, we endeavoured to see in what manner the drones were destroyed. Our contrivance succeeded to admiration: on the 4th of July, we saw the workers actually massacre the males in the whole six swarms, at the same hour, and with the same peculiarities. The glass table was covered with bees full of animation, which flew on the drones as they came from the bottom of the hives, seized them by the antennæ, the wings, and the limbs; and, after having dragged them about, or, so to speak, after quartering them, they killed the unfortunate victims by repeated stings, directed between the rings of the belly. The moment that the formidable weapon, with which the workers are armed, touched them, was the last of their existence; they stretched their wings and expired. At the same time, as if the workers did not consider them so completely dead as they appeared to us, they struck the sting so deep that it could scarcely be withdrawn. Next day having resumed our position, we witnessed new scenes of carnage: during three hours the bees furiously destroyed their males. On the preceding evening they had massacred all their own; but now they attacked those which, driven from the neighbouring hives, had taken refuge amongst them. We saw them also tear some remaining nymphs from the combs: they greedily sucked the whole fluid from the abdomen, and then carried them away. The following days no drones remained in the hives."

The cause of this cruel extirpation of so great a portion of the community, is very far from being evident. It is not enough to say, that it is from the drones being no longer of any use in propagating the species: or that their numbers would be a burden on the rest, seeing they are altogether inefficient. Conclusions deduced from either of these reasons, are not to be admitted in our present state of knowledge respecting the natural history of bees. Probably, however, our attention should be directed to the consequences of the drones having fulfilled the purposes of generation; for they are never destroyed in hives wanting queens, nor in hives where queens lay eggs producing males only. In both situations they are tolerated and fed, and may be seen living in perfect security throughout the winter. The massacre happens in those hives alone possessing queens completely fertile; but never until the season of swarming has elapsed.

In considering the nature of the individual species of bees inhabiting a hive, an acquaintance with which, we repeat, is indispensable before converting their labours to use, we have to notice some of the peculiarities exhibited by workers. It is to this great class that the welfare of a hive properly belongs: without their incessant aid, the males, females, and even the brood itself would quickly perish; and if the presence of a queen be essential to their safety, they are no less requisite for her preservation.

Certain facts, we have already remarked, tend to establish, that all workers are originally females; and in most, perhaps in every hive, some are found laying eggs,

which will be future drones. But here viewing them as a large class of the community, consisting of twenty, thirty, nay forty thousand individuals, we behold them employed in various purposes, extremely diversified, for the general good. They are charged with cleaning and preparing the cells appropriated for the embryos of their own kind, of the queens, and the males: they collect the honey, obtain wax, and build the combs: likewise, they gather a particular substance, (resinous, as is supposed) with which all the crevices of the hive are closed, and its inside covered. After the queen has deposited her eggs, the workers supply the food adapted for the worms of each species, and regulate the proportions, so as to serve until the last metamorphosis is undergone: and they seal every cell with a covering different, according to the different worm included, at the proper and appointed time. Nor are these the limits of their occupations; while some guard the queen, construct the combs, and watch over the necessities of the young, others keep constant watch, day and night, at the entrance of the hive: if a stranger bee, a wasp, or noxious insect appears, it is instantly repelled or destroyed: even should a queen, which, on usual occasions, is treated with such unequivocal marks of regard, be introduced to the hive of any swarm but her own, the workers immediately seize and restrain her, and, without being wounded with their stings, the confinement she suffers is such, that she sometimes dies of absolute suffocation.

All the operative parts of the œconomy of the hive are entrusted to the workers; and as the collection of honey and combs which they construct are the substances converted to our use, and indeed is the main purpose of our cultivating them in numbers, it is proper that we should elucidate the manner in which this is effected. Honey is a vegetable secretion, which appears at different seasons of the year, especially when flowers in general blow. We can readily understand how it is stored up by the bees: they lick it with the proboscis from the flowers; it is swallowed; and on their return to the hive, it is disgorged, not from the trunk, but the mouth, into the cells. Only a small portion is collected by each, but the united labours of thousands produce an abundant harvest. Reaumur has calculated, that within an hour 3000 bees have returned from their collections to a hive, whose population did not exceed 18,000; and in six days, Swammerdam, if we rightly understand his expressions, found nearly 4000 cells constructed by a new swarm, consisting of less than 6000 bees. Some of the cells filled with honey are destined for the daily consumption of the bees, and others are sealed up and reserved for times of necessity. Many of the labourers free themselves of their collections before reaching the cells, by bestowing them on their neighbours; the trunks of the latter are seen extended, and they receive the honey with them as it is disgorged.

Honey being a vegetable product, its properties depend entirely on the nature of the plants from which it is collected: one kind is of the finest flavour, delicious to the taste, pure and transparent; another is entirely of a different consistence, dark, greenish, tenacious or bitter; and a third kind has been known to produce deleterious effects, which were almost, if not completely, fatal to human life. Dioscorides, Pliny, and various ancient authors, speak of honey in the East being dangerous in certain years; and Xenophon relates, that when the army of ten thousand approached Trebisonde, the soldiers having partaken copiously of honey found in the neigh-

bourhood, were affected like persons inebriated; several, on whom it had more violent consequences, became furious, and seemed as if in the agonies of death. Though none of them died, all were extremely weak for three days. In recent times, we are told of the pernicious effects of a particular kind of honey collected in America; and plants grow in the Archipelago, the honey of which is said to occasion vomiting. Thus Don Felix Azara informs us, that there is a particular kind of honey collected in Paraguay, called *cabatatu*, which occasions a severe headach, and produces as perfect intoxication as ensues from brandy; while another kind brings on convulsions, attended with the most excruciating pains, which last thirty hours. See HONEY.

Bees are seen laden with a yellowish substance in very considerable quantities, which also is stored up in the hive. This is not wax, as is commonly supposed, but either the pollen of flowers, which is used for feeding their young, or propolis for stopping the crevices of their dwelling. The combs are constructed of wax, which owes its origin to honey: or it may be formed from sugar, the saccharine part of which constitutes one principal ingredient of honey. Naturalists have adopted many conjectures concerning the mode in which it is elaborated by the bees. In general they supposed that the yellowish pellets adhering to their limbs were swallowed, and afterwards disgorged as wax in a state of purity. The process is still obscure, but recent experiments seem to afford reason for believing that it may transude between the scales of the abdomen; and the appearance presented by wax on such places led former observers to affirm, that it was collected there instead of on the limbs. It is established by satisfactory experiments, that, whatever be its issue from the body of the bee, it originates from honey. Mutual relations subsist in their elementary principles, and the one is dependent on the other. Those years unproductive of honey are also unproductive of wax; and we often see swarms which begin their collections with the most promising appearance, still make but little progress, and terminate with acquiring too small a quantity of honey for their future subsistence. In these cases, wax is sparingly provided also. What led to a narrow investigation of the preparation of honey from wax, was a naturalist observing that bees continued carrying quantities of the yellow pellets or pollen into hives quite full of comb, and where there was no room to construct more; and on the other hand, that they enlarged the combs of hives containing only a small portion, and did so without carrying in the pellets at all. Succeeding experiments proved that the pollen which they collect from the antheræ of flowers, is used solely for feeding their young, being the same which, in ordinary description, we call farina, or bee bread; and that they will take it grain by grain in their teeth, to transmit it into the mouths of the larvæ: a remarkable trait of patient industry. In ascertaining the mode by which wax was produced from honey, M. Huber confined a swarm of bees in a straw hive to an apartment, along with a quantity of honey and water necessary for their subsistence. The honey was exhausted in five days, and five combs of the finest snow-white wax were then found suspended from the arch of the hive. Lest this might have been the produce of the farina carried in by the bees when their confinement commenced, all the combs were removed, and the imprisonment of the bees repeated. But the result was the same; they formed other five combs of the finest and whitest wax.

It is the saccharine part of the honey which produces wax; and bees supplied with equal portions of honey, and of sugar reduced to a syrup, produce a greater quantity of wax from the latter. From a pound of refined sugar reduced to a syrup, and clarified with eggs, a swarm of bees produced ten drams and fifty-two grains of wax, darker in colour than what they extract from honey: From a pound of dark brown sugar, they prepared twenty-two drams of very white wax, and the like from the same weight of sugar of the maple. Wax is produced sooner, as well as in greater proportion, from sugar than from honey; and the darker the sugar, the finer is the wax. Repeated observations prove, that the secretion of honey in flowers is powerfully promoted by the electricity of the atmosphere; and bees never labour more actively than during humid sultry weather, and when a storm is approaching. Sometimes the secretion of honey is entirely suspended by the state of the weather, which occasions a total interruption of the labours of the bees; and if this be too long protracted, a populous hive may actually die in the midst of summer. The odour exhaled by the hives, and the size of the bees, are always certain indications whether the flowers contain honey. When numbers of bees return from their excursions with the belly thick and cylindrical, it shews they are gorged with honey; and these are exclusively the workers in wax. The belly of those performing the other functions, always preserves its ovoidal form, and does not sensibly increase in size. Although the flowers be destitute of honey, bees still are able to store up quantities of farina or pollen necessary for feeding their young. Part of it is immediately given to them, and, as is affirmed, what is superfluous is reserved in cells. Sixty-five hives, the whole of which exhibited workers in wax, were examined on the 18th of June, when the country was covered with flowers, and while the bees actively pursued their collections. Those returning to old hives, having no cells to construct, deposited their honey in the combs, or gave to their companions; but those of new swarms converted their honey into wax, and hastened to build combs for the reception of their young. Chill and showery weather interrupted their labours, and the combs received no addition by the construction of new cells. The weather however altered, the chesnut and elm were in flourish, and the thermometer on the first of July rose to 77°: the bees resumed their labours with the utmost activity from that day until the 16th, both in honey and wax. But thenceforward no honey being produced, they collected quantities of pollen only; and the odour of the flowers shewed there was nothing excepting an inconsiderable secretion of honey at intervals, barely sufficient for subsisting the bees. It was found, on examining the sixty-five hives in the end of August, that, after the middle of July, the bees had ceased to work in wax; that they had stored up a great quantity of pollen; that the honey of the old hives was very much diminished, and in the new ones scarce any remained; as what was at first collected had been consumed in the preparation of wax. Thus it appears, that, in the natural state, honey is the source of wax, and the food of bees; that its secretion from flowers is affected by adventitious circumstances; and that its qualities are different in different countries. No elementary principles of wax reside in pollen; this substance is collected solely to feed the young contained in hives, and the perfect bees themselves never live upon it. See **Wax**.

The propolis is another substance collected from plants, which is extremely useful to bees. Besides the purposes of stopping crevices, covering the interior surface of the hive, the sticks supporting the combs, and gluing the hive to the board on which it stands, bees employ it in greater portions at once. Stranger animals of small size entering a hive are immediately stung to death, and then dragged by the bees to the outside: there are few persons who have not seen that a dead fly, or bee laid on their board, is quickly carried away and dropped at a distance: it seems the nature of these insects not to endure any filth or corruption in their habitation. Should a larger animal, such as a snail, make its way into the hive, it does not escape; it is put to death, but the bees are unable to divest themselves of its body. Maraldi relates, that he saw the dead body of a snail totally covered with propolis, and thus prevented from spreading infection in the hive; and Reaumur tells us, that a shell snail having fixed itself on the pane of a glass hive, waiting until the moistness of weather should be an inducement for it to move, the bees encircled the mouth of the shell with so thick a bed of propolis, that the animal, unable to moisten it as it moistens its own gluten, was arrested on the spot. The original source of the propolis is not yet perfectly understood: it is much more tenacious, and attains a greater degree of hardness than wax: those bees that return laden with it, owing to its tenacity, experience considerable difficulty, even with the aid of their companions, in divesting themselves of the load. M. Ducarne observes, "several times I have seen bees occupied in collecting, or rather in tearing away with their teeth, the propolis of old hives which I had exposed to the sun; and this appeared so laborious, and the animals pulled so forcibly, that I thought their heads would have been separated from their bodies."

The structure of the cells, which are exclusively the production of the workers, has excited admiration in every contemplative mind; and it is demonstrable, that their figure is the best adapted for containing the greatest possible quantity in the least possible space. A number of cells united constitute the comb, between twelve and thirteen inches square of which, Reaumur calculated, would contain 9000. The primary object of the cells seems to be for propagating the young; after these have gained maturity, they are cleaned out and filled with honey; but there are cells also destined for this purpose from the beginning. The same cells may be employed for several successive broods, and when the whole have come to perfection, they are appropriated for the winter stores: those at the top of a comb are neatest and best made, as well as of better materials, compared with those at the bottom. In the shape and size of the comb, bees are guided by circumstances; a small cavity is totally filled with equal combs, while in one of greater dimensions there may be some large, and others not one-fourth of the size. By a law of nature, from which they seldom deviate, the foundation of the second comb is laid parallel to that of the first, and the successive combs are generally parallel to each other. Sometimes they are seen at right angles, or apparently misplaced, which probably results from accidents having an influence on the earlier part of their construction. There is usually the distance of four lines between each; and should the comb, in its construction, have taken an oblique direction, it is afterwards brought into a more perpendicular line by the bees, which diminishes the

vacancy intervening. Combs originate in the top or arch of a hive, and are worked downwards; but should the upper part be removed, it is said the bees will work upwards to fill the cavity. In order to shorten the courses which they would necessarily have to make round the surface of large combs, they open various communications through them, and also open passages between their edges and the side of the hive; at least we are not acquainted with any other purposes of such perforations found in them. The cells composing a comb are of three kinds, corresponding to the three species of bees; but there are considerable irregularities in the structure of all: neither do those of the workers invariably exhibit that perfect hexagonal figure which many persons expect to find. It may appear singular how bees can fill horizontal cells quite full of honey, and yet prevent it from escaping. Perhaps it is partly retained by its own viscosity, and from adhesion to the sides of a tube of such small diameter. Each cell is sealed with a flat covering most ingeniously devised: it is Nature, however, that must have done so. A circle is formed around the mouth of the cell, which is gradually diminished by other concentric circles, until the aperture remains a point capable of being closed by a single grain of wax.

Though the hive be amply stored with honey and wax, and the young brood gradually approaching to maturity seems to leave nothing to be desired by the bees, they all of a sudden desert their habitation to go in quest of another. For this incident, which is called *swarming*, there is no ostensible cause, nor do the reasons assigned for it by different observers prove satisfactory in our estimation; for its occurrence is irregular, and its frequency is uncertain. According to common apprehension, swarming ensues from a hive being overstocked with bees, and especially from a young queen seeking a new dwelling. It never takes place, we acknowledge, unless the bees be numerous; but there are so many exceptions, that we cannot say it is from wanting room: and instead of the young queen, it is always the old one that leads out the swarm: nay, should an old queen have conducted a swarm of this year, she will also be found at the head of the first which next year leaves the hive. Each subsequent colony departing is led by a young queen. An old queen never leaves her hive until she has deposited eggs which will become future queens, nor until her principal laying of the eggs producing drones is over; the common bees construct royal cells only, while she lays those eggs which will be transformed to drones; and after this laying terminates, her belly being more slender, she is better able to fly; whereas it is previously so heavy and surcharged with eggs, that she can hardly drag herself along. One chief cause or concomitant of swarming apparently consists in the agitation of the queen. She is suddenly affected, hastily traverses the combs, abandoning that slow and steady progression which she ordinarily exhibits: her agitation is communicated to the bees; they crowd to the outlets of the hive, and the queen escaping first, they hasten to follow her. Commonly the whole take but a short flight, and the queen having alighted, the bees cluster around her. This constitutes the new swarm. With regard to the precursors of swarming, there is no infallible guide: those on which observers are accustomed to rely, the most frequently prove fallacious. The general indications given by Reaumur, a naturalist of the first eminence, who draws his conclusions from facts,

and has fallen into few errors, are, first, the appearance of drones in a hive; for no swarm will proceed from one where there are none; secondly, when the bees are so numerous, that part crowd about the outside of the hive, or lodge on the board in clusters of thousands; and thirdly, which is the least equivocal sign of the day of swarming, when fewer bees than usual go abroad for collection, and return without honey or wax. Most observers also affirm, that in the evening before swarming an uncommon humming or buzzing is heard in the hive, and a distinct sound from the queen, called *tolling* or *calling*. Mr Hunter compares it to a note of a piano forte; and other authors to different tones. This we rather incline to suppose is not an indication of swarming, but a proof that there is a young queen as yet confined in her cell, and that probably the sound proceeds from her. We shall afterwards have occasion to say a few words concerning the power of a queen in emitting sounds, and the wonderful effect which these instantly produce on the whole workers.

In illustrating the concomitants of swarming, we shall again resort to the observations of the naturalist Huber, one of the few investigators of the subject, whose remarks are to be received with implicit credit. After establishing that an old queen conducts swarms, leaving worms or nymphs in the hive, which, in their turn, transform to queens, he availed himself of a favourable season to follow their history in the perfect state.

A young queen being introduced into a hive on the 12th of May, the bees received her well, and she immediately began laying. Twelve royal cells, all situated on the edges of the communications or passages through the combs, were begun on the twentieth, and on the twenty-seventh, ten of them were much, but unequally, enlarged. On the twenty-eighth, previous to which the queen had not ceased laying, her belly was very slender, and she began to exhibit signs of agitation. Her motion soon became more lively, though she still continued examining the cells, as if about to lay: sometimes introducing her belly, but suddenly withdrawing it without having laid; at other times depositing an egg in a different position from what it should naturally have. The queen produced no audible sound in her course, nor was any thing heard different from the ordinary humming of bees. She passed over the workers in her way: at times, on stopping, those meeting her also stopped, and seeming to consider her, advanced briskly, struck her with their antennæ, and mounted on her back; and she proceeded thus carrying some of them above her. The bees no longer inclosed and formed regular circles around the queen, nor did they supply her with honey; but she voluntarily took it from the cells in her way. Those which were first aroused by her motions, followed her, running in the same manner, and in their passage excited others still tranquil on the combs. The path she had traversed was evident after she had left it, by the agitation there created, which never afterwards subsided. The queen had now visited every part of the hive, and occasioned a general agitation: if some places yet remained quiet, the bees in motion arrived, and imparted that which affected them. The queen discontinued depositing her eggs in the cells: she dropped them at random; and the workers ceased to watch over the young. They ran about in every different direction: even those returning from the fields before the agitation reached its height, no sooner entered the hive, than they participated in the same tu-

multuous impulse : they neglected to free themselves of the waxen pellets on their limbs, and ran heedlessly about. At last the whole rushed precipitately to the outlets of the hive, and the queen along with them.

These facts were ascertained with the utmost care, and corroborated by future experiments. On the first of June, all was quiet in a hive at eleven in the forenoon; but at mid-day the queen, from a state of perfect tranquillity, became evidently agitated, and her agitation was insensibly communicated to the workers in every part of their dwelling. In a few minutes they precipitately crowded to the outlets, and, along with the queen, left the hive. After they had settled on the branch of a neighbouring tree, the observer sought for the queen, thinking, if she was removed, that the bees would return to the hive : a fact which actually ensued. Their first care then seemed to consist in seeking their female : they were still in great agitation, which gradually subsided, and in three hours complete tranquillity was restored.

Our limits preclude us from entering at sufficient length on this most interesting part of the natural economy of bees, and we must be content with referring to the works of the two celebrated authors already cited. The latter ascribes the chief inducement of those bees conducted by young queens to swarm, to the agitation by which the queen is animated being imparted to them. He endeavours to trace the source of that agitation to the antipathy mutually entertained by the females, which, extending even to those in an imperfect state, is directed against the nymphs lodged in the cells. No sooner does a young queen herself attain maturity, than she attempts to destroy her rivals : but there is a constant guard of workers preserved over them ; she is repulsed, maltreated, and driven away. If deserting one cell she approaches another, it is to experience the same resistance ; she is actuated by an unconquerable desire to accomplish her object ; she is harassed by the incessant opposition of the bees ; agitation thence ensues, and she resolves on flight. It is here to be observed, that although experiments prove that the agitation of a queen is communicated to the workers, and though, with regard to young queens, such may influence the bees to swarm, the same reasons will not apply to old queens leading forth new colonies, for what we have above described only belongs to young ones. So long as a young queen remains in a virgin state, she meets with little of that conspicuous respect, care, and attention, which is lavished on her when the bees know she is about to become a mother. She is previously treated with great indifference ; and hence arises the resistance she suffers when attempting to destroy the nymphs in their cells, and her consequent agitation. "But the conduct of the bees towards the old queen, destined to conduct the first swarm, is very different. Always accustomed to respect their fertile queens, they do not forget what they owe to her : they allow her the most uncontrolled liberty. She is permitted to approach the royal cells ; and if she even attempts to destroy them, no opposition is offered by the bees. Thus her inclinations are not obstructed ; and we cannot ascribe her flight, as that of the young queens, to the resistance she experiences." These observations greatly increase the difficulty of attempting to account for swarming ; we acknowledge that here we can find no satisfactory explanation. The old queen, it has been supposed, becomes agitated by the presence of so many royal cells,

and at the prospect of the combats in which she has to engage, and she also communicates her agitation to the workers. The agitation of the females excites motion in the workers, which increases their animal heat, and raises the temperature of the hive to such an insupportable degree, that they hasten to leave it. In a populous hive, where the thermometer stood from 92° to 97° in a fine summer day, it rose above 104° during the tumult which preceded swarming.

The extraordinary instinct and precautions so conspicuous in bees, are apparently affected during the period of swarming. We cannot admit, with those observers, who seem more actuated by the love of the marvellous than an exposure of truth, that they are endowed with that prescience which induces them, before their departure, to prepare a place for their reception. On issuing from the hive, bees, so nearly as we can determine, have no object in view ; and they often resort to situations the most unlikely, and evidently unsuitable for their convenience or preservation. After rising in the air, it is commonly some tree that arrests their progress, and the queen frequently alights at the unsheltered extremity of a branch, where the bees that may have formed into various clusters in the vicinity, come to surround her. But we have known them repeatedly swarm on the grass, near the hive they had forsaken, notwithstanding trees were at no great distance.

Bees swarm only during the best weather, and in the finest part of the day. Sometimes all the precursors of swarming, disorder and agitation, have been seen ; but a cloud passed before the sun, and tranquillity was restored.

If a hive swarms oftener than once, the new swarms consist of those bees that have been abroad when the first event took place, added to young ones come from the eggs, laid by the queen before her departure. Each is led out by a young queen, as there are usually several royal cells in a hive : but the bees can prevent the whole queens nearly of an equal age from leaving their cells, though come to maturity : and when they do liberate them, it is according to their age, which they have some secret means of ascertaining ; for the oldest are invariably liberated first.

The young swarm, whether removed from the place where it settles or not, begins to work ; cells are constructed of wax from the honey the bees have carried along with them ; and nature has so arranged it, that the first eggs laid by the queen produce the operative part of the community.

PRACTICAL TREATMENT OF BEES.—We have thus traced the natural history of the honey bee from its origin until attaining perfection, and shown how the various species form one great colony, where labours are carried on for the common good. We have explained also, that, at a certain season, bees desert their habitation in quest of another, which, in a domesticated state, the cultivator is careful to provide ; and we shall now proceed to the practical treatment of bees, and point out how their labours are to be converted to utility, profit, and pleasure.

All the circumstances above related having taken place, the new swarm is lodged in a hive, there to commence the collection of honey, the fabrication of wax, and the perpetuation of the species. Much has been said of the fittest size and figure of a hive, and of the

substance of which it should consist: wood, straw, and ozers, have all been recommended; and round, square, oblong, and hexagonal hives have had their particular partisans. These things, we apprehend, do not merit the importance bestowed upon them; and our reason for saying so is, from having seen the most ample products of honey, under conditions almost diametrically opposite. At one time we have seen large straw hives, of the ordinary fashion in this country, full to the brim of rich honey comb; at other times we have seen them almost empty, without any sensible cause, and where circumstances seemed to favour the reverse. We are thence induced to conclude, that less depends on the shape and capacity of the hive, than on the kind and quantity of the swarm introduced into it, and on the season in which their collections are made. Examples have come under our notice, where a swarm, lodging in the roof of a house, has produced a great quantity of honey in combs only four or five inches broad: another swarm also in the roof of a house we have known to fill combs above eighteen inches in breadth. Exposure to the north or south has not affected the bees: their provision has been equally abundant. And here we may remark, that in all instances that have fallen within the sphere of our observation, the products of swarms, lodged in the roofs of houses, have invariably been abundant. We do not pretend to account for this. Perhaps it may partly result from their labours being performed without any disturbance or interruption; partly from the greater heat preserved in a roof during summer. Heat is the soul of insects: their action and exertion are directly in proportion to the temperature of the atmosphere; and cold is the bane of their existence. It is not unlikely, also, that the same cause promoting the hatching of the brood, contributes to render the colony more numerous: and if their swarming is at all dependant on want of room, large portions of them have not an equal inducement to seek another dwelling. Pallas tells us, that the Russian peasants, in remote parts of the empire, hollow out a part of the trunks of trees, 25 or 30 feet from the surface of the earth, for the purpose of hives; and cover the opening with planks, having small apertures for the bees. At Cazan, Mr Bell saw hives of a similar form, which the inhabitants bound to the trees at the side of a wood, in order to secure them from the bears.

As abundant collections of honey are often made in the common straw hives, we cannot affirm that they are unsuitable for the purpose; but they are attended with the disadvantage of preventing the owner from an early appropriation of the labours of the bees. One convenience, indeed, lies in the facility of construction, which always merits due appreciation in every branch of rural economy; and, also, that the cost is inconsiderable. Though neither the size nor figure of the hive be important, all modern cultivators seem agreed that it should be susceptible of additions. In the ordinary straw hive, the addition is made by raising it on a circular ring or hoop, either of wood or of the same materials; a clumsy and awkward expedient, which commonly leads the bees to waste much of their labour in filling up crevices. Notwithstanding this, it is adopted in Brittany with some little difference, and there called the *Scotch hive*. The hive itself consists of two pieces, each twelve inches wide, and eleven high, made of rolls of straw. The under one is divided from the other; but a communication hole, fifteen or eighteen lines in

diameter, is left for the bees. As they work downwards the under part, which is nothing but one of our common *ceks*, or broad hoops, is next filled.—Pyramidal hives have been made several feet in height, and divided into different stages, or compartments; which the bees, after being lodged in the highest, would successively fill on removal of the floors or stages. Boxes of convenient size and form, placed above each other, have likewise been recommended, and which we should suppose well adapted for enabling the cultivator, at all times, to take the honey with ease. Such boxes are made of well seasoned wood, nine inches long, the same in breadth, and eight inches high; but from what we have said, there is no necessity for a rigid adherence to these dimensions. In the roof there is a communication hole three inches square, on which is placed another box of similar structure; others may be raised above this to an indefinite height; and the bottom of each is open like the mouth of a common hive. When a swarm is lodged in a box, if only two be used, it is immediately to be put over an empty one, as the bees must have more room; and if more than two are used, a new one is successively to be supplied below. The bees, beginning from above, will soon fill the upper box with honey; and it is then to be separated from that beneath it, by drawing through a long thin pliable knife to cut the comb. The communication hole of the lower box must then be covered with a board, and the box separated carried to a distance, where the bees remaining in it may be dislodged, by turning it up and rapping on its sides with a small stick. The proper time to perform this operation is at sunrise.—Collateral boxes have also been suggested, from the belief of their being attended with greater advantages to the bees. The size is nearly the same with that above mentioned. There is a communication hole in the side, and an opening low and wide below in the sides applied to each other, to allow the bees more ready passage. Collateral hoops of twisted straw or wood were long ago invented, by which means the inventor enlarged his hives to an unlimited extent; and these he kept, with great advantage, in a garret near the roof of his house.—Madame Vicat invented a kind of hive, composed of hollow frames of three sides, which are connected together, and can be separately taken out at pleasure. Each frame is made of three pieces of plank, half an inch thick. The two side pieces are eleven inches high, and five and a half broad; the piece connecting them above is seven inches long, and they are ten inches asunder at the bottom. The sides of these open frames are applied to each other, and if one of four be taken away, an empty one can be introduced, or the remaining ones can be closed together.—Somewhat analogous to this is the *leaf* or *book hive*, invented by M. Huber, some of which construction have recently been adopted in Scotland, after the description he gives of it. This consists of twelve hollow frames, twelve inches high, nine or ten in breadth, and fifteen lines in width, as it is intended each shall receive only a single comb. These twelve frames, laterally applied to each other, form the whole hive. All are connected by means of hinges at the back, so that they divide asunder in opening like turning over the leaves of a book. The ten intermediate frames, between the first and twelfth, are hollow; the outside of these two are covered; in them, also, is an entrance for the bees; there should be one in all the rest, to open at pleasure. On first lodging a swarm in one of these hives, a small piece of

comb should be fixed in a division, to guide the direction of those built by the bees, which will be parallel to it; and as each frame contains but a single comb, it is extremely well adapted for observation, and it also admits the removal of that comb without affecting or deranging the rest. The whole contents are exposed to view, the queen is easily found, and whatever should be removed or altered can be selected with great convenience. The inventor conceives, that the book hive has the property of rendering the bees more tractable; for on opening any of the divisions, the bees rather testify fear than anger, by retiring into the cells as if to conceal themselves. This he ascribes to the effect which the sudden introduction of light has on them; for they are less tractable after sun-set and during night than through the day. The divisions must be separated slowly, and care observed to avoid wounding the bees. If they cluster too much on the combs, they must be brushed off with a feather, and breathing on them cautiously guarded against. The air which we expire seems to excite their fury; and it certainly possesses some irritating quality, for if bellows be used the bees are more disposed to escape than to sting. Another advantage attends the leaf hive, which consists in the power of the operator to make the bees work in wax, or, which is the same thing, to construct new combs. All that is here required is to separate those already built so far asunder as to leave an interval in which additional ones may be constructed. Suppose that a swarm be lodged in a leaf hive consisting of six divisions, each containing a comb. If the young queen be as fertile as she ought, the bees will be very active in their labours, and disposed to make great collections in wax. To induce them towards it, an empty frame, or division, should be placed between two others, each containing a comb. From the necessity which nature has imposed on these insects of never leaving more than four lines between their combs, they will soon begin to build a new one in the empty space, which will be parallel to the others. The number of vacancies left may be proportioned to the strength of the swarm, and the goodness of the season; but they should not be forced too much to work in wax.—M. Feburier, the most recent observer on this subject, and who, we believe, is just about to publish a work regarding it in Paris, has recommended a hive to the National Institute of a quadrangular pyramidal figure, with moveable sides. Its principles are said to be founded on those of M. Schirach and Huber; but, as yet, they are not sufficiently detailed to enable us to explain them. If wood be used, it must be extremely well seasoned, and perhaps covered with some thin varnish on the outside, else it is apt to decay. Sir Torbern Bergman ascribes the scarcity of bees in Sweden principally to employing wooden hives.

Those who are anxious to view the various and progressive operations of bees, may gratify themselves, by procuring hives with glass sides. This can hardly be denominated a modern invention, as Pliny records, that a Roman senator had something of the same kind, made of the thinnest and most transparent horn. But those entirely made of glass were not known on the continent before the year 1680, though they were made with panes in England earlier in the same century; and hives made completely of glass are spoken of in 1655. Glass hives ought not to be round, like the common shape, as the bees are concealed among the combs; they should be square boxes, whose sides consist of four panes. Reau-

mur used them so thin as to admit of no more than two combs being constructed, that he might the better witness the procedure of the inhabitants. A pane on each side of Huber's hollow frames exposes both sides of the comb. Such hives must be covered with a wooden box, or an opaque substance, as light disturbs the operations of bees.

Some authors think that there is greater hazard in giving bees too much than too little room to work, when first lodged in a hive, as their animal heat will not be sufficiently confined. However this may be, they ought afterwards to enjoy enough of space; for we are satisfied that many swarms are injured from wanting it.

Nothing is of greater importance than the size of the swarm lodged in a hive. We repeatedly see large swarms succeed, while small ones, especially towards the end of the season, fail. The bees, therefore, in each swarm should be extremely numerous; and we may confidently affirm, that the cultivator will find much of his success depend on the number of workers contained in a single hive. It appears, that bees are discouraged by the smallness of their own numbers; that, when greatly reduced, their instinct is affected, they labour with less activity, they cease to keep guard at the entrance of their hive, and testify more indifference for their own fate and that of their young. Whether the advantage lies in a numerous swarm making greater collections in a shorter time; in augmenting the temperature of the hive; or in the different internal functions having larger classes of workers to perform them, we shall not attempt to decide. We therefore recommend the junction of two or more swarms into one, particularly when the period of collection draws towards a close, and the sacrifice of their supernumerary queens. By this expedient it will be seen, that while each could hardly subsist itself, and lay up provision for winter, they will be enabled to survive during its most rigorous cold; and, if the operation be performed earlier in summer, they will gather ample stores. Practical directions have been given for the exact weight which a good swarm should amount to. Bonner says, a swarm is very good if it weigh four pounds; and Butler maintains, that "the goodness or greatness of a swarm you may most certainly know by the weight: it being a good one that weigheth five pounds; a reasonable good one that weigheth four; and a very good one that weigheth six." But the number of bees in a pound is very far from being ascertained, which must restrain us from pronouncing on the exact weight that should constitute a good swarm. Thorley, whose work on bees participates of many of those absurdities in which most authors on this subject have allowed themselves to indulge, observes, "In October 1743, when putting the bees of a small late swarm into an empty hive, and afterwards upon a table, I took a particular account of their measure, weight, and number: in measure a quart; in weight one pound and a quarter; in number two thousand." And he concludes, that the number of bees in a swarm weighing four or five pounds would be 8000, or upwards; whence a suitable hive for 8000 or 10,000 bees should be equivalent to two pecks and a half, or three pecks, in capacity. The calculations of M. de Reaumur produce a very different result. A very fine swarm which left one of his hives he estimated to consist of 43,000 bees, and weighed eight pounds. Thus there are, according to him, 5376 in a pound of 16 ounces; and Butler, who, in spite of all the extravagancies of his work, certainly

made some accurate observations, estimates the number of bees in a pound at four thousand four hundred and fifty. We suspect, that both he and Reaumur have overrated the number.

The situation and arrangement of the apiary, claim the cultivators attention. Each hive should stand on a wooden sole, or rest, supported on a single wooden post driven into the ground, or on three close together, near the centre of the board, that the enemies of the colony may have difficulty in crawling up from below. It should be fixed securely, so as to escape being overturned by the wind; but the common custom of laying a turf on the top must be avoided, on account of the harbour it affords to noxious insects. Hives should stand far apart; if there are six hives in one portion or division of the apiary, they should not be less than nine or twelve feet asunder. But too great a number never should be situated in the same district. The collections of bees are drawn solely from flowers, and perhaps, in some small measure, from honey dew, which at times appears on leaves, and is said to produce an inferior honey; it is therefore evident, that immense quantities of bees, actively employed, would not be long of exhausting the whole. The number of hives should, therefore, be regulated by the situation of the apiary. A district abounding with flowers and blossoms will admit of more than one where the chief product is grain. An apiary ought to stand in a quiet sheltered place, where the bees may perform their labours totally undisturbed: flowers, particularly those most fruitful in honey, should be copiously disseminated around; and, for the facility of saving swarms, it is better to have low flowering shrubs in the vicinity than lofty trees. Means should be practised to obtain a succession of flowers in successive seasons, that the bees may always have the collection of honey in their power, and without going to a distance. It is not known how far they fly: some think they traverse several miles; others, that their flight hardly exceeds half a league; but the accidents to which they are exposed render it important for provisions to be near at hand. In the low country, mignonette is said to afford the finest honey, and may be kept in blossom a large portion of the year. Bromwich, an intelligent writer, relates, that, in 1779, he planted a great quantity of it before two bee hives, at a considerable distance from any other bees. With such abundant supplies as this afforded them, few ever left his garden. In September he took the honey, and found it exceed, by above a third, what he obtained from any other two of his best hives, where the bees were obliged to fly farther, and equal in fragrance and colour to what is imported from the warmer climates. It is a favourite flower among bees; for we have observed patches of it, in the very centre of the city of Edinburgh, resorted to from hives beyond the suburbs. Bonner affirms, that he has often "seen a hive, by being placed high heath, become ten, twelve, or fifteen pounds heavier in the month of August; whereas, if it had remained in its original early situation, it would probably have become every day lighter after Lammas."

This circumstance leads us to another point which the cultivator has to observe, namely, changing the situation of his apiary as the flowers surrounding it decrease. Those in one district, as we well know, have entirely faded, while those of another are in full blow. Though the practice of transporting hives to fresh pasturage is not so general as it ought to be, probably because they are seldom numerous in the possession of individuals, it is not unknown in Scotland; and persons

in the vicinity of Edinburgh yearly send their whole stock to the Highlands, for the purpose of gathering honey. In France it is done either by land or water. M. Reaumur mentions the custom of a M. Protaut, who cultivated bees on an extensive scale, and seems to have kept between 500 and 600 hives for a manufactory of wax. These he sent twenty miles from their ordinary station, and, if the place appropriated for them was not productive of food, they were transported still farther. Each hive was put on a coarse cloth, the corners and edges of which were turned up, and secured by binding them round with packthread. Those containing small quantities of comb were kept in the usual position; but those full of comb were reversed, in order to secure the comb. They were then disposed in tiers, two and two, throughout the whole length of carts made on purpose, from 30 to 48 being carried in each cart. The carts travelled slowly over the smoothest road when the journey was long: if the hives were slenderly stored, they sometimes halted near fertile fields, and the bees were allowed to go abroad to feed; having returned at night to their dwelling, the journey was resumed. The Egyptians also transport their bees on a large scale on the river Nile. The inhabitants of Lower Egypt collect the hives belonging to different villages, and pile them up in pyramids in boats prepared to receive them. These boats slowly ascend the river, as in Higher Egypt the flowers are earlier in bloom; and they stop on the way, to allow the bees to fly about and make ample collections on the banks. Three months are occupied in the voyage and return, when each hive is delivered to its proprietor, whose name, mark, or number, has been affixed to it. The modern Greeks, inhabiting the coast of Asia Minor, convey their hives also in boats from shore to shore, in order to reach newer and more abundant pasturages than what they leave. In one of these voyages we are told, that a hive being accidentally overturned, the enraged bees so keenly attacked the seamen, that they were glad to leap overboard and swim to the shore, which fortunately was not distant. The extent of this practice justifies our recommending it as one effectual method of increasing the quantities of honey. The hives must be transported on a spring cart, which, if well hung, an essential quality, ought to travel expeditiously through the night; and they should also be kept cool. Small holes, for the admission of fresh air, should be made in the bottom and sides of the hive; but the operator need not dread the consequences of keeping his bees one or two days in total confinement. In changing the situation of the apiary, certain conveniences must be sacrificed; but when it remains stationary, its proper position is in a field or garden, where it is sheltered from the winds, and protected from the access of cattle and the curiosity of mankind, by a railing. Flowers and shrubs ought to be in the immediate vicinity, and trees at a distance. It should not be encompassed by high walls, for the bees, from either being heavily laden, or fatigued with their labours, or affected by the sudden chill of evening, predominant in our own climates, are unable to surmount it: and there are the same reasons against its being encircled by a thicket. A southern exposure is not indispensable, as Bergman properly observes; but hives should seldom stand in the shade. The apiary should be freed of weeds and tufts of grass close to the hive, as they harbour vermin: and spreading sand or gravel around the hives, is beneficial both in obstructing the growth of weeds, and in absorbing moisture. To save the trouble of atten-

dance, it is convenient to have the apiary in the vicinity of a dwelling house.

After the site of the apiary is chosen, it is necessary for the cultivator frequently to inspect his hives, to ascertain whether they are in a flourishing state, or suffer from disease and the inroads of enemies. Bees, in common with other animals, are liable to various diseases. The Abbé della Rocca informs us, that almost the whole hives in the isle of Syra, in the Archipelago, were destroyed by an epidemic disease which prevailed from 1777 to 1780. In this case, some vice or corruption seemed to originate among the young brood, which, infecting the bees, produced their death. A kind of dysentery or diarrhœa attacks bees at certain seasons, which is extremely injurious; the commencement is seen by the foulness of the combs, which must be pared, and the tainted portion taken away. Some cultivators pretend to cure this disease, which, they assert, arises from the nature of the honey collected, by supplying the bees with rosemary and honey diluted with water: others recommend a syrup, prepared with equal quantities of sugar and wine and a little nutmeg, a singular remedy: and a third class conceive a mixture of two pounds of clarified honey and as much sugar, with a pound of white wine, beneficial. Bees are likewise subject to a disease of the antennæ, which, though not dangerous, renders them dull and languid. It appears by discoloration like moulding, and is said to be curable by the preceding preparation. Toads, frogs, and mice, are reputed great enemies to bees: but we doubt whether it be truly so with regard to the two former, in this country at least; and the ravages of the latter are certainly not general. Perhaps, while the bees cluster together in rigorous winters, they may penetrate the hive and devour the combs; at other times it would be too dangerous an attempt even for animals better protected. Birds of several species, particularly swallows, sparrows, and red-breasts, are also ranked among the enemies of these insects: with respect to which, likewise, we should wish to see the facts better ascertained before giving them credit. Spiders and snails, which are considered noxious, can do little harm; for in this island there are very few, if any, of the former capable of contending with a bee, and the only damage done by the latter is soiling the hive. More dangerous are the larvæ of a small moth, hatching from eggs deposited within the hive, as they are destructive of the comb, and likewise the *sphynx atrofios* in its perfect state; but most formidable of all are wasps and hornets, and plunderers of their own species. The first two being strong and vivacious animals, are able to destroy living bees, and suck the honey from the abdomen; or they may penetrate the hive, and consume the comb. When a wasp tries to enter, it is resisted, but having made good its way, we believe it is then little regarded, and may leisurely satiate itself with honey. The nests of wasps ought to be carefully traced out and destroyed; if in the earth, by pouring boiling water down their hole, or kindling a quantity of straw where they are less accessible. Observers confidently affirm, that a whole swarm of bees, from defect of food and other causes, sometimes interrupt their natural collection, and becoming a band of plunderers, rob the stores of their neighbours. In this case, which will appear from the contests perpetually taking place on the boards and about the entrances of other hives, it is necessary to ascertain whence the depredators come, whether from neighbouring hives or

from those at a distance. If their plundering seems to arise from want of food, as those scanty provisioned are more apt to follow this method of supplying themselves, they must be fed at night when the sun is down, and while all the bees have returned. It is reported not to be an uncommon incident for a swarm to abandon their own hive, and take possession of another to relieve their necessities. Bees, on losing the queen, having no interest to prosecute their labours, if brood be wanting in their combs, sometimes begin to pillage the hives in the neighbourhood. The obvious remedy is here to provide them with a queen, whereby all their faculties being aroused, they will be reclaimed to their usual nature. Schirach warns us, on removing comb from a hive, to beware of scattering or dropping it, and to replace the hive exactly in the same position as before, otherwise the inhabitants of stronger colonies will obtain more ready access to attack the honey in the combs, or to collect what has fallen from them. The weakness of a hive is one great inducement for its neighbours to pillage; and as cleanliness, and being kept free of vermin, preserve the vigour and activity of its inmates, due attention to them should not be neglected. Removing the hive, which is the object of plunder, and covering it with branches, has been recommended; and such an expedient will certainly present a good chance of escape.

But all the devices adopted by us are poor and insignificant, when compared with those resorted to by the bees themselves to provide against danger. Here we have an opportunity of admiring that wonderful instinct, which animals, standing so low in the scale of creation, exhibit. Even supposing them to possess nothing analogous to reason; that the regard for their queen, and the watchful care of their young, result from some pleasurable sensation; that the massacre of the drones originates from some sudden principle of aversion,—we cannot refer their precautions to avoid danger to any relative source. It is evident that they labour in concert; that their operations tend to one general object; and that they are aware of it being fulfilled. Surely all this cannot be done without some mode of communication with each other: but considering that every thing they perform is in the dark; nay, that the perfection of their work is partly proportioned to the privation of light; the difficulty of conceiving how they can know each others proceedings is greatly increased. It has been warmly contested, whether bees are capable of imparting what we should call thought in beings higher in the chain of animated existence, and especially, whether there be any thing resembling voice among them? We have already remarked, that the workers can retain young queens in their cells after attaining complete maturity, which they are capable of doing by strengthening the seal or covering with additional wax; and that they regularly liberate the oldest of those of different ages. A sound, which we cannot compare to the buzzing of insects, by the balancers beating on their wings, is heard from the young queens. No researches, however, have yet detected the organ, if it is an external one, from which the sound proceeds. When a queen is hatched, she seeks the cells of those that will become her rivals, and uses every possible exertion to destroy them; but the workers, to which other queens, even in their imperfect state, are precious, generally present the most decided opposition, and render her attempts abortive. Yet, from the property which the

queen possesses of emitting that certain sound before heard from her cell, their resistance becomes vain; it paralyses all their faculties; and she proceeds to operate destruction. The following observations, by a distinguished naturalist, on this head, lead to an illustration of the peculiarities among bees when exposed to danger, though they more immediately relate to another branch of our subject. "The first of a number of cells containing females, opened on the ninth of June, and a young queen, lively, slender, and of a brown colour, escaped from it. Now we understood why bees retain the females captive in their cells so long after the period of transformation has elapsed; it is that they may be able to fly the instant of being hatched. The new queen occupied all our attention. When she approached the other cells, the bees on guard, pulled, bit her, and chased her away: they seemed to be greatly irritated against her, and she enjoyed tranquillity only when at a considerable distance from the cells. This proceeding was frequently repeated through the day. She twice emitted the same distinct sound or clacking that had been heard in her prison, consisting of several monotonous notes, in rapid succession: and in doing so she stood with her thorax against a comb, and her wings crossed on her back: they were in motion, but without being unfolded or opened. Whatever might be the cause of her assuming this attitude, the bees were affected by it: all hung down their heads and remained motionless. The hive presented the same scenes next day. Twenty-three royal cells yet remained assiduously guarded by a great many bees: when the queen approached, all the guards became agitated, surrounded her on every side, bit her, and commonly drove her away. Sometimes, when in these circumstances, she emitted the sound, and assumed the posture just described: from that moment the bees became motionless." Several queens were successively liberated, some of which had led out swarms; but eighteen cells still remained to be guarded. "The fifth queen left her cell at ten at night; and two queens were now in the hive: they immediately began fighting, but came to disengage themselves from each other. However, they again fought several times through the night, without any thing decisive. Next day, the thirteenth of June, we witnessed the death of one, which fell by the wounds of her enemy. The duel was quite similar to what occurs in the combats of queens. The victorious young queen now exhibited a very singular spectacle: she approached a royal cell, and took this moment to utter that sound and to assume that posture which strike the bees motionless. For some minutes we conceived, that, taking advantage of the dread shown by the workers on guard, she would open the cell and destroy the young female: and she in fact prepared to mount the cell; but in doing so she ceased to emit the sound, and quitted the attitude which paralyses the workers: the guardians of the cell instantly resumed courage, and by means of tormenting and biting the queen, drove her away."

These remarks are necessary to illustrate, how one of the principal enemies of bees can attain its ends with impunity. The *sphinx atropos*, which was long unsuspected, has recently been discovered to be a most formidable ravager of their stores. In years, when they had multiplied to an uncommon extent, whole districts of hives were plundered of all their honey: and it was not until after the injury had been done, that it was traced to its real source. Numbers of moths had made

their way into the hives, and satiated themselves with honey so long as it remained in the cells: and possibly as it decreased, the season when these animals abounded came to a close. But it must appear very surprising how a moth, quite unprotected with external means of defence, and liable, at the moment of its entrance, to be pierced by a thousand stings, each of which inflicts a mortal wound, can venture on so hazardous a pursuit. We must here recollect, however, that this identical insect is one, perhaps almost the only one, supposed to possess something like voice: and, at the same time, that the sound emitted by it bears a narrow resemblance to the peculiar sound proceeding from the queen bee, which paralyses the workers. It is thence far from improbable, that the first resistance opposed to the entry of the moth may be productive of this sound, which, though arising from accident alone, may have the singular effect of depriving the bees of the power of repulsion. If these facts be firmly established, and the conclusions just, it would be well worth the attention of cultivators to investigate whether any similar sound can be artificially produced, and whether it will have influence on the bees. They are perfectly aware of the presence of so redoubtable an enemy, and the danger resulting from it. In autumn 1804, the copious collections of honey which had been made during summer, had entirely disappeared, and the moths were uncommonly abundant. The owners of a number of hives resolving to protect them from further pillage, closed their entrances with tin gratings, where the apertures were proportioned to the size of the bees, on the 17th of September; but not having enough for the whole, two were left unsecured. It was seen next morning on examination, that, during the night, the bees had themselves taken the necessary precautions, by contracting the entrances of their hives, so as to make them quite safe against invasion. Each was completely blockaded by a wall, composed of old wax and farina, in which the bees had taken care to leave apertures corresponding to their own size: two, that would prevent above two bees passing at a time, were fashioned like inverted arches; a third was broad enough in front to admit of the passage of several bees at once, but so low, that they were obliged to lean over on one side to get through. All the other hives proved, on inspection, to be constructed in the same way, even where provided with the tin gratings. In other instances, the bees had constructed a double wall at the entrance of the hive, with covered galleries, so narrow, that no more than a single bee could pass: fifty-three swarms began these operations in the course of the same night. Bees, when attacked by plunderers of their own species, have been known to adopt similar precautions. On the 9th of July 1804, an observer having found some of those, belonging to a neighbouring hive, lying dead on the board of a swarm that they had come to pillage, watched the proceedings of the latter. On the 11th of the month, they had built up their entrance, leaving only two apertures at the part highest above the board, which would admit no more than one bee at a time: they were thus proportioned to the size of their enemies, and could be sufficiently guarded by two workers. But, in the sequel, they were enlarged, and on the 22d, they would have allowed two or three bees to pass at once. "Was this," the observer asks, "because they were sensible of having drones among them, for which these openings were too small?" No farina being in the country at that pe-

riod, the bees had built their wall of pure wax taken from the edges of their combs. In a subsequent fortification erected during September, they used farina along with the wax employed in it. It is important to attend to the circumstances which we have now exposed, for they demonstrate the precise plan that should be followed by a cultivator in protecting his hives. As the seasons of danger approach, he ought himself to diminish their entrances, an expedient which will prove the chief means of security. During the period of swarming, they should be left altogether free, but after that time, they must be contracted. When in danger of being pillaged by their neighbours, there may be only two apertures, each so large as to allow two or three bees to pass: and in countries where their great enemy, the *sphynx atropos*, abounds, the apertures, when the chief collection of honey takes place, must be made very low, that this insect may be excluded. Some observers have used a longitudinal or triangular cover of the entrance, turning by one corner on a pivot; by simply elevating or depressing which, the access was impeded or facilitated. An intelligent naturalist recommends adapting a slider, containing various apertures, at the entrance of the hive: merely by shifting it along, those suitable to the different seasons and conditions will be presented for the exit of the bees.

From the preceding remarks, the necessity of frequently inspecting hives is evident; not by tearing them from the boards, as is usually done, to the manifest destruction of the combs and derangement of the whole colony, but by examining the entrance with caution, and by using hives of such a construction that part of them opens to expose what is contained within. An apparatus of the description proposed by Bergman, should be kept for weighing the hives from time to time, that the increase or diminution may be known. This consists of a steelyard hung to a small frame: from one arm of the steelyard the hive is suspended by three slight chains, and a weight shifts along the other. The common iron spring steelyards may be conveniently employed, providing their accuracy has been previously ascertained.

When seasons are peculiarly unfavourable for the secretion of honey, sometimes, we have said, a whole swarm may perish in the middle of summer. Then or when they are deprived of too great a portion of their stores, it becomes the cultivator's care to supply the deficiency. There are various methods of doing so, always regulating the supply by the number of bees and the temperature of the atmosphere. The hive may be placed above a section of another hive containing several combs with honey; or combs may be laid on the boards of the hive before the entrance, which is less to be recommended from exposing the bees and their provisions to the invasion of strangers. Syrup of sugar, treacle, and other sweet substances, may be given them as food, introducing their allowance every afternoon in nutshells, or in a vessel with a grated covering, by an opening in the back of the hive. Unless the supply be daily administered, it is extremely difficult to preserve the bees; and by admitting of longer intervals, the most skilful cultivators have failed. A practical operator informs us, that he takes an oblong box, in one end of which is a reservoir containing honey, that is allowed to flow from the bottom of the reservoir under a thin float buoyed up by cork. This float has many small perforations, through which the bees standing on it supply themselves with the honey. There is one hole in the side of

the box, which is to be applied to the entrance of the hive, for admitting the bees above the float, and another on the opposite side, which is opened at pleasure, to allow them to escape, should the box be too much crowded. The lid of the box is a glass pane. On pouring honey into the reservoir, the float rises, whence there should not be such a quantity as to raise it close to the lid or pane above. The box is about ten inches long, four broad, two and a half deep, and the reservoir is an inch wide. When used, the hole in the side is to be placed close to the entrance of the hive, which must be gently rapped on if the bees do not immediately find the way down. It is entertaining to observe bees accustomed to be fed in this manner, watching the approach of the feeder; when the ordinary time draws near, they rush down to the box the moment that it is put on the board, and after speedily filling themselves they return to the hive, from which they very soon come back for a second supply. By throwing a little fine flour on those leaving the box, it will be seen that they can fill themselves in three minutes, and are absent not above five. One convenience that attends feeding in such a box, is the exclusion of stranger bees; as the sole communication with the interior is from the entrance of the hive. Several practical operators recommend a mixture of sugar and small beer as food, which we should warn others to be cautious of adopting, as they will find honey or syrup quite adequate to their purpose. It is maintained that fruit may likewise be presented to bees for feeding them.

Supposing, by a concurrence of favourable circumstances, that a hive is well provided with bees; that they are protected from enemies, their collections ample, and their brood abundant; the cultivator has to watch it strictly during the summer season when swarming takes place; it is only during the warmer weather that bees swarm, on fine days, and when the heavens are unclouded: if the sun be overcast, they hesitate to depart, awaiting the moment when he shines forth in full lustre. Though what are called precursors cannot be depended on, as we have shewn, they are not to be altogether neglected; and in attending to them the time of swarming will scarcely be overlooked. It is commonly between ten and three o'clock, sometimes a little earlier or later, that a swarm leaves the hive, during which interval the owner should be on the watch to follow it. A sudden buzzing is heard, the bees are seen in innumerable multitudes traversing the air in all possible directions, and the entrance of the hive soon appears deserted. After wandering about for some minutes, they are generally seen in small clusters, on some neighbouring shrub or tree, which gradually unite round the queen, and all are collected together in a single heap. If they rise high in the air, it frequently indicates their inclination to take a long flight, which is usually endeavoured to be checked by beating pans, ringing bells, and throwing dust or sand among them. The former can have little influence; if it does operate, it may be by producing a slight concussion of the air, which, alarming the bees in the same way as thunder, may induce them to settle; but the discharge of a fowling piece would have much more effect. Bees are conceived to mistake the dust and sand for rain, which they greatly dread; and we often observe them hastening to the hive on the approach of a shower, or when the sky becomes cloudy. Notwithstanding every effort to retain them, they sometimes rise very high, fly to a distance, and are irrecover-

ably lost. As they are said to fly in a straight line after having taken their direction, they must be pursued, as there is no other method of discovering where they alight. The place of their settling is extremely uncertain. Bonner says they will fly four miles to take possession of a dead hive, and affirms, that he has seen a swarm go into a living one that stood in the same apiary. If they alight in an accessible place, on the branch of a tree for example, after allowing them to settle completely, it must be gently cut off and laid on the ground, and a clean hive supported on two sticks put over it, and the whole covered with a sheet or large table cloth. The bees will soon ascend into the hive, and immediately begin working: late in the evening, when all is quiet within, the hive is to be transported to its station in the apiary. When the cultivator can, by any device, catch the queen and put her into the hive, all the bees will quickly follow. This is more essential to attempt, when the place where the swarm has settled is of difficult access; such as flying to the roof of a house, or the cleft of a tree. Then it is far from easy to dislodge the bees, which is, in the majority of cases, the sole method of recovering them; as we can hardly sanction the following method recommended by Bonner: "The owner should make as much room as possible to get his hand introduced, so as to pull them out by handfuls, and put them into an empty hive." Bees very quickly commence working even in the most exposed and unsheltered situations, unless removed to a hive. The operator should be provided with a dress to protect him from the stings of the bees: the best expedient is to have a close leather jacket and trowsers; the head and face covered, and goggles of gauze to save the eyes. Bees are less disposed to sting during their swarming than at all other times; and there have been instances of their settling on a person's head unattended by inconvenience. We have an authentic account of this from Tholey. "In the year 1717," he observes, "one of my swarms settled among the close twisted branches of a codling tree; and not to be got into a hive without help, my maid servant, being in the garden, offered her assistance to hold the hive while I dislodged the bees. Having never been acquainted with bees, she put a linen cloth over her head and shoulders, to guard and secure her from their swords. A few of the bees fell into the hive, some upon the ground, but the main body upon the cloth which covered her upper garments. I took the hive out of her hands, when she cried out the bees were got under the covering, and crowding up towards her breast and face, which put her into a trembling posture. When I perceived the veil was of no farther service, she gave me leave to remove it: this done, a most affecting spectacle presented itself to the view of all the company, filling me with the deepest distress and concern, as I thought myself the unhappy instrument of drawing her into so imminent hazard of her life. Had she enraged them, all resistance had been vain, and nothing less than her life would have atoned for the offence. I spared not to use all the arguments I could think of, and using the most affectionate intreaties; begging her, with all earnestness in my power, to stand her ground and keep her present posture; in order to which I gave her encouragement to hope for a full discharge from her disagreeable companions. I began to search among them for the queen, now got in a great body upon her breast, about her neck, and up to her chin. I immediately seized her, taking her from among the crowd, with

some of the commons in company with her, and put them together into the hive. Here I watched her for some time, and, as I did not observe that she came out, I conceived an expectation of seeing the whole body quickly abandon their settlement; but instead of that, I soon observed them gathering closer together, without the least signal for departing. Upon this I immediately reflected, that either there must be another sovereign, or that the same was returned. I directly commenced a second search, and in a short time, with a most agreeable surprise, found a second or the same. She strove by entering farther into the crowd, to escape me, but I reconducted her with a great number of the populace into the hive. And now the melancholy scene began to change, to one infinitely more agreeable and pleasant. The bees missing their queen, began to dislodge and repair to the hive; crowding into it in multitudes, and in the greatest hurry imaginable; and in the space of two or three minutes the maid had not one single bee about her, neither had she so much as one sting, a small number of which would have quickly stopped her breath."

Supposing that the cultivator desires to augment the number of his hives, without awaiting the period when swarming naturally ensues; or that his operation is checked by the uncertainties of weather, predominant in our climate above all others, he may resort to the expedient of obtaining artificial swarms. Several young queens originate at once in a hive; and the production of two is sometimes so immediate, that although both cannot survive together, they come off in the same swarm. As by M. Shirach's discovery, bees having lost the queen can procure themselves another, providing there be workers' brood in the combs, we can at pleasure rear successive queens simply by removing the first. If a hive is strong enough, therefore, it may be divided in two; one half will retain the old queen, and the other will not be long of obtaining a young one. Shirach directs, that the appearance of brood in a hive containing a queen is to be ascertained, which is always about the time that the trees are in blossom, or a little later in Britain. Three or four pieces of comb, with the brood, are to be cut out of the hive, and placed in a rack-work adapted in another hive in the same position as in that from which they came, and three or four hundred bees must be confined along with it; unless the hive be very large, they should not be numerous; and seven or eight hundred will always prove more than sufficient. Nearly fifteen days being requisite for the production of a queen, as much honey should be supplied every two days as will serve for subsisting the bees. The hive is then to be closed up and transported to a place where the temperature is moderate. Violent agitation ensues among the bees whenever they discover that they are imprisoned, and the tumult becomes still greater on their ascertaining that their sovereign is no longer with them. Silence succeeds, which is next followed by greater noise and confusion than what attends swarming. Immediately afterwards a new operation begins, and from the second day the construction of a royal cell is seen. The confinement of the bees must be protracted some days; but on the fourth or fifth, the hive may be carried into a garden, and the prisoners allowed to escape. Their eagerness to do so is such, that hardly one remains in the hive; however, in two hours they return to it again. The entrance must still be closed at night, and the hive carried into a house, unless the fineness of the weather admits

of it being left without. If the operator, on opening the hive, finds the brood hatched, and the royal cells well advanced, he should transfer the whole along with the bees into a dwelling of greater capacity, provided a small box has been used with three or four combs of white wax fixed near the top, that the interior may resemble a hive containing work already commenced. Should the queen be hatened, it will facilitate the operation if she can be transferred to the new dwelling: and thus the artificial swarm is formed. It is difficult to perform this operation with the common straw hives; but an expert person may accomplish it by means similar to those adopted in robbing the bees of their provisions.—Here the use of the book or leaf hive is especially demonstrated; for it affords facilities in forming artificial swarms infinitely surpassing any others that have yet been devised. Under the conditions above specified, of brood and population, the leaf-hive is to be gently separated in the middle, and two empty frames insinuated between the halves. The queen must then be sought for in one of the halves, and a mark put on her, in order to avoid mistake. Should she by chance remain in the division with most brood, she is to be transferred to the other containing less, that the bees may have every chance of obtaining another female. Next, it is necessary to connect the halves together by a cord tied tight around them: and care should be taken to place them on the same board which the hive previously occupied. The old entrance, now become useless, will be shut up; but as each half requires a new one, these ought to be made at the extremities of the two divisions, on purpose to be as far asunder as possible. Both, however, should not be made on the same day. The bees in the half deprived of the queen, ought to be confined twenty-four hours, and no opening made before the lapse of that time, except for the admission of air; otherwise they would soon search for the queen, and infallibly find her in the other division. But provided twenty-four hours be sufficient to make them forget their queen, this will not happen. When all circumstances are favourable, the bees in the division wanting the queen will begin to labour in procuring another; and about fifteen days after the operation, as before observed, their loss will be repaired. “The young female they have reared,” according to Huber, “soon issues forth to seek impregnation, and in two days commences the laying of workers’ eggs. Nothing more is wanting to the bees of her division, and the success of the artificial swarm is ensured.” The time of resorting to this expedient is, when the males are about to originate or actually exist: if attempted earlier, the bees will be discouraged by the sterility of their young female. The structure of the leaf hive enables us easily to ascertain the concurrence of the necessary conditions; for by simply opening the frames successively, their whole contents are exposed to view.

Should the original queen be accidentally lost or destroyed, the cultivator has still another means of preserving the whole colony, which, destitute of workers’ brood, would infallibly perish, by substituting a new one in her place. Bees are not immediately sensible of the loss or removal of their queen; their labours are uninterrupted; they watch over the young, and perform their ordinary occupations. But in a few hours agitation arises; all appears a scene of tumult in the hive; a singular humming is heard; the workers desert their young, and rush with delirious impetuosity over the surface of the combs. Then they discover that their queen is no longer among

them. There can be no question that this agitation is the consequence of bees having lost their queen; for should she have been intentionally removed, tranquillity returns on restoring her, and, what is very singular, she is recognised. If a stranger queen be introduced after the reigning one is lost or taken away, the agitation continues; the stranger is surrounded, seized, and kept captive by the bees in an impenetrable cluster, where she usually dies either of hunger or from the privation of air. If eighteen hours elapse, the stranger is at first treated in the same manner, but with less rigour; the bees gradually disperse, and she is at last liberated. But should there be an interval of twenty-four hours after the loss of the original queen before the stranger one is substituted, “she will be well received,” to use the words of an eminent author, “and reign from the moment of her introduction into the hive.” On this head, which it is extremely important for the cultivator to be intimately acquainted with, we are indebted to Huber for some interesting experiments. On the 15th of April, he introduced a fertile queen, eleven months old, into a glass hive, where the bees, having been 24 hours deprived of their queen, had already begun to construct twelve royal cells. Immediately on placing the stranger female on a comb, the bees in the vicinity touched her with their antennæ, and passing their trunks over every part of her body, supplied her with honey. These then gave place to others, by which she was treated exactly in the same manner. All vibrated their wings at once, and ranged themselves in a circle “around their sovereign.” Hence resulted a kind of agitation, which gradually communicated to the workers situated on the same side of the comb, and induced them to come and see what was going on. Soon arriving, they broke through the circle formed by the first of their companions, approached the queen, touched her with the antennæ, and gave her honey. After this little ceremony, they retired, and, standing behind the others, enlarged the circle. There they vibrated their wings, and buzzed as if experiencing some very agreeable sensation. In a quarter of an hour the queen began to move from her original position, when the bees, so far from opposing her, opened the circle at that part towards which she turned, and formed a guard around. While such incidents occurred on the surface of the comb where the queen stood, all was quiet on the other side. Here the workers apparently were ignorant of the queen’s arrival in the hive. They laboured with great activity at the royal cells, as if still ignorant that they no longer stood in need of them; they watched over the royal larvæ, supplied them with jelly, and the like. But the queen having at length repaired to this side, she was received with the same respect by the bees as she had experienced from their companions on the other side of the comb. They encompassed her, gave her honey, and touched her with their antennæ; and what proved better that they treated her as a mother, was their immediately desisting from work at the royal cells; they removed the worms, and devoured the food collected around them. “From that moment the queen was recognised by all her people, and conducted herself in this new habitation as if it had been her native hive.” Thus when bees have had time to forget their own queen, they receive one substituted for her with greater interest, or, perhaps, with more conspicuous demonstrations of it. The cultivator must, therefore, carefully practise one of two things when a queen is wanting in any of his hives; he has either to procure a

new one by supplying the bees with brood comb, whereby the loss will be repaired in about fourteen or fifteen days, or he must substitute some supernumerary queen, in which case the impending evils will be completely averted in twenty-four hours.

If two clusters of bees form in swarming, and remain quite separate and distinct from each other, it shews that two queens have left the hive at the same time. But no single swarm being too large, it is necessary, for the welfare of the community, that one of the queens be sought for, and sacrificed, on which the whole bees will unite. There are other situations when it is also beneficial to join two or more swarms together; such as when they are weak on leaving their hives in the summer season, or are sparingly provisioned or peopled towards winter. Numbers, we repeat, independent of affording a better security against external enemies, and in promoting the general activity, are more calculated in society to resist the inclemency of the weather. Those persons, therefore, who cultivate bees solely for the sake of profit, estimate according to the weight of a hive whether it be sufficiently strong. Hives under four pounds, being supposed to contain about 20,000 bees, are rejected; but Bonner affirms, that one consisting of 15,000 will do well, providing the season be not far advanced. The reader will not forget what we have observed of the discrepancies among naturalists concerning the number of bees in a given weight. The last mentioned author, who was a practical operator in uniting swarms, directs, that the mouths of two hives, the lower one full and the higher empty, are to be applied to each other, and a sheet, or large cloth, put round them. "The undermost hive must then be rapped with both hands, in the manner a drum is beat; rapping chiefly on those parts of the hive to which the edges of the comb are fixed, and avoiding the parts opposite to the sides of the combs, lest they should be loosened, and, by falling together, crush the bees between them, as well as the young in the cells. The more bees there are, the sooner will they run into the new hive; for the concussion of the hive by the rapping alarms them as an earthquake alarms mankind, and they run to the upper hive in search of a safer habitation. When the bees are thus removed into the new hive, it may be placed where the old one stood, which will collect all the bees together, and within ten minutes the bees will begin working as leisurely as any natural swarm." By this means the under hive will be left quite empty, and another may be substituted, in order that three swarms shall be united. Clusters of bees may also be introduced into a hive to strengthen it, and they are generally received without fighting. While the bees are very active, the places of a strong and a weak swarm may be interchanged; the number of the former which are out being much greater, will return to the latter as their own dwelling, and thus strengthen it. There is likewise an easy and simple method of uniting swarms, which consists in spreading a cloth at night on the ground, close to a hive where two new swarms are to be joined. One of them is to be brought, and put on a stick laid across the cloth, when, giving their hive a smart blow, they will drop down in a cluster. This done, and the empty hive thrown aside, the other should be expeditiously taken from its board, and set over the bees, which will speedily ascend into it, and unite with its inhabitants. By the means here described, a swarm may be increased to any given extent. Bonner assures us, that his mode may be practised in the mid-

dle of the day with little danger, and that he has taken off four swarms in one forenoon without a single sting.

It is ungrateful to reflect, that, after all our care in watching the progress of bees, in screening them from injury, added to our admiration of their singular industry, we must at once sacrifice so many thousand lives in order to come at their stores. Yet such is the general, though pernicious practice; and whole colonies, which, in another year, would send forth tens of thousands equally industrious as themselves, are utterly extirpated. The mode of doing so is well known. When the hives cease to increase in weight, or, rather, when they begin to grow lighter, a hole is dug in the ground, and some rags dipped in melted brimstone being inserted in the clefts of twigs stuck into the earth, the matches are kindled, and, putting the hive above them, the bees are quickly suffocated, and fall down in a heap. Some authors strenuously defend this practice, contending, that all expedients to save the bees are both difficult and precarious, and that they do not produce the same advantages. We conceive that its facility, combined with inveterate adherence to established customs, has proved a strong recommendation. But the majority of modern cultivators are disposed to preserve the bees, while they share their collections. Towards the end of September, when all the flowers have faded, when there is little brood in the combs, and the bees are beginning to consume the honey they have laid up, they may be frightened out of the hive by beating on it, and the combs then safely taken away. This, however, would reduce the owner to the necessity of feeding them during winter, whence an earlier season is generally chose for it, that the bees may still have time to lay in winter provender. The highest part of a hive being always filled first, and with honey of the finest quality, it may be taken in the midst of summer if the bees are kept in boxes, simply by removing the upper one, and substituting another below, if that be required. As every comb is seen in the leaf hive, any one of the whole can be removed at will, and new divisions inserted. The stores of the bees should be moderately partitioned with them, and due regard always paid to the advancement of the season, and the state of the atmosphere. We cannot tell how much they will produce. Thorley declares, that, in some summers, he has taken two boxes from one hive, each containing thirty pounds of honey. We hear of hives weighing seventy, eighty, or even an hundred pounds; but these bear no comparison with what M. Duhamel relates. A clergyman in France, who had placed a well-stocked hive over an inverted tub with a hole in the bottom, obtained no less than 420 pounds of honey and six of wax from it. The cultivator should know the exact weight of his hives, and mark their gradual increase or diminution, which will enable him to ascertain the proper time of taking the honey. Bonner judiciously observes, that "the harvest of honey, like that of corn, is earlier or later, more plentiful or scarce in different years, according to the weather and the climate, and the variety of the seasons and situations." Sometimes he has known a hive become gradually lighter after the first week of August; at other times, in favourable weather, hives situated near heath have continued working actively during the whole of August, and the greater part of September, and daily become heavier.

Of the practical separation of honey and wax we need say little, as it is universally understood by those who cultivate bees for profit. That honey which is most

fluid, and runs most easily from the comb, is considered the best and finest. To promote the separation of the rest, the combs should be cut into very small portions, and exposed before a fire, to render the honey more liquid; the product will be honey of the second degree of fineness; and the remainder should be heated still more in a vessel over a fire, and then squeezed through a canvas bag, which will produce a coarser kind, well adapted for feeding bees. It facilitates the operation, to erect a stage of three or four sieves, one always finer than the other from the top, and in a short time the separation is effected. Honey comb, wrapped in paper, and kept in a cool place, may be preserved entire during a whole winter or longer. To purify the wax, nothing more is necessary than boiling the empty combs, and those deprived of the honey, in water, and removing the scum which will rise in the successive meltings. The Abbe della Rocca proposes to put a quantity of comb, tied up in a linen or woollen bag, into a cauldron of water; as the heat increases, the wax liquefies, and, escaping through the interstices of the bag, rises to the surface, while the refuse is retained behind. This is a simple, and, as we conceive, very effectual method.

We apprehend that very few precautions are necessary for preserving bees in winter. They are not torpid in that season provided they be numerous, and then they cluster together towards the top of the hive. But, like other insects, they are liable to torpidity when single, or where there are few collected together, and that torpidity, by an extraordinary increase of cold, will end in death. With the view of saving their provision, it has been proposed to keep bees torpid, or in an ice-house all winter. It is undoubted that in a certain degree of cold they cease to consume honey, and animals may live an indefinite time in a state of torpidity. The hives ought not to be exposed to sunshine in the depth of winter, for the bees are induced to go out, and the sudden cold that follows deprives them of the power of returning.

The cultivation of bees forms one considerable branch of rural economy, and we could wish to see it much farther extended. This country is capable of supporting at least four or five times the number of hives now kept in it; and, without indulging in the speculations of extravagant profit, which are generally entertained by the authors who write on the subject, we will confidently affirm, that every one who attempts keeping bees on a moderate scale, and pays them some attention, will find it advantageous. There are repeated instances of bees swarming naturally three times during a season; and in the present year, 1810, we have known five swarms come from a single hive. Bonner calculates, that 20 stock hives in each parish of Scotland, or 16,000 in all, would, in seven years, by each merely producing one swarm, augment to above two millions and forty-eight thousand. He allows a deduction of forty-eight thousand for losses, which leaves two millions of stock hives. The loss, however, would be much more considerable; but from the parishes being about a fifth above what he supposes, the difference will not be proportionally great. Such an increase could hardly follow, and some unfavourable years might be destructive of most of the stock; yet, on the whole, the hives would be numerous compared with what they were in the outset. By another calculation, he supposes an individual purchasing five hives at 1*l.* each, will obtain, in ten years, 2560

swarms, which, valued at 10*s.* each, makes a profit of 1280*l.* He supposes that each hive gives one swarm annually; if they give more, that the latter are to be allotted for expenses and incidental losses. But in similar calculations we should hardly look further than three years; and it is quite moderate enough to say, that each hive will give one swarm, which may be preserved until the end of the third year. Therefore, as the price of hives in this year, 1810, is 2*l.* 2*s.*, supposing a stock of ten is obtained, it is far from improbable, that, at the end of the third year, it will be found to have increased to eighty; and it is likely, also, that other thirty or forty swarms have left the stock hives, or that first swarms have sent out a colony. The reasons we have already given shew why an excessive number of bees cannot be maintained in one place; and speculations in rearing them should be divided among several individuals residing in different districts. The trade of foreign countries in wax is very considerable; and the increasing demand for it may render the culture of bees more worthy of notice at home. In the year 1806, there was exported from the port of Mogadore, in Africa, 234,555 pounds of bees wax.

The honey bee is frequent in the wild state in warmer climates, but is very rarely to be found in Britain; nevertheless it is said to exist, and that a hive was discovered within these some years. Thus the animal may have either been domesticated at a very remote period by the inhabitants, or it may have been brought from abroad. Naturalists doubt whether the wild honey bee is a native of America, though existing in numbers in the woods. It is rather supposed to have been carried thither in the sixteenth or seventeenth century. Honey is said to be a great article of subsistence in Madagascar, and in other places where bees are common in the clefts of trees. In Africa, there is a small bird called *cuculus indicator*, or the honey bird, which, uttering a peculiar note, and flitting from bough to bough, will infallibly lead the traveller to a swarm in some hollow of a tree. See Swammerdam *Biblia Naturæ*. Maraldi *sur les Abeilles*, *Mém. de l'Académie des Sciences*, 1712. Reaumur, *Mémoires pour servir à l'Histoire des Insectes*, tom. v. The indistinct descriptions which some travellers give of the bees of different foreign countries, render it difficult for us to determine whether the real honey bee is meant or not. It is true, they describe such bees as being the same; but they maintain, that one species wants a sting, and that another nestles in the earth with its honey. So far as naturalists have yet ascertained, neither of these peculiarities belong to the honey bee; but it is extremely probable, that besides the single species which we keep in hives, others might be domesticated. One kind is found in Surinam, which hives

in very numerous societies. These construct a nest eight or ten inches in diameter, and eighteen or twenty long, towards the top of trees of moderate height. Within are found large cells of a fine reddish liquid honey, in great abundance. The nests, which resemble a lump of earth applied against the tree, cannot be procured unless the tree be cut down, when the natives of the country, after using the honey, and making a kind of mead, roll the wax around matches.

There is a species of bee which collects the honey of plants, and stores it up in cells, though we may doubt if this is intended for its winter provision. This is called the humming or humble bee; an insect so common in Britain as to have attracted the attention of every one. Like the honey bee, it lives in societies, consisting of from twenty to an hundred males, females, and what are supposed neuters. We have never found the society more numerous in Scotland, and the continental authors seem to describe it as smaller. These societies either dwell in cavities of the earth, or in tufts of moss collected together on the surface; or sometimes those whose proper habitation is in such cavities, are content with a hollow of the ground, where they cover themselves with moss and bits of leaves; or we have seen them effect a lodgement in a wooden box, some feet above the ground, in which they appeared to have themselves collected moss and leaves, and there bred a considerable colony. In reverting to the origin of these societies, we are opposed by very considerable difficulties. It seems probable, that a single female, which has been accidentally preserved through the winter, is the parent of the whole, and that she selects the spot, or cavity, for her posterity. No naturalist has, we believe, yet beheld a nest in its origin, though it has been seen when consisting of few cells. Reaumur relates, that on one occasion he removed the whole combs from a nest, and completely evacuated the interior. Nothing was visible for several days; but after the bees had remained eight days undisturbed, a lump of paste and farina the size of a nut was found in it, attached to which was a pot of honey; that is, a half made cell, which the bees at times construct, and in which some of their honey is kept. Thence, and from other circumstances, it is conjectured, that the mother proceeds to collect a quantity of farina or pollen, in the midst of which her eggs are laid; and by their coming to maturity after a certain time, the colony is constituted and enlarged. Several females inhabit the same nest, living in harmony together. They are occupied in collecting honey; and are easily known, from being the largest of all the three species. The males are next in size; always of a lighter colour; and are capable of making wax. The workers are of various sizes in the same nest, some not being half the size of others. Nature does not require the like sacrifice in the males of humble bees as in those of the honey bee to propagate the species; the sexual union takes place according to the common mode of insects: neither is there any massacre among them. Females and workers are much less disposed to use their stings than the honey bee: here, also, the males have none.

On opening a nest containing a colony of humble bees, a confused and mishapen aggregate of ovoidal substances is disclosed, interspersed in various parts with crude masses of wax, and cells of honey. The ovoidal substances are the young coming to maturity, within a

silken cocoon coated with wax; and amidst some of the lumps of wax are found larvæ, which one author thinks are there for the purpose of being fed, and another for being preserved from cold and humidity. The eggs are deposited in cells, which the workers lend their aid to construct; and the mother herself completes them, smoothing and polishing the interior. When she prepares to lay in a cell, the workers, unlike that care which those of common bees bestow on the eggs of their queen that are to preserve the colony, eagerly endeavour to devour them. The moment that the eggs are deposited, and the female is about to close the cell with a waxen covering, they rush upon it, and are repulsed only by her defence; or, if she removes during an instant, they steal thither, and surreptitiously carry off the eggs. The female is, therefore, under the necessity of keeping incessant watch during several hours, after which she may leave the cell; for it is only in their first stage that the eggs are sought for with avidity by the common bees. Sometimes twenty eggs are deposited by a female in a single cell, which is then closed; but it does not appear that the bees are careful to provide the young with a sufficient store to serve them until their ultimate metamorphosis; for the mother supplies a thick layer of pollen whereon her eggs are deposited, which is soon consumed by the larvæ. After being hatched, the common bees make a small hole in the top of the cell, and then go in quest of honey or pollen. This they obtain from the rest of their combs, and seem to introduce it by the opening to feed the young; they then withdraw, and close the cell. Some cells acquire perceptible increment; from being very small they become as large as a nut; which results from the included worms, perhaps six or seven in number, successively bursting the cell, and the cleft being as often covered over with wax by the bees. When the young bee has attained its perfect state, the workers gradually contract the mouth of the cell it has left, and lay up their honey in it. Other cells are also constructed of pure wax, which are so many reservoirs of honey from the beginning, and have never contained young.

Humble bees form a very considerable quantity of wax; and the observations of naturalists regarding them has thrown some light on the production of this substance. Several species, both of those that dwell in cavities of the earth, and those that inhabit nests covered with moss on the surface, invest their whole combs with a waxen envelope, so as to serve for a protection. It rises around their combs like a kind of wall, and constitutes both a floor and a roof, at such distance from the cells as to admit of the bees passing. When their envelope is destroyed, the bees restore it with wonderful assiduity. An observer by removing it four times in nine days, obtained as many new coverings, which formed eight inches square; and in four or five days more they made a new one, which, along with the others, weighed 365 grains. Instead of this covering, however, they are frequently obliged to be content with moss or leaves. Females produce a greater quantity of wax than any of the other individuals in a nest; but the males produce it also, though they cannot, like the females and workers, convert it to use. The wax of humble bees is an immediate production from the honey on which they feed. M. P. Huber, the son of the eminent naturalist of that name, inclosed a certain number of humble bees under a glass receiver. They ranged

themselves in a circle around some honey which they were supplied with, and, extending their trunks, led during ten or fifteen minutes. Then they brushed themselves with their feet, to be freed of the particles of wax which transuded between the rings of the body. Repeated experiments proved, that it was instantaneously produced, and the same bees afforded a quantity daily.

Humble bees are remarkably subject to torpidity, and perhaps might be the means of illustrating the difficulties attending all investigations into its operation on insects. Towards the end of autumn they are seen languid and inactive on the few remaining flowers, incapable of defending themselves from injury. The life of the whole apparently terminates with the season, unless it be from some accidental circumstance, as we have already observed, that a few of the females are pre-

served. How they survive the winter we know not; possibly it may be in the earth, or in the holes of walls; but the number must be very small. Were they not in torpidity they would fly about during the winter, which is never seen; and the same degree of heat would awaken the whole, or there would be no considerable difference, unless by their being farther withdrawn from the influence of the atmosphere. Very few, however, appear in spring; and it is not until the heats of summer, or rather later, that they become numerous. The casualties to which these and many insects are exposed, render it far from improbable, that various species gradually become extinct. See Gødartius *De Insectis*. Swammerdam, *Biblia Naturæ*. Geoffroy, *Histoire Abrégée des Insectes*. Reaumur, *Memoires*, tom. vi. P. Huber *On Humble Bees: Transactions of the Linnaean Society*, vol. vi. (c)

With respect to the venom of the bee, it appears to be a liquid, contained in a small vesicle which is forced through the hollow tube of the sting with the wound inflicted by that instrument. Fontana observes, that the poison of the bee, as well as of the wasp, bears a striking resemblance to the poison of the viper. The following interesting remarks on the nature and policy of bees, drawn principally from observation, are given by Bonnet (*Contemplation of Nature*.)

“The government of the bees more nearly resembles the monarchical than the republican. In that, a single bee governs the whole. This bee is not only the queen of the people, but is likewise their mother in the strictest sense. Among thirty or thirty five thousand bees, of which a hive frequently consists, the queen is the only one that breeds. It is to this prerogative, which is a more real one than many of those which distinguish sovereigns, that she is indebted for the extreme affection her subjects bear her. She is almost continually attended by a circle of bees, who are solely employed in endeavouring to render themselves serviceable to her. Some present her with honey, others pass their trunk lightly to and fro on her body, in order to remove from it any thing that may be offensive. When she walks, those that are in her passage range themselves in a proper manner to make way for her. They either know, or seem to know, that this procedure has an important object in view, that of augmenting the number of citizens.

Indeed she is at that time in search of proper cells for the reception of her eggs. These cells are like those of the wasps, of an hexagonal form, but their lower part is made with much greater art: instead of being nearly flat, it is pyramidal, and composed of three even and similar lozenges, so proportioned, that they unite in them these two remarkable properties; the first, that of giving the greatest capacity to the cell; and the second, that it requires the less matter for its construction.

The architecture of the bees likewise surpasses that of the wasps in the disposition of the combs: the latter have only one range of cells; whereas the management of the former is much more advantageous, each comb has a double range of apartments. They bear against each other at the bottom, so that the aperture of those

of one range faces, on the opposite side, that towards which those of the other range are turned. Their axis is parallel to the horizon, and the comb they compose is perpendicular to it. This position, which is directly contrary to that of the wasps, is determined by particular circumstances, and the preservation of the young depends upon it.

The neuters, or *labouring bees*, form these combs, in which there appears so excellent a geometry. They collect the matter for them from flowers. The wax is made of the dust of the stamina. They prepare this dust, and digest it. They make little masses of it in their hives, either for the contributing to the construction of new combs, or to serve them for food.

Whilst one division of the bees are employed in collecting the matter of the wax, and in preparing and filling the magazines with it, others are busied in different labours. Some work this wax and build the cells with it; others polish and perfect the work; whilst others reap a fresh harvest from the flowers, by the honey they extract from them; which they afterwards deposit in the cells, for the necessities of each day, and those of the inclement season. Others cover with a lid of wax the cells that contain the honey, intended to be preserved for the ensuing winter; a precaution which prevents any alteration in it. Others feed the young. Some are employed in fixing a wax lid to the cells of such as are about to metamorphose themselves, that they may do it with the greatest certainty. Others close, with a kind of pitch, the smallest crevices in the hive, through which the air or small insects might gain admittance. And others, in the last place, carry out the carcasses, which might infect the hive by their corruption: such as are too large to be removed they cover with a thick layer of wax, or a kind of gum, under which they may putrify without causing any inconvenience.

In order to facilitate all these different works, the labourers take care to leave distances between the combs, that are like so many streets, whose width is proportioned to the size of the bees; they are likewise skilful in contriving doors to each of the combs, by means of which they avoid going round about.

The queen animates the labourers by her presence, which is more literally true than is commonly imagined.

If a swarm be divided, that part which is deprived of the mother will perish, without constructing the least cell; whilst that part which is governed by the mother will replenish the hive with combs and provisions of every kind.

The labour of the bees is generally in proportion to the number of eggs the mother is to lay. So that the greater her fecundity is, the more numerous will be the combs that are formed by the bees.

It would notwithstanding be in vain to attempt to induce the neuters to make more combs, by introducing several mothers into the hives; for the supernumerary mothers would be presently put to death. The constitution of the society admits of no more than one.

The males, which are infinitely fewer in number than the neuters, but however abundantly numerous for a single female, bear no part in what is transacted in the hive; their whole occupation is confined to fecundation only, and they cannot betake themselves to that without some degree of pains: the queen must make the first advances, and excite, by reiterated caresses, the favourite on whom her choice happens to fall. We have seen elsewhere, that this inversion of the general order is founded on very wise reasons. The males are nourished and provided for till about the month of August, at which time, being found to be useless and even burdensome to the community, the neuters exterminate them entirely. They are apprehensive, that were they to preserve them alive, they themselves would perish with hunger during the winter.

However, at the return of spring, male bees appear again in the hive, and even several females may be discovered among them, and the number of neuters likewise increases daily. The extreme fecundity of the mother occasions this numerous offspring.

Lastly, there issues from the hive one or more swarms, each of which have a queen at their head. These are colonies which go in search of an establishment elsewhere, which they are not able to find in the metropolis, being overcharged with inhabitants.

The sight of a bee-hive is certainly one of the finest that can offer itself to the eyes of an observer. There appears in it an astonishing air of grandeur. One can never be weary of contemplating these workshops, where thousands of labourers are constantly employed in different works. We are struck in a particular manner with the regularity and geometrical exactness of their works; as we likewise are at the sight of their magazines, which are replenished with every thing necessary for the support of the society during the rigorous season. We likewise stop with pleasure to behold the young ones in their cradles, and to observe the tender care of their nursing mothers towards them.

But what chiefly attracts the attention of every one is the queen; the slowness, I had almost said gravity of her march, her stature, which is a more advantageous one than that of the other bees, and, above all, the various homage paid her by the rest, characterise her in a distinguishing manner. We can scarce believe what our eyes are witnesses of, on observing the regard and assiduities of the neuters for this beloved queen. But our amazement is greatly heightened when we see these laborious active insects entirely cease from their labour, and suffer themselves to perish as soon as they are deprived of their sovereign.

By what secret engagement, by what law superior to

that whereby each individual provides for its own preservation, are the bees attached to their queen in such a degree, as absolutely to neglect the care of their own lives, when they happen to be separated from her? This tie, this law, seems to be nothing more than the grand principle of the preservation of the species: the neuters do not engender; but they know that the queen enjoys that faculty: they construct those cells, whose proportions we so much admire, for the reception of the eggs she is ready to lay. Nature has intrusted them as much with regard to the young that is to be hatched from them, as she has the mothers of other animals in favour of their offspring.

But it will be asked further, how the mere presence of the queen can excite the bees to their labour, engage some to erect cells, others to collect and amass wax, and others to gather honey, &c.?

May not this be the effect of a certain impression purely physical? May not the eggs which the body of the parent bee is full of, affect the rest by means of the smell, or of some other sense unknown to us?

Be this conjecture as it may, we are not to suppose that the presence of the queen is capable of making different impressions on different bees, by determining some to construct the cells, others to store up the wax, and others the honey, &c. The impression in question is one, it prompts the bees to labour; but this labour is different according to the particular circumstances wherein each bee is placed; for example, a bee goes out from the hive; there is no room to think that this is with a fixed design of gathering wax rather than honey; but she meets with a flower that abounds with the dust of the stamina, and affords but little honey; therefore she loads herself with the matter for the wax. We must also remark that this crop is principally reaped in the morning. At that time the fine powder of the stamina is not dried up by the heat of the sun, it preserves a certain humidity which connects the grains of it, and thus renders the collecting and transporting it more easy. The honey, on the contrary, being a juice which exudes from the flowers by the action of the sun, they afford but little of it in the morning; the middle of the day is the most favourable time for this kind of harvest; consequently we see very few bees at that time return to the hive loaded with wax, the greatest part of them bringing honey.

But how comes it to pass, that the bees, when deprived of their mother, suffer themselves to perish for want of nourishment? How is it possible for them to forget to such a degree the care of their own life? This must be the case if they construct no combs: their reasons for this proceeding are pretty apparent: but they might at least collect from the flowers as much honey and wax as are necessary for their present subsistence.

Here the ultimate cause is pretty evident: the preservation of the species is of more importance to nature than that of individuals: in the present case, where the former could not take place, the latter would become useless. With regard to the efficient cause, it is not easy to penetrate into it. Can the neuters be absolutely divested of the sense of hunger? Are they only induced to collect wax and honey, and to feed upon it, merely from the agreeable impression the sight of the matters on the flowers produces on the organ? This would be very singular; for hunger is a sensation common to all animals, or seems to be so. It is a means wisely esta-

blished, to prevent the destruction of individuals, by exciting them to repair the continual losses which the different evacuations occasion. But in the choice of the method in question, nature could not propose to herself as a principal object the preservation of individuals, as individuals, but rather as the authors of generation, or the preservers of the species. In fact, amongst quadrupeds, birds, fishes, reptiles, and almost all insects, each individual is either male or female, or both together, as earthworms, snails, &c. In them we see that the preservation of the species immediately depends on that of individuals. The case is not the same with respect to the bees: the greatest number of those that compose the same society is deprived of the distinction of sex, and only contribute to the preservation of the species in quality of a secondary cause. It will not therefore seem improbable that the neuters are deprived of the sense of hunger. We see plainly that the queen and the males cannot be deprived of it; forasmuch as they eat frequently.

But if the neuters are not capable of feeling hunger, how are they prompted to repair their strength which is exhausted by labour and perspiration? The neuters, which have a queen at their head, are excited to labour by her presence. They cannot attend upon the various labours they are charged with, without finding frequent opportunities to take nourishment. The reason is, that independently of the agreeable sensation which may result from the action of the wax and honey on the organ of the neuters, these matters must necessarily pass through their stomach, and be there digested and prepared, before they are deposited in the hive, to answer the uses for which they are designed.

It will perhaps be objected that it is strange, that amongst individuals of the same species, there should be some of them endued with a sensation altogether unknown to others. But is it not equally strange, that amongst these same individuals, some are provided with organs which are not to be found in the rest? The labouring bees have some, which are not to be seen either in the queen or the males; and these, on the other hand, have likewise such as are not perceived in the working bees. The destination not being alike for all the individuals, the means corresponding thereto must necessarily differ.

Another reflection offers itself in support of the conjecture I have ventured to advance: hunger is a pressing, active, and restless sensation; now the neuters, when deprived of their queen, fall into a kind of drowsiness which continues as long as they live. If during this state of lethargy we give them a queen, they immediately awake, and betake themselves to work.

With a view to discover the fundamental law of the government of our republican bees, a hive has been divided into two nearly equal parts; and it has been always observed, that such bees as had no queen, made no combs. This alone was a very decisive experiment: but there remained another still to be tried; and that was, to divide a hive that was well stocked with combs, inhabitants, and young, and to trace attentively all that passed in that part of the hive where the queen was not. One would naturally conjecture, that the neuters would continue their diligence in the education of the young, and that they would not cease working till the latter were become bees.

By a very simple method, two hives are obliged to make a reciprocal exchange of their hives and combs: they are reconciled to this change, and the neuters of each hive take the same care of the young they find in their new habitation, as if they were their own proper nurslings. The affection of the neuters then extends itself indifferently to all the nymphs. Therefore this instinct has a direct relation to the preservation of the species. It is necessary to vary in some measure this experiment, in order to sound the discernment of the neuters, and to substitute with skill the nurslings of a different species instead of those of their own.

The neuters are of neither sex; they do not procreate, how then can we suppose that there is precisely the same affection in them towards the young of their queen, as resides in the mothers of other animals? Notwithstanding which, they act like them in the same circumstances. If then nature has been enabled to interest the attachment of the mothers, by the agreeable sensations their young occasion them to experience, or by the services they derive from them, it is highly probable that her proceeding is nearly the same with respect to the labouring bees, and that she has implanted in the young, towards them, a secret cause of agreeable sensations, whereby they are attached to them, and induced to disgorge into their cradles that kind of nutriment which contributes to their nourishment.

We have seen, that if several queens be introduced into a hive, there will never be more than one to hold the reins of government: all the rest will be put to death. We are not yet thoroughly informed, whether the dominion always vests in the lawful queen, or how and by whom the supernumerary queens are sacrificed. It is not probable that the neuters are charged with these cruel executions: they pay the same homage to strange queens as to their lawful sovereign. But the queens are armed with a strong and sharp sting, and we cannot sufficiently account for the utility of this offensive weapon, if they do not employ it either for defending or acquiring a throne. Be this as it may, we can clearly comprehend why it was ordained, that there should never be more than a single queen in each hive. A swarm, how numerous soever it may be, is hardly ever too much so for one mother only; which in the course of a year can easily lay fifty thousand eggs. A proportionable number of cells is requisite for these eggs; and all of them are not employed for lodging the young. Thus it happens, that when the hive is somewhat defective, the mother is obliged to deposit three, four, or five eggs in the same cell, and as there is not sufficient room in each for any more than one at a time, the supernumeraries are always sacrificed, which is a loss to the republic.

It is unquestionably the office of the neuters to exterminate the males, when they are become useless to the community. But do the neuters know that they would perish with hunger were they to preserve them? It is highly probable their sagacity does not extend so far. Suffice it to admit, that there is a certain time when the males make such an impression on the senses of the neuters as tends to irritate them, and prompts them to destroy them.

Whilst the season continues favourable for collecting honey and wax, the neuters never cease to gather it, and fill the magazines. Not that they can foresee long

before-hand that a season is nigh when these harvests will be denied them. It would be very unphilosophical to attribute such foreknowledge to bees. Can beings that neither have, or can have pure sensations, pry into futurity. All has been so well ordained, that the bees are furnished with provisions, without thinking or being capable of thinking of any precautions necessary for that purpose. They have been instructed to gather honey and wax; they apply themselves to it during the summer season, and on the return of winter, the combs are always filled with wax and honey.

Are these combs, in which such profound skill in geometry is displayed, indeed the work of geometrical insects? The more geometrical the work appears to any one, the less geometry he supposes in the workman. It is self-evident, that here the geometrician is the *author* of the insect. The latter executes a work by a kind of mechanism, whose proportions a Koenig and Cramer calculate with astonishment, but cannot account for them. That understanding which is able to form a perfect idea of the body of a bee, will doubtless perceive in it that little machine, which constructs these cells so economically regular. It would judge of the effects resulting from this machine, as a mathematician judges of those of an engine, or any other machine. Let us judge from this piece of skill, which is of itself so decisive, of the other operations of the bees. Can we think that they are less mechanical? We will not advance that bees and all other animals are mere machines, clock-work, engines, &c. There is perhaps a soul connected with the machine; it is sensible of its motions, is pleased with them, and receives from the machine agreeable or unpleasant impressions, and this *sensibility* is the ground and sole mobile of the animal. This example alone will be sufficient, one would think, to convince every judicious reader, how greatly we are mistaken in bestowing so liberally on animals our method of thinking and reasoning, and almost our disposition itself. To be satisfied of this, we need only apply to the construction of the honey-combs those ideas of reasoning which we adopt with so little reflection in favour of bees, and we shall transform them at once into sublime geometricians. They would then likewise be acquainted with botany; for they know perfectly well, perhaps better than we do, those parts of plants in which the sap is contained.

Notwithstanding all the attention which the greatest observers have bestowed on bees, there still remain many more interesting things to be shewn to us than they have hitherto discovered. It will be particularly needful for them to contrive a method for procuring a clear inspection of them, whilst they are busy in forming those minute lozenges which are the base of the cells, and the most curious part of the work: By dint of observation they will at length discover such particularities as will unravel the mystery of the mechanism I spoke of. The bees always flock together in such numbers when they begin to construct a comb, that it is hardly possible to discern their manner of working. An essential point would be, to cause but a small number of labourers to work at a time. The observer knows how to turn himself about, to invent, and to draw new instructions and views even from obstacles themselves. The study of natural history seems to be the best adapted for perfecting the sagacity of the human mind.

We will remark as we conclude, the singularity of the means the *AUTHOR* of nature has chosen for preserving the species of bees. We are presented with three kinds of individuals, that may be called three distinct species. The mothers, which are almost every-where besides so taken up with the care of their young, we find here only give them birth. Other mothers, nursing mothers, bring them up, and have the same regard for them as though they had given them being. They not only tend, nurse, and protect them, but likewise frame the nests and cradles appointed for them to grow in; and the construction of these nests is executed with so much art, and the ground-work and matter of them so skilfully contrived, that it cannot be justly estimated but by styling it an excellent piece of geometry."

On the subject of the bee that constructs its nest with a sort of glue, and the tapestry bee, the same author observes :

"In treating with rapidity of the various proceedings of insects, relative to the manner in which they deposit their eggs, I spoke of a very curious nest which a solitary bee formed with pieces of leaves. I represented it to be composed of a series of cells, and joined together as thimbles are for sale in a shop. I described the prodigious art displayed in the construction of this nest, each cell of which is formed of several fragments of leaves, cut, rolled, and collected with equal exactness and propriety, and as capable as a closed vessel of containing liquor without danger of its ever running out. Lastly, I set forth, that this assemblage of cells, so regularly and skilfully cut out, is covered over with one general foldage, of the same matter with the cells, and resembling the form of an instrument-case.

This nest, which I have now given an idea of, is hid under ground. The bee there digs a cavity proportioned to the size of the case. We are also to seek under the earth for the nest of another solitary bee, whose industry is little inferior to that of the leaf-cutter, and that works almost on the same plan. Its nest is likewise composed of several cells, artfully let into each other; but are not covered with a common inclosure. Each cell consists of two or three membranes, placed on one another, and are inexpressibly fine. Examine with the microscope, they present you with nothing that may give room to suspect they were not taken from plants. One would imagine them to be of a pure silky nature, and of the finest white. But the bee does not spin: what then must the matter of these membranes consist of, which appear so fine, so glossy, and white? By observing attentively the cavity in which the nest is inclosed, we shall find it smeared with a slight layer of glossy matter, exactly similar to that of the cells, and may be compared to that viscous humour which snails spread in their passage. A bee has undoubtedly an ample provision of this kind of glue, which she employs with so much art: but as she works under ground, and in profound obscurity, we have not yet been able to surprise her at her labour. Notwithstanding the extreme delicacy of their membranes, the cells have a sufficient degree of consistence, and may be handled without altering their form. The *paste* contained in them supports their walls, and prevents their giving way. This paste is a kind of wax, moderately tempered, and sometimes not at all. An egg is deposited at the bottom of each cell. After it is hatched, the worm finds itself in the

midst of a plentiful stock of provisions. It acts with a kind of intelligence in the manner of consuming, and seems to conduct itself as though it would preserve a necessary prop to the walls of the apartment: it does not dig into the paste in all parts, but scoops it perpendicularly from the bottom to the top: it forms by this means a little stalk, which occupies the axis or center of it. As it increases in growth, it enlarges this stalk, extending it in length and width. At length it arrives at the walls; and has then consumed all the paste, and completed its growth.

Many species of solitary bees content themselves with penetrating into the earth; scoop out cylindrical cavities therein, and polish the walls. They deposit an egg there and amass a sufficient quantity of nourishment.

There is another species of these worms that pierce the earth, whose industry is much more remarkable. They do not content themselves, like the others, with an entire naked cavity. On visiting the inside of the lodge, immediately after its construction, we are agreeably surprised to see it hung quite round with tapestry of the most beautiful crimson satten, affixed to the sides as our tapestry is to the walls of our apartments, but with much more propriety. The bee does not only line in this manner the whole inside of her dwelling; but also spreads the same kind of tapestry round the entrance to the distance of two or three lines. We have observed many caterpillars that line the inside of their cone or inclosure with silk: our bee is the only insect at present known, which, properly speaking, hangs her nest with tapestry, as we do our apartments. It is therefore with good reason that this industrious animal has received the name of the tapestry-bee.

You are impatient to know from whence she procures the rich tapestry. Look at the flowers of the wild-poppy, which are newly blown: observe that they are sloped here and there. Compare them with the tapestry whose tissue you are desirous of knowing, you can find no difference between them: this tapestry is no other than the fragments of the flowers of the wild-poppy; and that is the secret origin of those slopings you remark on the poppies that border upon the nest. Your curiosity is not yet satisfied; you are desirous of observing a little the labour of our skillful worker in tapestry.

The hole, which she digs perpendicularly into the earth, is about three inches in depth. It is exactly cylindrical, as far as to seven or eight lines of the bottom. There it begins to open wider, which it does more and more. When the bee has made an end of giving it the suitable proportions, she proceeds to line it with the tapestry.

With this view, she applies herself to cutting, with abundance of art, pieces of petals of an oval form from the flowers of the wild-poppy, which she seizes with her legs, and conveys into her hole. These little scraps of tapestry, when transported thither, are very much crumbled; but the *tapestry-bee* knows how to spread

them out, display them, and affix them to the walls with astonishing art.

She applies at least two layers of the petals. She spreads two tapestries on each other. The reason of her furnishing herself with it from the flowers of the wild-poppy rather than from those of many other plants, is, because in them are united to a higher degree all those qualities which are requisite for the use to which the bee designs to put them.

When the pieces which the bee has cut and transported are found to be too large for the place they are intended to occupy, she cuts off the superfluous parts of them, and conveys the *shreds* out of the apartment.

After hanging the tapestry, the bee fills the nest with *paste*, to the height of seven or eight lines. This is all that is necessary for the nourishment of the worm. The tapestry is designed to prevent the mixture of particles of earth with the paste.

You expect undoubtedly that the prudent bee should not fail to close up effectually the aperture of the nest in order to hinder the access of those insects into it that are fond of the paste: this she takes proper care to do: and it is utterly impossible for you to discover, from the surface of the ground, the spot where the nest was, whose construction you have just been contemplating, such is the skill employed by the bee in closing it. This little white pebble was at the edge of the hole, or very near it; it has not changed its place, and indicates to us the part beneath which the nest is we are searching for. It seems then as if we should have nothing more to do than to raise up a light layer of earth, in order to expose to view the entrance of the hole which has been so well closed. Nothing can be easier or less doubtful. How great is your surprise! you have already taken up two or three inches of the earth in depth, and you cannot find the least appearance either of the hole or the tapestry. What can this mean? What is become of the nest that was so skilfully constructed, so properly lined, and was upwards of three inches deep? A few hours since, you admired the ingenious contrivance of it, and now the whole has disappeared, so that you cannot discover the least trace of it. What mystery then is this? It is effected as follows:

When the bee has done laying, and amassed her quantity of paste, she takes down the tapestry, folds it over the paste, which she wraps together in it pretty nearly as we fold on itself a coffin of paper that is half full. The egg and paste are by this means inclosed within a little bag of flowers. The bee has then nothing farther to do, but to fill up with earth all the void space that is above the bag; and this she performs with such wonderful activity and exactness, as utterly to conceal the place where the nest was."

Nothing can be more sublime and instructive than the economy of the bee. Such facts, therefore, as have been adduced on so interesting a subject, cannot fail to call our attention to the beauty and harmony, order and industry, which the hive presents. CUTBUSH.

BEEN, the name of a musical instrument used in India, resembling the guitar. See *Asiatic Researches*, vol. i. p. 295. (w)

BEER. See BREWING.

BEERING, BEHRING, or BERING'S ISLAND, lies in the North Pacific Ocean, in 55° North Lat. and about 167° of East Long.: the southern extremity bearing north 67° from the harbour of St Peter and St Paul, 192 miles distant. It is 104 miles in length, and 15 in breadth: the west side mountainous, but the northern point low land: the mountains are of granite and sandstone, and in their recesses contain many caverns. There are two bays in the island, whither merchantmen engaged in the fur trade are wont to winter; but they are shallow, of dangerous access, and exposed to the north winds. Minerals of value have been said to exist here; and sometimes after violent storms, pieces of native copper are cast ashore.

This island, which some geographers incline to unite to the Aleutian isles, while others detach it from them, was discovered by Commodore Behring, a Dane, who is mentioned in the subsequent article. He and Captain Tschirikow left Kamtschatka on a voyage of discovery, in 1740, and sailing northward, made the coast of America, in 60° of North Lat. They afterwards encountered continued tempests, in which they lost their reckoning, and were tossed about in unknown seas. In endeavouring to regain the coast of Kamtschatka, they came in sight of Behring's island, in November 1741, under circumstances of uncommon distress. Great sickness prevailed among the ship's company; and the Commodore himself, incapable of motion, was carried ashore by his people. But the island being utterly destitute of shelter, they had recourse to holes in the ground between the rocks, which they covered over with sails, to exclude the rain and snow, it then being the winter season. Behring was lodged in one of the most commodious of these, and a kind of tent was erected over him. But the sand within the hole falling down, covered his feet every moment: at first it was removed; thinking, however, that it somewhat promoted the vital warmth, he would not allow it to be taken away. Thus he remained until the gradual accumulation of the sand covered him up to the belly, and then he sunk under the severity of hardships, combined with a painful and lingering disease. His remains were actually dug out of the earth, that they might be restored to it in a manner more creditable to the memory of a gallant officer; and to preserve them from being devoured by ravenous beasts of prey. Many more of this unfortunate crew fell victims to the same evils; and among them M. de la Croyere, an astronomer, who had embarked for the purpose of discovery. On board also was M. Steller, a naturalist, one of the royal academicians of Petersburg, to whose narrative we owe some of these particulars, though he did not himself survive to return to that metropolis. To complete the disasters of the Russians, their vessel was totally wrecked, and they were compelled to winter on Behring's island, almost entirely destitute of shelter. At length they contrived to build a bark out of the fragments of their ship, in which the survivors reached Kamtschatka. It is not to Behring only that the island, bearing his name, has proved fatal. In the year 1787 or 1788, an English vessel, built solely of mahogany, (as is said,) commanded by Captain Peters, sailed from Bengal, with the design of collecting copper at Behring's or Copper island. After a successful traffic

with Kamtschatka, Oonalashka, and other parts of the Russian dominions, she was cast away on the former island; and of the whole company, consisting of 70 men, only a Portuguese and a Lascar were saved. On Behring's first arrival in this island, it swarmed with black and blue foxes, which never having had to dread the destructive hand of man, were perfectly tame. They ravenously devoured the dead animals thrown ashore by the waves; and the Russians, in contending with them for what was to prove their own subsistence, had sometimes to destroy two or three at once with their knives: before they could inter their deceased companions, also, the hands and feet were often gnawed from the bodies, by these rapacious creatures. Several marine animals frequented the shore, especially the sea otter, whose skin is extremely valuable, and bears a high price in China. Before they had likewise learned to dread their enemies, 900 of their skins were collected, and afterwards turned out a great prize to the Russians. When the sea otter disappears in March, it is replaced by great numbers of the sea lion, and several tribes of phocæ. The sea cow was commonly an object of pursuit, by Russian adventurers to Behring's island; but the race has either been extinguished, or is deterred by danger from approaching the shore, and none have been killed since 1768. Whales are extremely numerous in the surrounding seas: a dead one, cast up, formed for some time the principal article of subsistence of Behring's crew. (c)

BEERING, BEHRING, or BERING'S STRAITS, a celebrated channel 59 or 40 miles in breadth, which separates the two great continents of Asia and America, in North Latitude 65° 50', and East Longitude 191° 50': bounded on the Asiatic side by the projection of East Cape from the country of the Tchutski, and on that of America by Kigmil, or Cape Prince of Wales. A problem had long been agitated among geographers, whether the Asiatic and American continents were united towards the north, or divided by a navigable sea. When Peter the Great of Russia was in Holland, in the year 1717, he was solicited to send an expedition to the northern regions, whereby this point might be determined; and to satisfy the wishes of those interested in discoveries, he acceded to their desire. On returning to Russia, he did not forget his promise, and, with his own hand, framed a set of instructions, which were delivered to Admiral Count Apraxin to be carried into execution. The purport of these was, first, to construct one or two decked vessels in Kamtschatka: Secondly, that the unknown northern coasts should be visited for the purpose of ascertaining, if Asia was joined to America: And, thirdly, that some European port should be gained; and an accurate journal kept of all that occurred, together with a description of the places. But the death of this distinguished potentate interrupted the project.

Meantime, on recurring to earlier periods of history, it seems extremely probable, that the fact had been already ascertained; and that this channel, separating the two continents, had actually been navigated. In 1636, mariners from Siberia began to traverse the Icy Sea, and successively recognised the rivers Alasey, Indigirka, and Kovima, which fall into it. Immediately after discovering the last, they became desirous of extending their discoveries still farther, in the hope of levying tribute from whatever inhabitants might be found; and in 1646, a company of adventurers embarked from the Kovima. Steering to the east, they reached a

bay, where they trafficked with the Tchutski tribe; but not understanding their language, none ventured on shore among them: and content with the success of their voyage, without proceeding further, they returned to the place of their departure. The prospect of a profitable trade, led to a second adventure, on a larger scale, in 1647 or 1648. Seven vessels were equipped, in one of which was Semcon Iwanow sin-Deschnew, a Cossac, to attend to the interests of the crown; and in another, a supercargo on account of the merchants. At that time a numerous people was believed to dwell on the banks of the Anadyr, a river known little more than by name, which was thought to discharge itself into the Icy Sea. The fate of four of the vessels is unknown: that containing Deschnew, arrived at a great point of land, lying east north-east, and turning round towards the river Anadyr; opposite were two islands, on which were men of the Tchutski tribe, remarkable from having the teeth of the sea-horse stuck through their lips. With a fair wind, Deschnew supposed it possible to reach the river Anadyr in three days; nor would the journey by land probably occupy longer, as the river falls into a gulf. In coasting along the point, one of the barks was wrecked; but the crew being saved, were partitioned into the other two; subsequent to which the adventurers had an engagement with the Tchutski. Deschnew soon lost sight of his consort; and, after struggling with tempests, was himself cast away apparently to the south of the Anadyr. He and the survivors of his company underwent great hardships; they wandered long in quest of the river, which, at length having found, they built a pallisadoed habitation, or ostrog, and reconnoitred the surrounding country. Another troop of adventurers, marching overland from the Kovima in search of the Anadyr, with the same view of tribute, joined the party there when least expected, in 1650. From these facts we can entertain little doubt, that what has been judged a discovery of the seventeenth century belongs to that preceding it; and, independent of this relation in particular, added to probable circumstances that Deschnew's consort was wrecked on the coast of Kamtschatka, there are corroborative relations of a subsequent period. It appears, that the Russians and the Cossacs in their service had been oftener than once on Tchutski Noss, or the great promontory opposite to America, across which one party marched, and describe the journey as short; that they were even aware of the islands lying in Behring's Straits, and that the continent lay beyond them to the eastward. All these things have since been proved by the most modern navigators.

Though the proposed voyage of discovery had been interrupted by the death of Peter, the design was speedily revived by the empress Catharine, and its execution entrusted to captain Vitus Behring, a Dane, in the Russian service. He departed from Petersburg along with two lieutenants, Spangberg and Tschirikow in 1725, and wintered at Tobolsk in Siberia, waiting the breaking up of the ice, that he might descend the rivers, and proceed to Kamtschatka. He was unable to reach this country before 1728, when he built a shallop, and furnished it with provisions sufficient to serve forty men during a year. Behring coasted along the north-east of Kamtschatka, framing, at the same time, an accurate chart of his voyage, which is yet esteemed one of the best extant. In latitude $64^{\circ} 30'$, he fell in with a baidar or canoe, carrying eight men of the Tchutski tribe, with whom he spoke, by means of a Koriak interpreter.

VOL. III. PART II.

They came on board to learn what the Russians had in view, and made some communications concerning the direction of the land, speaking of an island also which lay in their route not far from the shore. On the 15th of August, after twenty-six days sail, Behring made a cape in north latitude $67^{\circ} 18'$, beyond which, as the Tchutski had told him, the coast trended to the west. He thence concluded, that he had reached the north east extremity of Asia; that the coast farther on would always trend to the west; and this being the case, there was no connection between the Asiatic and American continents. Believing therefore that he had fulfilled the object of his mission, he addressed the officers and ship's crew, representing, that it was then time to think of their return; should they advance farther north, they might be surrounded by the ice, from which it would be no easy matter to extricate themselves; that the fogs which prevailed in autumn would embarrass them; and even should adverse winds oppose their progress, it was scarce possible to reach Kamtschatka, and to winter in that country would endanger their safety. The force of Behring's reasoning convinced his people, and their course was altered to the south. Nothing remarkable occurred in the voyage, except their meeting with four baidars containing forty Tschutkis, with whom they had an amicable interview, and presents were mutually interchanged. Behring took up his quarters a second time in Kamtschatka, where the natives told him of a land existing farther to the eastward; and he saw pines which did not grow on this territory floating on the waves. He was thence induced to undertake a second voyage when the season admitted; but untoward incidents forced him to abandon it; and after a painful journey overland, and descending rivers on rafts, he reached Petersburg in 1730. We have already seen the disastrous termination of the third voyage, undertaken for more extensive discoveries in 1741, and we hear nothing more of a passage through the Straits until 1764. It is reported, that a mercantile company established at the mouth of the river Kovima, at that time sent out some persons for the purpose of traffic, who doubled Tschutski Noss, (or East Cape) in 74° of north latitude. Sailing to the southward, they passed through a strait to some inhabited islands in 64° north latitude, which they supposed belonged to the continent of America, and traded for beautiful furs with the natives. There is probably an error in the latitude, which is too high, and which would have conducted the navigators to a part of America where no opening is yet known; but they certainly passed Behring's Straits, and they were met by another party on a commercial voyage from Kamtschatka.

In 1778, our celebrated navigator, captain Cook, passed the Straits, endeavouring to get farther to the north; and after his decease, captain Clerk, in the subsequent year, repeated the attempt, in which he was checked by the ice, and forced to return. These navigators bestowed the name on this channel which it now bears, in honour of its reputed discoverer, and settled what had been the subject of so much controversy among geographers respecting the separation of the two continents. Contrary to the opinion generally received, they fixed the longitude of East Cape in $190^{\circ} 22'$, and made the width of the Strait thirteen leagues. East Cape forms a lofty peninsula, connected to the continent by a narrow neck of low land. Great similarity was remarked between the two continents to the northward of the Straits; both

being destitute of wood, the shores low, and mountains to a great height appearing farther up the country. A slight current from the westward ran in the Straits, and the greatest depth of water was between 29 and 30 fathoms.

The late empress Catharine of Russia sent out a secret expedition in 1785, for the purpose, among other things, of ascertaining the situation of the islands between the two continents. The commanding officers were provided with the journals of all former navigators, but the extent of their nautical discoveries seem to have been limited. In August 1790, this expedition reached Behring's Straits; and made some detached observations without passing through them. The distance between the two continents was calculated to be forty-eight miles, which differing from the opinion of captains Cook and Clerk, leaves us in uncertainty with regard to the truth. Possibly the line is taken from the two promontories, one of which lies considerably north of the other.

Three small islands lie in the mid channel of the Straits; the first called Imalin, bearing 26° S. E. 24 miles distant from the eastern promontory; the next, which is the largest, Imaglin, lies six miles further, in a north-east direction; and Okiavaki, the third and smallest, is ten miles distant, south by east. Near the southern entrance of the Straits, King's Island is situated; it is lofty, with a broken and irregular summit.

The discovery of Behring's Straits would have been attended with important consequences, did it not appear that immense fields of ice, never melting in the northern seas, oppose all attempts to navigate the higher latitudes. See Muller, *Voyages et Découvertes faites par les Russes*, tom. i.; Cook's *Third Voyage*; Billings's *Voyage*; Coxe's *Russian Discoveries*. (c)

BEGEMDER, a rich and valuable province in Abyssinia, is bounded on the north by Balyan, a district adjoining to Samen; on the east by Lasta and Angot; on the south by Amhara, which runs parallel to it, and from which it is separated by the river Bashils; and on the west by Dembea. According to Mr Bruce, Begemder is 180 miles in its greatest length, and 60 in breadth; but in this extent he includes Lasta, which belongs more properly to the province of Samen. Begemder abounds in iron mines, and is well stored with beautiful cattle. Its mountains are less steep and rocky than those of the other provinces, (if we except Lasta,) and abound in wild fowl and game. Its inhabitants are esteemed the best soldiers in the empire; but their rudeness and ferocity are proverbial even in Abyssinia. The south end of this province is cut into prodigious gullies, apparently by floods; but of these floods no tradition exists. It forms the great barrier against the encroachments of the Galla, who have often endeavoured in vain to gain a settlement there: whole tribes of them have been cut off in the attempt. Favour alone is necessary to procure the government of many of the provinces in Abyssinia: others are given to poor noblemen to enable them to repair their fortune: but the consequence of Begemder, from its vicinity to the metropolis, is so well understood, that none but noblemen of rank and character, able to maintain a large army, are entrusted with its government. Several small provinces have been dismembered from Begemder, particularly Foggora, reaching from south to north about 35 miles, and about twelve miles from east to west, from the mountains of Begemder to the lake Izana. On the

north of this, are two small governments, Dreda and Karoota, the latter of which, is the only territory in Abyssinia which produces wine. See Bruce's *Travels in Abyssinia*. (μ)

BEGONIA, a genus of plants of the class Monœcia, and order Polyandria. See BOTANY. (w)

BEGUINS. See Mosheim's *Church Hist.* vol. iii. p. 232.

BËHEM, BEHEIM, BOEHME, BEHIN, or BEHINIRA, MARTIN, a navigator and geographer of the fifteenth century, to whom the credit of discovering America has been ascribed, in preference to the claims of Christopher Columbus.

Behem was born at Nuremberg, in Germany, of a noble family, some branches of which are yet extant. From infancy he betrayed a peculiar predilection for the study of astronomy and navigation; and on attaining a maturer age, he began to conceive, that antipodes and a western continent might possibly exist. Nothing could be more favourable for instilling a spirit of enquiry, than his being the pupil of the celebrated John Muller, or Regiomontanus. Records are preserved in the archives of Nuremberg, proving, that, under these impressions, he offered his services for a voyage of discovery, to Isabella, daughter of John I. king of Portugal, and regent of the duchy of Burgundy and Flanders. This princess accordingly provided him with a vessel, in which he traversed the western seas, and in 1460 discovered the island of Fayal; so named from the beech trees, called *faye* in Portuguese, with which it abounded. He next discovered neighbouring islands called by him Azores, from the number of hawks seen on them.

Behem obtained a grant of the island of Fayal from Isabella, and establishing a colony on it, resided there about twenty years, during which time he was occupied in making further discoveries. In 1484, eight years before the enterprises of Christopher Columbus, he solicited John II. king of Portugal, to provide him with the means of undertaking a great expedition to the south-west. This application also proving successful, Behem embarked, and discovered that part of the coast of America now called Brazil, and advancing still more to the southward, reached the straits of Magellan, or the country of some savage tribes, whom he called Patagonians. He is said to have bestowed that appellation upon them, from the extremities of their bodies being covered with skin, bearing greater resemblance to the paws of a bear than to human hands and feet. James Canus, a Portuguese, was associated with Behem in this second voyage, which having occupied above two years, the navigators returned to Portugal after losing many of their men.

If these facts be undoubted, we ought to ascribe the discovery of the American continent and the Straits of Magellan to Martin Behem, instead of Columbus and Magellan. The first did not sail until 1492, and the second not before 1519, a long time after Behem's expedition.

As a reward for the discoveries made by Behem, he was knighted by his patron the king of Portugal; and in an interesting account of the ceremony on the occasion, we are told that the duke of Begia put on his right spur, the count Christopher de Mela his left: his iron

helmet was put on by the count Martini Mabarinis ; and the king himself girded on his sword. This dignity, however, some have supposed, was conferred for the discovery of the kingdom of Congo in Africa, because the gold and precious articles carried from thence to Portugal would make a much greater impression, than merely ascertaining the existence of another continent.

In the year 1492, Behem undertook a journey to his native city Nuremberg. While residing there, he constructed a remarkable terrestrial globe yet in preservation, from the writings of Ptolemy, Strabo, and Pliny, of the ancients, and from the accounts of Marco Polo and Sir John Mandeville, travellers of the thirteenth and fourteenth centuries. The track of the navigator's own discoveries is also laid down, which plainly exhibits, that the western lands marked on the globe, mean the coast of Brazil and straits of Magellan.

After having performed several other interesting voyages, Behem died at Lisbon, in July 1506.

We cannot disguise, that there are historians who have treated the discoveries ascribed to this navigator, as so many fictions of the Germans, arising from their desire of claiming the first voyages to the new continent. Yet it is acknowledged, even by those who most keenly controvert the point, that Behem effected a settlement in Fayal ; that he was the intimate friend of Columbus ; that he framed a chart of the seas before unknown ; and that Magellan possessed a globe constructed by him. All the disputed facts are ably discussed in a memoir by M. Otto, to which we shall refer. *American Philosophical Transactions*, vol. ii. p. 263. (c)

BEHUT, or БѢТУН, the *Hydaspes* of the ancients, is a large river of Hindostan, which issues from the spring of Wair in Cashmere, and runs into the Chunaub, about fifty miles above Moultan. See Robertson's *Disquisition on India*, p. 18 ; and Rennel's *Memoir*, p. 99. (j)

BEJARIA, a genus of plants of the class Dodecandria, and order Monogynia. See BOTANY. (w)

BEING. See METAPHYSICS.

BEIRA, a province of Portugal, divided into the upper and the lower Beira. It is bounded on the north, by the river Douro, which separates it from the provinces of Entre Douro a Minho, and Tralos Montes. The ocean and part of Estremadura limit it on the west ; the Tagus and another part of Estremadura limit it on the south ; and it is enclosed on the east by the kingdom of Leon and Spanish Estremadura. This large and fertile province is about thirty-four miles long and as many broad, and contains the cities and towns of Coimbra, Lamego, Guarda, Viseu, Miranda do Corvo, Aveiro or Nova Braganza, Tentugal, Ovar, Pinhel, Almeida, Francoso, Meda, Castello Branco, Penamacor, and Covillha. The river Mondego, which traverses the greater part of the province, runs into the sea near the southern extremity, and adorns in its course many beautiful and fertile valleys. The narrow and rich vale of the Mondego, in the neighbourhood of Coimbra, is reckoned one of the most enchanting spots of Portugal, and has been celebrated in the immortal strains of Camoens.

"In sweet Mondego's ever verdant bowers,"

lies the scene of the interesting and tragical story of Inez de Castro.

The country round Coimbra is remarkable for its beauty and its cultivation. The mountains are covered with pines, and even German oaks. They consist partly

of a coarse grained sandstone, alternating with a grey limestone. High schistus mountains began at a distance. A yellowish grey argillaceous slate changes to a sand slate, which is succeeded by mica slate, terminating in granite. The plants in this part are remarkably beautiful, the land is well cultivated, and oil is produced in great abundance. The olive tree abounds so much, that the traveller may wander for whole days without observing any other tree. The olives are ripe in December and January. They are beaten from the trees by means of long poles. The oil presses are wrought by oxen ; but the oil is much deteriorated by want of cleanliness in the process. The ripe brown olives are the only ones that are pickled by the Portuguese.

Various kinds of wheat grow round Coimbra ; but the summer wheat only succeeds, when the inundations of the Mondego have rotted the seed in the ground. Barley and a little rye are also sown ; and rice grows in the marshes along the Mondego. Indian corn is produced in much larger quantities throughout Beira, than in the southern provinces, where the soil is too light and dry. The oranges of this province are excellent, and are exported to other countries. Coal is found along the coast, from Buarcos to Figueira ; but in 1779 this valuable mineral had not been worked.

Mountains of argillaceous schistus begin near Sobral, not far from Ovar ; mica slate soon succeeds it, and introduces a lofty ridge of steep mountains crowded upon one another, and extending along the southern banks of the Douro, even farther than Lamego.

This province is divided into seven corregidors and two oydors, viz.

	Population.
Corregidor of Coimbra,	150,000
Town of Coimbra,	12,000
Corregidor of Viseu,	95,000
Corregidor of Lamego,	60,000
Corregidor of Pinhel,	70,000
Corregidor of Guarda,	7,000
Town of Guarda,	1,000
Corregidor of Castello Branco,	40,000
Town of Castello Branco,	4,000
Oyder of Montemor-o-Velho,	3,000
Oyder of Mon-feira,	40,000
Town of Mon-feira,	4,000
The whole population of Beira amounts to 560,000.	

(q)

BEIT EL FAKIH, or *The Dwelling of the Sage*, is a city of Arabia, in the province of Yemen, situated in a well cultivated plain, about 24 miles from the Arabian Gulf. The tomb of Ahmed iba Musa, situated on a sandy hill near the town, attracted the inhabitants of Ghalefka, when their harbour was choked up with sand, to settle in the vicinity of that consecrated spot. As the new city increased in magnitude, a citadel was built for its protection. The town is composed of a number of houses, or rather huts, detached from one another ; and after it was burned down in 1765, many edifices of stone were erected. The mode of building is constantly improving ; yet a great many of the houses are built with mud mixed with dung, and the roof is thatched with a kind of grass common in the country. These houses are not divided into separate apartments. A range of straw beds surrounds the apartment ; and it is not often that they have any windows. A species of ant, called *ard* by the Arabs, infest the houses to a very great degree. By

forming covert ways, they introduce themselves into the houses, and destroy both clothes and provisions. The trees in the garden suffer also from their depredations; and even when their cells and passages are destroyed, they repair them with astonishing celerity.

"This city," says Niebuhr, "is in a favourable situation for trade, being only half a day's journey from the hills on which the coffee grows, and but a few day's journey from the harbours of Lobeia, Hodeida, and Mocha, from which this commodity is exported; it naturally becomes the most considerable market for it. This trade brings hither merchants from Egypt, Syria, Barbary, Persia, Habbesch, India, and often from Europe." A dola, who resides in this town, has an extensive jurisdiction over the surrounding country. According to Lord Valentia's chart of the Red Sea, Beit el Fakih is situated in East Long. $43^{\circ} 23' 40''$, and North Lat. $14^{\circ} 32' 10''$. See Niebuhr's *Travels*, Sect. viii. chap. vi. (q)

BEKAA, the name of a fertile valley in Syria, which lies between the mountains of Antelibanus and Libanus. The earthquake of 1759, destroyed the thriving villages and plantations of the Moloualis; and the subsequent cruelties of the Turks completed the desolation of this charming valley. (j)

BEKIA, BEKOYA, BEQUIA, or BOQUIO, called by the French *Little Martinico*, is the smallest of the Grenadilles islands in the West Indies. It is about 36 miles in circuit, contains 3700 acres, and produces wild cotton and water melons. The inhabitants of Grenada and St Vincent's resort to it for the purpose of catching turtles. It is 52 miles north-east of Grenada. West Long. $61^{\circ} 22'$, North Lat. $12^{\circ} 37'$. (j)

BELEM, a town of Portugal, in the vicinity of Lisbon, and province of Estremadura, is situated on the north bank of the Tagus, and is remarkable for its monastery and royal palace, and as the burial place of many of the Portuguese kings and princes. A little below Belem is a square tower, defended by cannon, along with several batteries, and a small irregular fort. The magnificent church of Belem sunk in 1756. Mr. Link observes, that this town, which partly stands on a basalt hill, suffered less from the earthquake of 1755, than some parts of the town evidently founded on limestone. Hence he suggests, that the basalt had, at some former period, been forced up from these parts by a similar convulsion; and that the shocks which Lisbon has occasionally felt, are attempts of nature to raise similar hills.

The monastery which we have mentioned, is one of Hieronymites, the architecture of which is very striking, the greatest pains having been taken to avoid every appearance of regularity and order. The adjacent church is in a grand stile of Gothic architecture; and there are also in Belem two handsome churches, which have been recently erected. Near one of these churches is the botanic garden; and the royal garden is a little farther on. Belem is a considerable market town, and is inhabited by many persons of property, and by tradesmen of the highest class. The royal family formerly had their residence here, but after the castle was burnt, they removed to Quelus. (q)

BELEMNITE. See ORYCTOGNOSY.

BELFAST, a large flourishing town of Ireland, in the county of Antrim, and capital of the province of Ulster, situated at the mouth of the river Lagan, which separates it from the county of Down. The lower part of the town is not elevated more than six feet above high water mark at spring tides. Belfast lough, or the bay

of Carrickfergus, which receives the river Lagan, is a spacious estuary, containing twenty-four square miles, a great part of which is left dry every tide, which is the case likewise with Strangford lough, another great estuary, the nearest extremity of which is eight miles S. E.

Between Belfast and Lough Neagh, which is about twelve miles west of it, there is a chain of mountains, the highest of which, called Devis, is about 1580 feet high. These mountains extend to the neighbourhood of the town, and are mostly covered with heath. Some of them, however, consist of very good loam to their summits, interspersed with veins of limestone. About three miles north of the town stands the Cave Hill, so called from a number of caves in it formed out of the solid rock, the largest of which is about thirty-two feet wide, and thirty-six long; this hill shelters the bay on the west, and being contrasted with the delightful plantations and elegant country seats which extend almost from its base to the town, exhibits a most beautiful and picturesque view. The town is more ancient than is generally supposed; the parish is a vicarage, called *Shankil*, or the old church. There was formerly a castle at Belfast, the ruins of which are still to be seen. Its date is unknown; but it is said to be very ancient, and seems to have been a post of some importance, as it was twice taken and destroyed by the Earl of Kildare, lord deputy, in 1503 and 1512. It was inhabited before Queen Elizabeth's time, by Randolphus Lane, and granted by her, with a vast tract of adjoining lands, to the family of Smith, who forfeited their title in the reign of James I.

About the beginning of the seventeenth century, after the complete reduction of Ireland, Belfast became the property of Sir Arthur Chichester, afterwards lord deputy and baron of Belfast, who exerted himself in the settlement of Ulster, and in whose family it still remains. Through his influence it was made a borough in 1613, and sent two members to the Irish Parliament, and under the act of union returns one member to the Imperial legislature. An English gentleman, who travelled through part of Ireland in 1635, and whose journal is in the possession of General Vallancey, mentions, that Lord Chichester had a stately palace at Belfast, which was the glory and beauty of the town, and which was his chief residence. Through the interest of this nobleman, also, the custom-house was removed from Carrickfergus to Belfast by the Earl of Stafford in 1638, for which a compensation of 2000*l.* was paid to the corporation of Carrickfergus. In 1648, Belfast was taken possession of by Colonel (afterwards the famous General) Monk, for the Parliament of England; yet, so late as 1726, it appears to have been a small place of little consequence. But situated in the centre of two populous, industrious, and intelligent counties, it is now become one of the most interesting objects in Ireland to the political economist. Its inhabitants are celebrated for their hospitality, taste, and public spirit; and its merchants have extended their commerce to every part of the trading world, except where exclusive privileges to chartered bodies mark the bounds of their extension.

The town is well built, mostly of brick, and the streets are broad, straight, and well lighted. The bridge over the Lagan is about 2560 feet long, with twenty-one arches, eighteen of which are in Down, and three in Antrim; the channel dividing the two counties running under the third arch. It was built about the time of the Revolution at the joint expense of both counties, and cost 12,000*l.* With regard to size, Belfast is generally

reckoned the fourth, and with respect to commerce it is the third, town in Ireland, being next to Dublin and Cork. Vessels of 200 tons, half-loaded, used to come up to the quay, there being about ten feet water at spring tides; but now the water is from nine to thirteen feet deep, according to the time of the moon, having been deepened by the exertions of the ballast corporation. Convenient docks have also been lately erected for building and repairing vessels. Those vessels that cannot come to the quays, lie at *Carmoil* pool, (the place of heaps of fish,) about three miles from the town, where there is secure anchorage for large ships. The West Indian and American trade, before the late restrictions on commerce, was very considerable. Their chief exports are linen, butter, beef, pork, oatmeal, &c. The value of Irish goods exported from Belfast during the year 1809 amounted to 1,910,909*l.* 5*s.*, of which linen formed the greatest part. In 1775, the gross customs amounted, according to Mr Young, only to 64,800*l.*, including the excise on tobacco and foreign spirits; but ever since it has gradually increased, except during the year 1798, and in the year ending the 10th October 1809, amounted to 377,439*l.* 16*s.* 11½*d.* The excise of Belfast in 1796 was 9097*l.* 13*s.* 2½*d.*; but previous to the stoppage on distilleries, it had risen to 22,165*l.* 5*s.* 6*d.*, exclusive of Carrickfergus and Templepatrick, which walks are included in the same district. The duty on licences, in 1801, amounted to 4309*l.* Though the increase, as in other places, must be partly attributed to the increase of duties, yet the extent of trade must also have been considerable. The population in 1782 was about 13,105: At present (1810), it is estimated at 30,000, including Ballymacarret, the suburbs on the Down side of the Lagan. There were, in 1791, 695 looms, the greatest part of which were employed in the linen and cotton manufacture. There are also manufactories of glass, sugar, earthen ware, &c. The public buildings are not many. The white linen hall is large and commodious; and the exchange, over which there is a good assembly room, is a handsome building, situated near the middle of the town. The foundation was laid in 1769: It was erected at the expence of the late Marquis of Donegall, and cost 4000*l.* There is a barrack, healthfully situated, which contains about 800 men; and near it has been lately erected an artillery barrack. The houses of public worship are ten; an established church in Donegall street, a handsome structure, but rather small for the parish; six dissenting meeting-houses, four of which are presbyterian; a quaker meeting-house; a methodist meeting-house; and a Roman catholic chapel. There are many charitable institutions; the principal of which is called *The Belfast Incorporate Charitable Society*, or poor-house and infirmary, which was built by subscription and lotteries. The foundation was laid in 1771: It cost about 7000*l.* and was incorporated by act of Parliament in 1774. It is a large commodious building, healthfully situated, in which about 300 of various ages are maintained and clothed, and the young educated. There are also a lying-in hospital, a fever hospital, a dispensary, a charity school for boarding girls, a day school for boys and girls, a Sunday school of great utility, and a school of industry for the blind; none of them very extensive, but sufficiently so for such an industrious country. In the beginning of 1809, a house of industry was established, similar to the Hamburgh plan described by Mr Voght, for the purpose of abolishing mendicity, and assisting

the industrious poor, which promises to be of incalculable benefit to the town. In such a place as Belfast, many commercial institutions might be expected; and, accordingly, we find a chamber of commerce, a ballast office corporation, two insurance offices, a police committee, &c. &c. There is also a book society, called *The Belfast Society for promoting Knowledge*, which possesses about 2000 volumes, a cabinet of minerals, and several philosophical instruments. There is another book society, under the title of *The Belfast Society for acquiring Knowledge*, nearly as extensive as the former. A *Literary Society* has also been lately established, whose chief object is polite literature, science, and antiquities, *fasciculi* of which are occasionally published. There are a great many other societies similar to the above, but they are too numerous to be mentioned. An academy, for the education of the higher class in this town, was founded by the inhabitants in 1786, and has been hitherto under the directions of a presbyterian minister; but the advantages of it are not confined to any sect. In 1807, another academy was opened, which is under the direction, also, of one of the presbyterian ministers, and is well attended. The private schools are innumerable. But that which most entitles the inhabitants of Belfast to the gratitude of their countrymen is the *Academical Institution*, or *New College*, the foundation stone of which was laid in July 1810. A subscription was opened in 1808, for the purpose of establishing a college on the following extensive plan: Large schools are to be built and endowed for educating boys for every department of life; and professorships are to be founded in the following branches, viz. mathematics, natural philosophy, logic, metaphysics, moral philosophy, belles lettres, chemistry, botany, and agriculture. A subscription of five guineas makes a proprietor; twenty guineas qualifies one for holding the office of manager; fifty for that of vice-president. That of president continues for life, and has been vested in the Most Noble the Marquis of Donegall. The fund for carrying this undertaking into effect, already amounts to 16,000*l.* which was solely collected by private subscription, and the sum is daily increasing. The proprietors have obtained a charter of incorporation, and the building is advancing with rapidity.

The proprietor of the soil is the Marquis of Donegall, a most indulgent landlord, and highly respected by his tenantry.

Belfast is situated 80 miles north of Dublin, in West Long. 5° 49', and North Lat. 54° 43'. Variation of the needle in 1810, 28° 30' west. See Arthur Young's *Tour*; Dr Beaufort's *Memoir*; *Belfast Monthly Magazine*, &c. (g)

BELGÆ, a people of ancient Gaul, who inhabited the tract of country extending from the Rhine to the Loire. They seem to have been originally Goths or Scythians, who after defeating the Cimbri, took possession of the north-west of Gaul. See Cæsar's *Comment. De Bell. Gall.* lib. i. and ii.; and Henry's *Hist. of Britain*, vol. i. p. 246. (j)

BELGRADE, the *Alba Græcorum* of the ancients, is the capital of Servia in Turkey, and is situated on the declivity of a hill, at the junction of the Save with the Danube. The streets of Belgrade are covered with wood, to shelter the inhabitants when engaged in their mercantile concerns, as they never enter the shops to purchase, but receive the commodities out of the window. The only public buildings of any importance are the ca-

ravansera or public inn, the college, two exchanges, and two bazars, or bezestins, built in the form of a cathedral church, where the finest articles of merchandise are exposed to sale. The aqueducts, about 6 miles from Belgrade, were built by Valentinian I. for conveying water to Constantinople. They were afterwards repaired by Solyman the Magnificent, who, in order to have them kept in repair by the inhabitants of twelve Greek villages in their vicinity, exempted them from the usual tribute. The principal of these aqueducts are three large buildings erected over three vallies. The longest of them has many arches, but they are less in magnitude than those of the other two, which consist of two rows of arches one above the other, and appear to be of more ancient architecture. The largest of these two is composed of four large arches, each 60 feet long, and about 6½ high, supported by octagonal pillars, about 168 feet in circumference near their base. The aqueduct which appears more recent than the rest was probably built by Solyman.

The position of Belgrade upon the Danube renders it peculiarly fitted for commerce, and gives it an easy communication with Vienna and the Black Sea. It is resorted to by Austrian, Venetian, Armenian, Turkish, Jewish, Hungarian, Greek, and Sclayonian merchants; and the Armenians and Jews are employed as factors. For *Ragusians* and drabs, the Belgrade merchants give in exchange wax and quicksilver, which they receive from Upper Hungary and Transylvania. The duty annually levied upon goods amounts to 400,000 livres. The surrounding country, which is very poorly cultivated, produces fine oaks, and is marked with several small villages inhabited by Greeks.

The situation of Belgrade, as the key of Hungary, has frequently rendered it the object of fierce contention between the Austrians and the Turks. In 1456, Belgrade was besieged by Amurath; but the garrison of 10,000 by which it was defended, compelled the Turkish army to retire. Solyman the Magnificent made himself master of it in 1521; but it was recovered in 1688 by the imperial army under the Elector of Bavaria. The cruelties of the governor to the captain of the Greek interpreter, whom the Elector had charged with the summons for a surrender, inspired the besiegers with a thirst for vengeance, which was most wantonly gratified in the murder of the defenceless inhabitants. The Turks again laid siege to it in 1690; and, in consequence of a bomb having lighted upon the great tower, by which the walls of the city were thrown down, and 1200 of the garrison destroyed, the Austrians were compelled to resign the city to the fury and cruelties of the besiegers. The Austrians, in 1693, attempted to regain possession of this important place; but after many fruitless attempts, and the loss of 1000 men, they were under the necessity of raising the siege. The possession of Belgrade was confirmed to the Turks by the treaty of Carlowitz in 1699, and they remained masters of it till the year 1717, when it underwent one of the most celebrated sieges that history has to record.

Under the pretence that the Venetians had infringed the treaty of Carlowitz, the Turks declared war against Austria in 1715. In May 1717, Prince Eugene marched to the siege of Belgrade with a fine army of about 90,000 men. On the 15th of June, he effected the passage of the Danube in boats, and Belgrade was completely invested on the 19th of that month. The Turkish garrison amounted to about 25,000 men, and were as-

sisted by a strong flotilla on the Danube. The besiegers were harassed by a violent storm on the 13th of July, which broke down their bridges over the Danube and the Save, and by several bold sorties, in which the Turks displayed the most undaunted courage; but a complete chain of works having been constructed, the Austrians were completely secured against the efforts both of the garrison and the elements.

The Austrian batteries were opened with tremendous effect on the 23d of July. The part of the town near the river was a heap of ruins; and nothing but the hopes of succour, and confidence in the strength of their fortifications, could have prevented the garrison from yielding to the enemy. On the 31st of July, a Turkish army of 200,000 men, under the Grand Vizier, arrived at Belgrade, and encamped above the Austrian camp, having its left towards the Save, and its right supported by the Danube. The works which the Grand Vizier threw up, were mounted with 140 pieces of cannon. Being thus placed between the fire of the Ottoman army and that of the garrison, while his army was wasting with the dysentery, and a mortality prevailing among the horses, the situation of Prince Eugene rendered it necessary to hazard some desperate enterprise. It was accordingly resolved, in a council of war, to make a furious attack upon the Turkish camp; and at one o'clock in the morning of the 16th August, the Austrian army quitted their trenches amid the obscurity of a thick fog. While employed in their preparatory movements, the fog had thickened to such a degree, that the Austrian right wing, under Count Palfi, missed the redoubt at which they were to form, and unwillingly surprised one of the advanced works of the enemy. The troops of the grand vizier, roused by this sudden alarm, rushed to the combat. The right being thus engaged, inclined too much to its right flank, and left a considerable vacancy in the centre. Prince Eugene, who commanded the left wing, perceiving that the right was engaged, was forced to the attack before his battalions had time to form. The awful uncertainty which the mist occasioned, hurried some of the Austrian detachments into the midst of the enemy, where they were instantly cut to pieces. The combatants were completely hid from each other, till they arrived at the points of each others bayonets, and at this fatal instant, the reserved and well-directed fire of the Austrians produced a dreadful carnage among their enemies. The centre of the Ottoman army having no foes to oppose, separated the two wings of the Austrians, and opened a deadly fire upon their antagonists; and they would have infallibly put an end to the combat, had not the fog dispersed at this critical moment, and discovered to prince Eugene the perilous condition of his army. Eighteen battalions of his second line of infantry, under the prince of Bevern, were instantly hurried against the Turkish centre. Every soldier seemed to feel, that on his single arm depended the fate of the day; and with an intrepidity and valour which could scarcely be surpassed, the Turkish battalions were broken as they advanced, and pursued to their very trenches, over the mangled bodies of their comrades. The vacancy in the imperial centre being now filled up, the two wings were formed for a new attempt. The battle now became general, and after various success, in which the Turks had sometimes the advantage, the Austrians succeeded in forcing the entrenchments of the enemy, and in driving them from all the redoubts by which their camp was defended.

The imperialists pursued them about three miles beyond the eminence, and permitted them to fly in every direction. In this celebrated action the Turks had 13,000 killed, 5000 wounded, and 3000 prisoners, while the Austrians had only 5000 killed, and 4500 wounded. The result of this victory was the surrender of Belgrade on the 19th, in consequence of a mutiny in the garrison. In 1739, the Turks attempted in vain to retake this fortress, which afterwards came into their possession by the treaty of 1739, alter its fortifications were demolished. In 1789 it was again taken by the Austrians under Marshal Laudohn, who restored it to the Turks at the peace of Sistova, in 1791, since which time it has remained in their possession. BELIDOR, BERNARD FOREST DE, a celebrated engineer in the French service, was born in the province of Catalonia in Spain in the year 1698. While he filled the offices of professor at the new school of artillery of La Fere, and of provincial commissary of artillery, he discovered that too great a quantity of gunpowder was used in the loading of cannon, and that the same effect might be produced by two thirds of the quantity. Belidor had, unfortunately for himself, communicated this discovery to Cardinal Fleury without consulting the grand master of artillery, who was so irritated as to deprive Belidor of both his situations. Being thus left at liberty he accompanied the Prince of Conti to Italy; and on his return to Paris, he was again brought into notice at court. On the 31st March 1756, he was received as a supernumerary associate of the Academy of Sciences; and Marshal Belleisle promoted him to the office of inspector of artillery, and gave him apartments in the arsenal of Paris, where he died on the 8th of September 1761, in the sixty-third year of his age. The works of Belidor are, *Sommaire d'un Cours d'Architecture Militaire, Civile et Hydraulique*, 12mo, 1720. *Nouveau Cours de Mathematiques*, 4to, 1725. *La Science des Ingenieurs*, 4to, 1729. *Le Bombardier Francoise*, 4to, 1739. *Architecture Hydraulique*, 4 vols. 4to, 1737; a work containing much new and practical knowledge on the various subjects of which it treats. *Dictionnaire portatif de L'Ingenieur*, 8vo; and *Traité des Fortifications*, 4 vols. 4to. Besides these works, he published several pieces in the *Memoirs of the Academy of Paris* for 1737, 1750, 1753; and 1756, and a paper on Gunpowder in the *Memoirs of the Academy of Berlin* for 1734, tom. iv. p. 116. (π)

BELISARIUS, supposed to have been born and educated in Thrace, was first one of the private guards, and afterwards the chief commander of the armies of Justinian. He was first entrusted with the command of a body of troops on the Persian frontiers; and about four years afterwards, was appointed general of the East, in the war against Cosroes king of Persia. Returning from this war in 530, in which he had acquired great renown, he came very seasonably to the relief of the emperor, who was hard pressed by a formidable insurrection at Constantinople; and, immediately falling with his victorious troops upon the insurgents, put to death an incredible number of them, (according to some authors 50,000.) and completely restored the peace of the metropolis. In 532, he was sent to conduct the war against the Vandals in Africa, which, in little more than the space of one year, he brought to a successful termination. Returning to Constantinople in 534, with

the Vandal prince Gilimer among his captives, he received the honour of a splendid triumph in reward of his services, and was created sole consul for the year following. He was next employed against the Ostrogoths in Italy in 535; landed first in Sicily, which he speedily reduced; passed over to the continent, and took the city of Naples by storm; received the submission of the Gothic prince Theodatus in Rome; drove back a powerful army of Goths, who under the command of their new king Vitiges, attempted to recover their capital; and completely reduced the remains of their power by taking the city of Ravenna in 539. During the whole of this war, his army never amounted to 20,000, and seldom to more than 10,000 or 12,000 men; but by his determined courage and consummate skill, he rendered this little band victorious over a brave and numerous people. The Goths themselves, admiring the virtues and talents of their conqueror, entreated him to desert his master, and to become their king; but he made use of their proposal only to hasten their subjection, and remained faithful to his sovereign. Neither his eminent services, however, nor unshaken fidelity, could preserve him from the venomous shafts of envy, and the base suspicions of jealousy. Justinian, influenced by the representations of his enemies, but pretending, that he required his assistance against the Persians, recalled him from his command, received him with coldness, and refused him a triumph. But his actions were too conspicuous for their merit to be obscured; and the ingratitude of the emperor served only to increase the admiration of the people. The glory of Belisarius was now at its height; and he was confessedly the first subject in the empire of the East. He had returned to Constantinople crowned with victories, loaded with treasures, surrounded by captive princes; and his fellow citizens were neither insensible to his merits, nor parsimonious of their applause. Whenever he appeared in public, his lofty stature and majestic countenance attracted the notice and respect of every spectator; while his easy access and gracious demeanour engaged the esteem and affection of his countrymen. Seven thousand horsemen, of the most distinguished valour and manly forms, maintained at his own expense, and who had eminently contributed to his conquests by their prowess in the field, now supported the splendour of his name, by their faithful attachment and constant attendance upon his person. Thus honoured by the soldiery, and beloved by the people, Belisarius departed from Constantinople in the year 541, to take the command in Persia; and, having soon restored the sinking state of affairs in that quarter, was beginning to add fresh laurels to his fame, when his career of glory was arrested by the infuriated intrigues of a licentious female. The conqueror of the Goths and Vandals was the slave of his wife Antonina, a woman originally of the lowest extraction and most worthless character; but whose fatal influence over her husband, and whose favour with the Empress Theodora, rendered her the arbitress of his fortune. Belisarius, at length made acquainted with her secret amours, of which he alone had never entertained the smallest suspicion, had charged her with her infidelity, and left her behind him in the metropolis. In consequence of her powerful machinations, he was recalled in disgrace, insulted upon his arrival even by the attendants of the court, deprived of his honours, condemned to a state of privacy, and placed even in momentary expectation of receiving the mandate of his execution. In this reverse

of fortune the renowned Belisarius conducted himself with the most unbecoming pusillanimity; and having been at length relieved from his abject state of terror, by a letter from the empress, announcing his restoration to favour, representing Antonina as his generous intercessor, and recommending her as worthy of his most respectful treatment, he threw himself at the feet of the infamous partner of his bed, acknowledged her as his honoured protectress, and vowed to conduct himself thenceforth as the most submissive of her servants. Thus reinstated in his rank and possessions, he was again chosen to oppose the Goths in Italy, who had now become more formidable than ever, under the conduct of the celebrated Totila. Though he was now better acquainted with the scene of action, and directed his movements with greater skill, than in his former expedition to that country; yet he made little progress against the enemy, and gained no great additions to his military fame. His want of success may justly be attributed to the insufficiency of the reinforcements with which he was supplied; and to the effects of his recent disgrace, which had rendered him more timid in his measures, as well as more distrustful of his soldiers. At length in 548, by the influence of Antonina, he procured permission to return to Constantinople; where, about ten years afterwards, his military talents were again called into notice by a sudden incursion of the Bulgarians, who had rapidly advanced to the walls of the capital. Though weakened by age, and scarcely able to hold a shield, the veteran general readily obeyed the demand for his services, put himself at the head of a tumultuary band, arrested the progress of the enemy, and delivered the metropolis from its alarm. This was the last exploit of Belisarius; and it was not more gratefully requited than any of the former. Through the increasing jealousy of the emperor, he was suspected of a conspiracy, hastily condemned, and put under a guard of soldiers in his own house. His innocence, indeed, was speedily acknowledged, his freedom, possessions, and honours restored; but, within a few months after this acquittal, his misfortunes were terminated by death in the year 565. That he was deprived of his sight, and reduced to beg his bread in the streets of Constantinople, is a fiction of later times, which originated in a poem of John Tzetzes, a monk, who wrote in the 12th century. Making every allowance for the partialities of Procopius, who was the witness and historian of many of the actions of Belisarius, he must be admitted to have been one of the greatest commanders, who had appeared in the Roman empire for many years. He was prudent without fear, bold without rashness, and remarkably fertile in expedients; liberal to his soldiers, humanely attentive to their comfort when sick or wounded, and, at the same time, careful to preserve them under the most rigid discipline. During the march of his armies, the husbandmen enjoyed the utmost peace and protection; so that not an apple was gathered from a tree, nor was a path to be traced in the fields of corn. He was equally careful to preserve the vanquished from the fury of his troops, in the moment of victory; and when they entered the city of Naples by assault, he was seen standing in the streets, repeatedly exclaiming to his soldiers, "the gold and silver are the just rewards of your valour; but spare the inhabitants: they are Christians; they are supplicants; they are now your fellow subjects." He was humble in prosperity; and so exemplary for temperance in his

personal conduct, that, amidst all his successes, and with all the licence of a military life, he was never intoxicated with wine, nor suspected of unchastity. See Gibbon's *Hist. of the Rom. Empire*, vol. iv. 4to, p. 127, 182.; *Ancient Un. Hist.* vol. xvi. and xix.; *Mod. Un. Hist.* vol. xiv.; and Denina, *Delle Rivoluzioni d'Italia.* (g)

BELL. If any definition be required of what is so well known, and in such general use as a bell, it may be "an inverted vase, which, struck with a clapper, is employed singly as a signal, and when combined, either in churches or as a musical instrument."

The size, weight, and figure of bells are arbitrary; but a large bell is usually one-fifteenth of its diameter in thickness, and twelve times its thickness in height. The shape of bells is different in different countries, being more cylindrical or conical in one than in another; and having evidently originated in cymbals or basons, it is probable that from remote ages to the present times, there may have been a gradual progression from a flat circular plate to a figure nearly approaching a cylinder. The gravity and acuteness of tone are, perhaps, regulated by the same conditions affecting the sound of tubular wind instruments; for we know that the greater the capacity, the deeper or more grave is the sound. Thus we learn, that a bell of large dimensions in Moscow yields a grand and solemn tone; and when rung, a deep, hollow murmur, resembling the lowest notes of a vast organ, or the rolling of distant thunder, vibrates all over the city.

The substance of which bells are made, likewise, produces a difference in the tone. Glass is one of the most sonorous bodies, and is formed into bells, though not *ad pulsationem*; we have heard also of wooden bells in the East; but throughout Europe they are invariably made of a compound of copper and tin, called bell metal; to which silver is occasionally added. All metals are more or less sonorous according to figure; even lead, which in most forms is mute, rings loudly in the segment of a sphere: and so favourable is this shape to sound, that it is maintained, had our ancestors been acquainted with the fact, all our bells, instead of being hollow vases inverted, would have been so many segments of metallic spheres. The vibration of every metallic plate is analogous to that of a bell, and if sufficiently ductile, may be moulded into one by simple pressure: thus the imperceptible transition from cymbals to bells is at once evident, and easily accounts for that variety of form to be seen in different countries.

With regard to the tone produced by one kind of metal compared with another, Mersenne, a very intelligent author on the subject, affirms it to be as follows:

Metals.	Weight in air.	Weight in water.	Sound.
Lead . . .	2oz. 28½ grains	1¾ oz. 1sc. 4 gr.	194
Bismuth . .	1½ oz. 34 gr.	1 oz. 1sc. 31 gr.	213
Common Tin	1½ oz. 25½ gr.	1 oz. 1sc. 6 gr.	253
Pure Silver .	1¼ oz. 31 gr.	1 oz. 2sc. 31 gr.	256
Pure Tin . .	1oz. 1½ sc. 30gr.	1 oz. 1½ sc. 6 gr.	263
Common Silv.	1½ oz. 1sc. 24gr.	1½ oz.	266
Bell Metal .	1¼ oz. 1sc. 1gr.	1 oz. 1½ sc. 4 gr.	269
Regulus Stibii	1 oz.	½ oz. 3sc.	270
Pure Copper	1 oz. 6sc. 45 gr.	1 oz. 41 gr.	282
Mixed Copper	1½ oz. ½ sc. 17gr.	1 oz. ½ sc. 4 gr.	285
Brass . . .	¾ oz. ½ sc. 9½ gr.	1½ oz. 70 gr.	294
Common Gold	2 oz. 27½ gr.	1oz. 7sc. 50¾ gr.	294

The figure of the bells with which this experiment was made, approached to that of a large hollow segment of a sphere, being sixteen lines of internal and fifteen lines of external diameter; and being one line and a quarter thick in the lip. Each bell resembled another as much as possibly could be effected in the fabrication, and their specific gravity also afforded an approximation towards more accurate results. The figures represent the tones, the greater number being the more acute, and the smaller the more grave. Thus it appears, that lead is the most grave, and that brass and gold produce an equal tone or unison. Expressing this in musical notes, the tone of a brazen or golden bell forms the sharp seventh above that of a leaden one. It is not evident that the Europeans are acquainted with the most sonorous composition for bells: one known by the Chinese, which we find in their gongs, infinitely surpasses it. The same nation has musical instruments composed of metallic plates extremely sonorous. In ancient history we read, that Charlemagne, while expressing his admiration of the tone of a bell made by an eminent artist, was addressed by the artist himself, soliciting a quantity of pure copper, and requesting that, instead of tin, he should be provided with at least an hundred weight of silver: With these materials, he engaged to cast such a bell, that the one which the emperor admired should seem mute in comparison with the other.

Bells, both ancient and modern, have been applied to purposes sacred, superstitious, or profane. They are undoubtedly of very great antiquity, being frequently mentioned in sacred writ; and, in particular, Moses ordained the under part of the blue tunic of the high priest, worn at religious ceremonies, to be adorned with pomegranates and gold bells intermixed. Commentators suppose that it was for the purpose of announcing his presence, or that he was entering the sanctuary. Nevertheless, there is much controversy concerning the bells, or *tintinnabuli*, of old; and many are induced to suppose, that in general cymbals should be understood. Neither is it agreed what are the names by which the ancients signify bells: but by both ancients and moderns it appears that they were called *Tintinnabulum*, *Petasus*, *Codon*, *Nola*, *Lebes*, *Æs*, *Æramentum*, *Squilla*, *Crotalum*, *Signum*, *Cloca*, *Campana*. All these received their names, either from the place where they were invented, or from their shape, or properties; and it seems generally admitted, that *tintinnabulum*, among the ancients, signifies a bell similar to those we now use; while *campana* is a name belonging to the middle ages.

The Greeks were acquainted with bells: At Athens the priest of Proserpine rung a bell to call the people to sacrifice; and those who went the nightly rounds in camps, rung a little bell at the post of each centinel, to keep him awake. We learn from Strabo also, that in the Greek islands a bell was used to announce the sale of provisions. By the Romans, bells were employed for various purposes, and those somewhat similar to our own. They warned the citizens of Rome that the baths, which there were great and splendid edifices, were ready for use: as, according to the regulations, they were open only at certain hours. Thus Martial, in signifying that a hand bell might be an acceptable present, composes these verses in lieu of it.

VOL. III. PART II.

TINTINNABULUM

Redde Pilam: sonat æs thermarum: ludere pergis?
Virgine vis sola lotus abire domum.

APOPHORETA, 163.

They were hung at the gates of temples, as we learn from Suetonius in the life of Augustus, *Cum dedicatam in Capitolio ædem Tonanti Jovi, assidue frequentaret, somniavit queri Capitolinum Jovem cultores sibi abduci seque respondisse Tonantem pro junitore ei appositum: ideoque mox tintinnabulis fastigium ædis redimivit quod ea fere januis dependebant*: and Dio, speaking of the same fact, says, *Augustus orto die tintinnabulum Jovi Tonanti aspendit: his enim tintinnabulis Bannitores nocturni utuntur, ut si quid usus sit significare possint*. They were used in the houses of the great, and also in the superstitions of the people.

It is uncertain when bells were first introduced into the Christian church for sacred purposes, or for congregating the flock to divine worship. The signal for the hour of performing the latter was in the Eastern churches anciently made by a rattle, or beating on wooden boards with a hammer, which was long retained. Jacobus de Vitriaco, alluding to the Greek church, proceeds, *unde cum omnes alii orientales prelati exceptis, duntaxat, Latinis annulis et mitris pontificalibus non utantur: nec baculos pastorales gestant in manibus nec usum habeant campanarum, sed percussis baculo vel malleo tabulis, populum ad ecclesiam soliti sunt congregare*. Bells, however, were used in the Greek church in 874, if not earlier, and are reported to have been introduced from Venice. Congregations might therefore be assembled by other means than the sound of bells; and we know that at present, the hour of prayer, among the Mahometans, who many times exceed the Christians in number, is announced by a person from the top of a tower. Flodoardus remarks, respecting the use of trumpets in warning the devout,

Ære tubas fuso attollit quibus agmine plebis
Admoneat laudes et vota referre Tonanti.

An old author likewise tells us, that the signal for divine worship was given by trumpets, *signa quæ nunc per campanas dantur, olim per tubas dabantur*. And he gives the following etymology of the word, which we observe is not to be found among the classics: *Hæc vasa primum in SOLA Campanie sunt reperta unde sic dicta: Majora quippe vasa dicuntur campanæ a Campanie regione: minores nolæ a civitate Nola Campanie*. Innocentius Ansaldus is of opinion, that all signals of hours were anciently given by trumpets, and that it was scarcely before the sixth century that bells were used in churches.

The period of introducing bells into the churches of England is not completely ascertained. Bede, in alluding to the year 680, or near that time, says, *audivit subito in aëre notum campanæ sonum quo ad orationes excitari vel convocari solebant*. After that they probably became common, and were the subject of pious donations, both here and on the continent. Turketulus, abbot of Croyland, who died in 975, caused a very large bell to be made, and presented it to his abbey. It was called Guthlac. His successor Egelricus also caused two large bells, called Bartholomæus and Bettelmus, to be made, two of middle size called Turketulus and Tatwinus, and two smaller called Pega and Bega. When

the bell Guthlac was rung along with these, Ingulphus affirms that such wonderful harmony was produced, that there was no ringing in all England to be compared to it.

Thus we see, that bells bore certain names, which has led to an animated controversy, whether they were baptized or not. Considering the extravagant ceremonies, and superstitions of the Roman Catholic faith, we apprehend that something very similar to baptism may have been anciently used, more especially as we find an express injunction against it. Yet those who have entered most keenly into the dispute, deem it little less than sacrilege, that baptism, which, in its pure acceptation, is a sacrament of remission from original sin, should be bestowed on inanimate substances. The ceremony used, if not baptism in the strict sense, was undoubtedly consecration, or benediction, and at the same time a name was given. The bishop performing the consecration made five crosses, pronouncing these words, *sanctificetur et consecretur Domine, signum istud, in nomine patris filii et spiritus sanctus. In honorem sancti N. Pax tibi.* By this formula the bell was consecrated in honour of a certain saint; but some of the chronicles go further, and compare the ceremony to actual baptism—*Signa quinque: unum ex his mirabile in quo duo millonaria metalle et sexcentæ libræ fuerunt cui imprimi jussit signum baptismi de oleo et chrismate facti: Sicut ordo deposcit ecclesiasticus et ut vocaretur Robertus attribuerit spiritus sanctus.* In the *Chronicon Montis Sereni* it is said, that a bishop Humbert consecrated a bell of fifty hundred weight, calling it Petronilla. Pope John XIII., in 968, consecrated a new bell of great size in the lateran, and gave it the name of John. All the more remarkable bells were named, or had legends inscribed on them: thus on one of two old bells in England, there is to be read:

Hæc nova campana Margareta est nominata;
and on the other, in the same place,

In multis annis resonet campana Johannis.

Such inscriptions were often in honour of some saint, as if to remind the people of a sanctified name when the bell was rung, or to render the saint propitious to the donor and the flock. They expressed the weight and quality of the bell, or the properties which it possessed, and this sometimes led to the elucidation of historical facts: In a tower of St Peter's at Rome were five bells, most of which were explanatory of some fact, and inscribed with several Latin verses; one was hung in 1258, during the ministry of a certain person; another was cast in 1353, after the lightning had destroyed former bells in the preceding year. Bells frequently bear the date, and an apposite legend. In the church of the Jesuits at Rome, there was one brought from England, which was inscribed *Facta fuit A. Dom. 1400, die vi. mensis Septembris; Sancta Barbara ora pro nobis.* Five bells being cast for a parish church in England, each had an inscription in Latin hexameters, expressing its name, or that it was to be rung in memory of those individuals whose names were recorded on them.

In regard to the superstitious uses of bells, we shall probably find the ringing of them at funerals to have originated in the darkest ages, but with a different view from that in which they are now employed. It has been supposed, and we believe with some justice, that the most ancient bells or cymbals were made of brass. A certain virtue was conceived to reside in that metal:

the knives used in sacrifices were made of it: it entered the composition of the sacred utensils in the temples; the sound of it put demons to flight, and witches used it in their incantations.

Omnia trita simul que sanguine mista recenti
Coxerat ære cavo viridi versata cicuta OVID Met. IV.

Reasoning from the customs of the ancients, that have been transmitted to us in innumerable superstitions, which extensive analogies only enable us to recognise, we may partly connect the ringing of bells for persons in the agonies of death, with the virtue supposed to reside in the sound of brass. It was to avert the influence of demons. But if the superstitions of our ancestors did not originate in this imaginary virtue, while they preserved the practice, it is certain that they believed the mere noise had the same effect; and as, according to their ideas, evil spirits were always hovering around to make a prey of departing souls, the tolling of bells struck them with terror.

We may trace the practice of tolling bells during funerals to the like source. This has been practised from times of great antiquity; the bells being muffled for the sake of greater solemnity, in the same way as we see drums muffled in military funerals. Possibly it was also with the view of averting the influence of evil spirits, as the soul was not believed to pass immediately to the regions of light or darkness. The efficacy of bells, and of other noises, in putting demons to flight, is recorded among the ancients; and from them was widely extended, during the more barbarous ages. An eclipse of the moon was supposed to be the oppression of evil spirits, and the intelligent Pliny observes, *Viri ingentes, inter quos fuit Stesichorus et Pindarus, crediderunt lunam eclipsin et quasi mortem pati ex cantationibus unde ne illi luna pateretur dissono crepitu succurrerant:* and the ringing of bells during eclipses, is particularly spoken of by Juvenal:

——— Verborum tanta cadit vis
Tot pariter pelves, tot tintinnabula dicas
Pulsari. Jam nemo tubas, nemo æra fatiget
Una laboranti poterit succurrere lunæ. Sat. vi.

In Italy, this custom was preserved at a much later date: for during great tempests, the women assembled, ringing bells, and beating cymbals, in the noise of which, the learned Moresin observes, they confided more than in the efficacy of fasting and prayer. On St John's day, the bells were violently rung, and other superstitions practised, to put devils to flight, and avert the effect of storms, which they raised in the air.

We are therefore entitled to conclude, that the ringing of bells for persons in the agonies of death, at funerals, and to dispel tempests, has originally had relation to one common object, the expulsion of demons. Here also we may seek the consecration, or exorcising of bells, practised in the Roman Catholic churches, and perhaps the cause of naming them after particular saints. In the councils of Cologne it is said, "let bells be blessed, as the trumpets of the church militant, by which the people are assembled to hear the word of God: the clergy to announce his mercy by day, and his truth in their nocturnal vigils: that by their sound, the faithful may be invited to prayers, and that the spirit of devotion in them may be increased. The fathers have also maintained, that demons affrighted by the sound of bells

calling Christians to prayers, would flee away; and when they fled, the persons of the faithful would be secure: that the destruction of lightnings and whirlwinds would be averted, and the spirits of the storm defeated." All these things were promoted by consecration; and a credulous bishop narrates several miracles displayed by consecrated bells, which, without much difficulty, we can trace to natural causes. Durand, the author of the *Rituals of the Roman Church*, says, "for expiring persons, bells must be tolled, that people may put up their prayers; this must be done twice for a woman, and thrice for a man: for a clergyman as many times as he had orders: and at the conclusion, a peal of all the bells must be given to distinguish the quality of the person, for whom the people are to offer up their prayers." An analogous custom is still preserved in the north, of concluding the tolling of the bells, with nine knells for a man, six for a woman, and three for a child. When once fully introduced, it was made the subject of emolument and extortion, and those only who were rich enough to pay for it, enjoyed the benefit of the passing bell.

Innumerable absurd ceremonies were practised by the Roman Catholics in ringing bells. Each was to be rung for a certain purpose at a certain hour, and so long at a time: When the monks were to undergo discipline in their monasteries, a bell called *corrigiuncula* was rung as a signal for the commencement of self-flagellation. They were rung on particular festivals, and muffled or tied up on others. The ringing on Christmas, and in ushering in the new year, preserved among us, is a remnant of Popish superstitions. During three days of the holy week, they were to be tied up, and in their stead boards were to be beaten with an iron hammer. In the town of Newcastle, we have understood the bells are muffled on the 30th of January, though we know not whether in commemoration of the death of Charles I., or as a relic of the older ceremonies of the church. The number of bells was a kind of privilege; and privation of them a punishment. A cathedral church was entitled to seven, or five at the least; a collegiate church, to three of different sizes; and a parish church to as many, or at least two. None were to be rung in towers, until they received solemn benediction, and they were to bear no profane figure or inscription, but one in honour of the titular saint, a sacred image, or a pious legend. The city of Bordeaux was deprived of its bells on account of rebellion. When offered to be restored, the inhabitants refused them, from the satisfaction they had enjoyed in being free of the constant noise of bells. Whether these bells had been employed for sacred or profane purposes, we do not discover; but it is incredible how much of the ceremonies of the Roman Catholic religion depended on the ringing of bells, according to time and quantity.

Bells were anciently suspended from the neck of a criminal who underwent scourging, which has been construed into a warning, that people should avoid the ominous consequences of his crossing their way. We doubt if this interpretation be correct, and we should rather be inclined to consider it a signal of punishment, and a warning to the populace not to merit the like. There are towns in modern days where the bells toll during an execution, which may have originated in a warning to people to pray for forgiveness to a departing soul; but now it is chiefly to increase the solemnity of the scene.

Strabo relates, that the Troglodytes suspended bells from the necks of animals in their flocks, for the purpose of frightening away wild beasts. Some authors have supposed, that this was to disclose the places whither they had strayed: and also, that the sound of bells was pleasing to the animals themselves. The practice is continued to the present times, in bells being suspended over horses, or from mules, sheep, and goats; but we suspect that it also has originated from a superstitious custom, and that the sound of the bells was to restrain demons from injuring the animals. Kings and nobles, anciently, had the housings of their horses hung with silver bells. Zachary the prophet, speaks of the bells of horses.

As bells were of old the subject of pious donations, he who could give the greatest gift claimed the most merit, which has perhaps tended more than any thing else to the enormous size of several bells, of which we read in history. In addition to those large ones already named, may be mentioned, a bell presented by king Edward III. of England to St Stephen's Chapel, which, according to an inscription on it, was 33,000 weight. Sallengre, or Swertzius, the commentator on Hieronymus Magius, tells us, that the largest bell in all France hung in St Mary's church, at Rouen, in a lofty tower. It bore an inscription in these words, which are always erroneously quoted:

Je suis nommée George d'Amboise,
Qui plus que trente six mil poise;
Et si qui bien me poysera,
Quarante mil y trouvera.

This bell was presented to the church by George, archbishop of Rouen, and the tower containing it was equally famous. A great scarcity of oil prevailing in the diocese, so that there was hardly enough for Lent, the archbishop permitted the inhabitants to use butter, on each paying sixpence for the indulgence. From the sum thus collected, the tower was built, and always thereafter was called the *Tour de la Beurre*. The great bell at Moscow, of which we have spoken, and which hangs in the tower of St Ivan, is 40 feet 9 inches in circumference, 16½ inches thick, and weighs above 57 tons, or 114,000 pounds. The city of Nankin, in China, is much celebrated for the size of its bells. One of these, almost of a cylindrical figure, is nearly 12 feet high, and 7½ in diameter: and there are said to be seven bells in Pekin, each weighing 120,000 pounds. Yet, contrary to what we are told of the Russian bell, the tone of these is reported to be of very indifferent quality, partly in consequence of being struck with a wooden clapper. Such bells are inconsiderable, compared with an immense one at Erfurth, in Germany, which was long supposed the largest bell in the world. We do not know if it be still there. The clapper of this immense bell weighed 1100 pounds, and was 12 feet long, and its sound, when the wind was not adverse, was heard at nine leagues distance. A great artist, named Gerardus Wou de Campis, cast it in 1497, and the expense was defrayed by a subscription raised among the great and wealthy, for the whole weighed 252,000 pounds. In correspondence with the ancient custom, it was dedicated to the Virgin Mary, and bore a legend: *Laudé patronos cano gloriosa, fulgur arcens et demones malignos, sacra templitis a populo sonanda carmine pulso*; which words are explanatory of the efficacy supposed to reside in the sound of bells. Possibly no larger bells than this

at Erfurth, and the other at St Ivan's tower in Moscow, have ever been hung: for although there be one far exceeding the dimensions of either, and indeed of both united, it has not been suspended. We allude to the great bell of Moscow, emphatically termed by Dr Clarke, "a mountain of metal." The exact dimensions of the great bell are not ascertained, owing to the rim lying buried in the earth; but measured two feet above the ground, its circumference is 67 feet 4 inches. The perpendicular height is 21 feet $4\frac{1}{2}$ inches, the metal measures 23 inches in the thickest part, and the weight of the whole is 443,772 pounds. A large proportion of silver is said to have been employed in casting it; for while the metal was in fusion, the nobles and people threw in their plate and money as votive offerings: and it certainly has a white shining appearance, according to authentic accounts, unlike bell metal in general. There is a great fracture in one side, which was occasioned by water poured on it while hot. The building or scaffolding erected over the pit in which it was cast having taken fire, the metal heated, and the water employed in extinguishing the flames had that effect. The bell never was removed from the pit; therefore, what is commonly related of the tower where it was hung having taken fire, and the beam suspending it being burnt, whence it fell and was broke, is not true. At present the pit is covered with a trap door: and on festival days, the bell is visited by peasants, with as much devotion as they would visit the shrine of a tutelar saint. The Russians regard it with superstitious veneration, inasmuch that they would not allow Dr Clarke to file off the smallest quantity for the purpose of assaying the metal. It was cast in the year 1553.

The people of England are said to be peculiarly partial to the ringing of bells, and, to acknowledge the truth, the disagreeable sameness of chiming is found in almost every country town. Paul Neutzner, who travelled in England between 1550, and 1560, says, "they are vastly fond of great noises that fill the ear, such as the firing of cannon, beating of drums, and the ringing of bells: so that it is common for a number of them that have got a glass in their heads, to get up into the belfrey, and ring the bells for hours together, for the sake of exercise." Neutzner's observation tends to prove the strong propensity of mankind to testify their satisfaction by noise; hence the custom of ringing bells as a mark of rejoicing.

Hand-bells were first used in religious ceremonies, and then in feats of mimicry and pastime: and even in more modern times, it was considered dexterous to ring a great number at once. The late Mr Joseph Strutt observes, that he saw a man in London ring twelve bells at a time: two were placed on his head, he had two in each hand; one was affixed to each knee, and two upon each foot; all of which he managed with great adroitness, and performed a vast variety of tunes.

Music bells, or barillions, are preserved in several parts of Britain; and in many towns of the continent. They are played by means of keys resembling those of a piano forte, and when well tuned and heard at a distance, the music is not disagreeable. It is not evident when they were first introduced, but they may be of considerable antiquity, the number augmenting according as alterations were made in music. Prefixed to a manuscript copy of the Psalms, as old as the fourteenth century, is a painting of King David playing with a hammer in each hand, on five bells hung up before him. In the great

tower of the cathedral in Antwerp were suspended thirty-three music bells, the largest seven feet wide, and eight feet high, the melody of which is highly celebrated.

The use of great bells having declined, there is less attention paid to their fabrication. One family in Gloucester, Sir John Hawkins observes, continued casting bells from 1684 to 1774; and by a list which they published, the number amounted to 3594. See Calmet *Dissertatio in Musica Instrumenta Hebræorum*. Lampe, *de Cymbalis Veterum*. Laurentius, *Collectio de Citharædis Fistulis et Tintinnabulis*. Hieronymus Magius *de Tintinnabulis*. BELL ROCK, the name of a rock in the German ocean, formerly called the SCAPE, and the INCH CAPE. The word *Scape*, in reference to this rock, may be considered a corruption of *scawp*, or *scalp*, a bed of shell fish; or as arising from a resemblance which the rock may at one time have had to a *bee-hive*. The term *Cape*, a headland or promontory, applied to a sunk rock, otherwise than by supposing it a wrong pronunciation, seems preposterous, and undeserving of serious attention.

To account for *Bell Rock*, which has now become the prevalent name, it is said that the abbots of the monastery of Aberbrothwick caused a bell to be erected upon it, in such a manner that the tides brought certain machinery into action, which rang the bell, to warn seamen of their approach to the rock. Tradition says, that this apparatus was carried away by a Dutchman, who, to complete the story, was afterwards lost upon the rock, with his ship and crew. It would be difficult to conceive any machine of this kind, which, in such a situation, could have been useful. Its removal in the way represented is disgraceful to human nature, and, besides according ill with the proverbial honesty of the Dutch, is incompatible with the veneration which all seamen are known to possess for landmarks.

The probability rather seems to be, that we are indebted only to traditionary story for the bell, and that this name took its rise in a more natural way, from the shape of a part of the rock, now removed, to make way for the scite of the lighthouse lately erected upon the rock. Although this rounded part was only about four feet above the general level of the rock, yet, by supposing it the nucleus of a larger mass, it might readily suggest the idea of a bell, and give rise to the Scottish phrase, a *bee-scape*.

Scape is the name found in the oldest sea charts; *Cape*, or *Inch Cape*, in those of more modern date; and *Bell Rock* in the charts of the present day, which renders the other names obsolete.

The Bell Rock may be viewed as directly opposing the entrance of the firths of Forth and Tay to all vessels from a foreign voyage; and lying more or less in the way of coasters, as their track may be northward or southward of the island of May. It is situated in W. Long. 2° 22', and N. Lat. 56° 29', 11 miles south-west from the Redhead in Forfarshire, 17 miles north-east from the May lighthouse, and 50 miles north by east from St Abb's-head, in Berwickshire.

The rock is a red sandstone, apparently of the same formation with the Redhead in Forfarshire, and similar to the stone at Dunglass, in Berwickshire. In some

places it is variegated with stripes of white passing into brown; it is fine granular, containing minute specks of mica, and is hard and difficult to work. Its angle of inclination with the horizon is about 15° , and it dips towards the south-east. The strata are thick and unequal, strongly connected together, and run in the direction of north-east and south-west.

The surface of the rock is very rugged, being full of cavities, owing to the fracture and overlapping of the strata. It may be described as consisting of an upper and a lower level. The north-east end, which is the higher, is only partially left by the tide at low water of neap tides; while the south-west, or lower level, appears only in spring tides. Taking the dimensions of the rock at low water of spring tides, the greatest length of the higher part measures 427 feet, and 230 feet in breadth. The greatest length of the reef, or lower part, which the water never wholly leaves, extends 1700 feet from the main rock, in the direction of the stratification: the breadth of this reef is less than that of the main rock, and diminishes towards the western extremity. The greatest length of the rock seen at low water of spring tides is 2127 feet, and the greatest breadth is 230 feet. The reef, or south-west part, being on a level with low water of spring tides, is consequently, at high water, under the whole rise of the respective tide; while on the higher part, which is in general about four feet above low water-mark of spring-tides, and consequently about twelve feet under water at the height of ordinary spring tides.

The same laws are observable in the rise and fall of the tides at the Bell Rock, as on the opposite and most contiguous shores of Forfarshire. On the days of new and full moon, it is high water at the rock at 40 minutes past one o'clock. The ordinary rise of spring tides is about fifteen feet, and of neap tides nine feet; but so much depends upon the state of the weather, that the tides vary from one to three feet in the rise and fall both of spring and neap tides; so that at low water much less of the rock will appear at one time than at another: and instead of shewing itself at low water of neap tides, it is sometimes from one to three feet under the surface of the water. Westerly winds have always a tendency to raise the tides higher, while easterly winds have a contrary effect. In moderate weather, the course of the flood-tide is south-west, and of the ebb-tide north-east, with some little variation, according to the time of tide. Spring tides have a velocity of three miles an hour near the rock, and neap tides about a mile and a quarter.

It is not a little remarkable, that so small a rock should follow the same laws in influencing the current with the coast of a country. Upon the rock it is flood-tide two hours before the ebb ceases to run at the distance of half a mile; so that the flood-tide will have almost covered the rock, while vessels in the offing are striving with an ebb-tide. The same thing is observable in a greater or less degree, according to the velocity of the tide, along all coasts; and the mariner accordingly knows how to shun an adverse tide, and to seek one in his favour, by keeping nearer, or at a greater distance from the shore.

The lower parts of the rock are covered with fuci, chiefly of the larger sorts, as the great tangle, *fucus digitalis*, and the badderlocks, or hen ware; which last is found of the length of 18 feet, and must then be very aged, as plants of the first year's growth are but a few inches long; and in two years they are found to be only

about 18 inches in length. The higher parts of the rock abound with smaller fuci; as *F. mamillosus*, and *F. palmatus*, the common dulse; *F. alatus*, and *F. coccineus*, are found on the older stalks of tangle; and *F. subfusus* and *confervoides* occupy the smaller pools. In some places the rocks are rendered slippery with *ulva compressa*, and *umbilicalis*; and the higher parts are so thickly covered with *conserva rupestris*, as to resemble a sward of grass.

The rock is covered with *lepas balanoides*, and some parts abound with the common limpet and muscle; *actinia crassicornis*, with star-fishes; *asterias glacialis*, and *oculata*, are common. Common crabs of a large size, and a few lobsters, are found. Seals frequent the rock at low water, and it then becomes the resort and resting place of cormorants, shags, and herring-gulls, which feed on the haddocks and codlings found around the rock.

When the building of the light-house was begun, there was not a muscle to be seen upon the rock; but in less than four years, the north-east part was completely covered with muscles of a small size. These appeared to have been propagated from a few deposited for a stock of bait for the workmen engaged at the building, who were in the practice of employing their leisure hours in fishing. It is, however, to be feared, that the muscles will very soon be extirpated by their natural enemy the white bucky, *buccinum lapillus*, which seems to be increasing "in proportion to the means of subsistence;" and is rapidly destroying the muscle, by perforating a very small hole with its proboscis, through which the substance of the muscle is sucked out, when the shell opens, and is washed away by the tide.

From the various depths of water, and the variety of the bottom, which alters as the distance of the rock and the soundings are increased, from a rocky bottom, to coral, rough sand, rough gravel, shell sand, fine sand, and mud, which is found in the course of the tide from the Tay. From the circumstance of this variety, the following kinds of fish are caught near the rock in great abundance, and of excellent quality. The red-ware cod, close to the rock; and at a greater distance, the common cod, ling, holibut, skate, thornback, plaice, turbot, gurnard, wolfe fish, phod, dog-fish or leacdy, coal-fish, whiting, haddock, flounder, sole, mackerel, and herring.

It is worthy of remark, that when the weather becomes very cold in spring and autumn, and when the sea is agitated much by the wind, the fish appear to leave the vicinity of the rock, and perhaps go into deeper water. Of this, ample proofs have been afforded by the lighthouse vessels riding off the rock at all seasons of the year.

The Bell Rock is exposed to the waves of the ocean in the directions of north-east, east, and south-east, without any land between it and the continent of Norway and Jutland; on the opposite points of the compass, it lies open to the shores of Berwick, Haddington, Fife, and Forfar. Relatively to the two last counties, it may be considered as holding a central situation in a capacious basin, with a depth of water increasing from the shore till within two miles of the rock, where the ultimate depth is 23 fathoms; and from thence to the rock the soundings gradually diminish. At low water of spring tides, and at the distance of 100 yards from the rock, in all directions, there are about three fathoms water. On the south-east side, in the direction of the inclination of the strata, the water deepens more suddenly to 35 fathoms; and as you stand out to sea, the soundings be-

come less and less; and at the distance of 30 miles, the water is only 22 fathoms deep upon Marr's Bank, which appears to be a deposition formed by the joint-operation of the waters of the Forth and Tay, influenced by the great wave of tide which proceeds round the island.

From the gradual increase of the depth of water in all directions from the rock, it must satisfactorily appear that it has a sufficient base to support it for ages, against the impression of the sea. By an attentive consideration, however, of the form of the rock under water, and of the ground which surrounds it, together with the nature of the stone, and the probable effects of the continued wash of the sea violently agitated; it does not seem an overstrained hypothesis to imagine, that this rock, at a remote period, was of much greater extent, and perhaps considerably above the level of the highest tide.

From the position of this rock with regard to the much frequented firths of Forth and Tay, lying about 11 miles from the nearest land, a distance too great for the mariner to be benefited by land-marks on the shore; while the rock itself is only visible about two hours before low water of spring-tides, even to vessels near it, and is scarcely seen at all in neap-tides. The Edystone rocks off Plymouth are at the same distance from land as the Bell Rock; but previous to the erection of the Edystone lighthouse, the highest, or house rock, was always seen above the surface of the water, and to a certain extent formed a beacon of itself in the day-time, which was not the case at the Bell Rock. Under these circumstances, the Bell Rock has been justly considered the most dangerous reef of rocks upon the whole coast of Great Britain; and must have proved fatal to many missing ships, whose fate must for ever remain unknown.

The baneful effects of such an obstruction to navigation had been long and severely felt, not only by the commercial interest of these firths, but in a greater or less degree by all vessels navigating the North Sea and the German Ocean. Not merely were vessels lost upon the rock itself, but far greater numbers were cast away upon the neighbouring shores in endeavouring to avoid it, or foundered at sea in consequence of keeping out too long, from the terror of approaching the coast where such a sunk rock lay in their course.

The three great inlets for shipping in storms upon the east coast of Great Britain are, the Thames, the Firth of Forth, and the Murray Firth. To these vessels resort, in storms from the north, east, and south-east; and in such cases the Firth of Forth lies open in a peculiar manner as a place of safety. Of this the dreadful and continued gale from south-east, which occurred in the month of December 1799, affords a memorable and striking instance, when the ships in Yarmouth Roads were driven from their moorings, and all vessels in the German Ocean drifted upon the coast of Scotland, a very great number found shelter in this Firth. Many, however, were wrecked in endeavouring to seek safety in higher latitudes: and it has been reckoned that seventy vessels were upon this occasion lost, with most of the crews, upon the east coast of Scotland; many of which might have been saved had not the fear of the Bell Rock in a great measure induced them to avoid entering the Firth of Forth.

It is no wonder that the erection of a lighthouse upon the Bell Rock should have so much interested the public mind, not as a local improvement only, but as one essentially calculated to improve the navigation of the

whole north seas, by opening the Firth of Forth as a general rendezvous for shipping in easterly storms. By such an erection, seen as a beacon by day, and exhibiting a light under night, this most dangerous rock is rendered at once the place of departure which ships will hail from, and for which they will steer in making the coast.

On the completion of a work of so much enterprise and difficulty as the Bell Rock lighthouse, we most heartily congratulate the public, and willingly contribute our mite of praise to that Honourable Board the Commissioners for erecting lighthouses on the northern parts of Great Britain, whose improvements pervade the whole coast of Scotland. By them this measure was taken up and brought before Parliament in the year 1807. The foundation stone was laid on Sunday the 10th of July 1808, and the whole was finished within the year 1810. See the article LIGHTHOUSE. (s)

BELLARMIN, ROBERT, an Italian Jesuit, and the ablest of all the Roman Catholic controversialists, was born at Monte Pulciano, a town in Tuscany, in the year 1542. At the age of eighteen he entered into the order of the Jesuits; he was ordained priest at Ghent in 1569; and as he was nephew to Pope Marcellus II, he had the fairest prospects of ecclesiastical preferment. His talents, however, were a still stronger recommendation. In 1570, he was appointed professor of divinity in Louvain, where he acquired a very high degree of celebrity. After residing seven years in the Low Countries, he returned to Italy, and began to lecture on controversies in Rome. His lectures displayed such uncommon acuteness and ingenuity, that when Pope Sextus V. sent a legate to France, in 1590, he appointed Bellarmin to attend him, as the person best qualified to resolve any difficulties which might occur in the course of his mission. After an absence of ten months, he returned to Rome, and received from the friendship of three successive popes, various important commissions, till at length, in the year 1599, he was raised to the dignity of cardinal. Nothing could be more honourable to Bellarmin, than the manner in which this dignity was conferred. "We chose him," said his Holiness, (Clement VIII.) "because the church of God does not possess his equal for learning;" yet he felt or affected such reluctance to accept of it, that Clement was obliged to frighten him into compliance by the terror of an anathema. Three years after, he was elected archbishop of Capua; and had he not belonged to the order of Jesuits, he would probably have been exalted to St Peter's chair. But that intriguing set of men were already so powerful, and so eager for the monopoly of ecclesiastical dignities, that it had long been a maxim at the court of Rome, that no Jesuit should ever be made pope, lest every other order should be excluded from the hope of the papal dignity, and the power of the Jesuits should become altogether boundless. Bellarmin, if we may believe his own confession, was by no means ambitious of that exalted honour. For in a solemn vow made in the prospect of being advanced to the see of Rome, he expressly says, that he does not at all desire it, and prays to God that it may never happen. He resigned the archbishopric of Capua at the request of Paul V., who wished to have him near himself; and continued for sixteen years actively engaged in the business of the court of Rome. He left the Vatican in 1621, and retired to a house of his own order, where he died the same year on the 7th of September, at the age of 79.

He was visited in his last illness by Pope Gregory XV., his veneration for whom, as Christ's viceregent upon earth, he expressed in the words of the centurion, "Lord, I am not worthy that thou shouldst come under my roof." On the day of his funeral, the populace, who revered him as a saint, crowded in such numbers about his body, in order to touch and kiss it, that it was necessary to keep them off by a military guard. His garments, and every thing which he had been accustomed to use, were distributed as most venerable relics. It was pretended, too, that he had been endowed with the spirit of prophecy, and possessed the power of working miracles. All these appeared natural preludes to his canonization; and nothing prevented the popes from admitting him into the calendar of saints, but the fear of giving offence to those princes whose temporal rights he had denied.

The character of Bellarmine has been very variously represented; but to his talents as a controversial writer, the acrimony of his adversaries may be regarded as even a less equivocal testimony, than the extravagant admiration of his friends. No champion of the church of Rome ever defended her cause with more zeal or ability. His works were regarded by the Protestants as so many bulwarks planted around the papal throne, which could not be assailed with any hope of success, till these bulwarks were first battered down. Every divine, therefore, who waged war against papacy, singled out Bellarmine as the principal object of his attacks, and it is said that a new lecture was instituted in both the English universities, for the express purpose of confuting his arguments. The modes of hostility practised against this arch enemy of the reformation, varied with the temper and abilities of his assailants. He himself set them an example of fair and honourable warfare, which they would have done well to imitate. He disdained the low artifices of concealment and misrepresentation; and confident in his own power of reply, stated the arguments of his opponents so fully and forcibly, that it has been alleged that his writings contain the best defence of those doctrines which he meant to refute. It is certain that his candour in this respect gave so much offence and alarm to many zealous Catholics, that they wished his writings to be suppressed, lest the heretics should make use of them to their own advantage, and the Catholics should be imposed upon by not understanding the answers as well as the objections. His most celebrated work is entitled *A Body of Controversy*, the arrangement of which is clear and methodical, the reasoning ingenious and profound, and the style, if not elegant, at least nervous and plain. That a controversial work of four folio volumes, particularly if written in a bad cause, should contain inconsistencies, is almost unavoidable; and the adversaries of Bellarmine have exposed his contradictions with as much triumph as if they completely invalidated his ablest arguments. This is more excusable, however, than the calumnies which they have forged against his character. A libel was published against him, while he was yet alive, stating some circumstances which occasioned, attended, and followed his death. Among other accusations it was pretended, that he had caused many children to be murdered in order to conceal his incontinence; that, touched with remorse, he repaired to Loretto to expiate his crimes by confession, but that the priest to whom he made the avowal, was struck with such horror, that he abruptly ordered him to depart, and that Bellarmine died

in despair.—Bellarmine read and laughed at the charge, which was the most improbable that the blindness of malice could devise; for so exemplary was his purity, that on an inscription placed under his picture, it could be recorded that he preserved his chastity and his baptismal innocence, and that he never told a lie. His temper was so mild that he could bear the greatest injuries without resentment, and rather than molest the meanest insect would allow them to incommode him extremely, since to fly and stop where they please is their only heaven, of which it would be cruel to deprive them. At his death he bequeathed one half of his soul to Jesus Christ, and the other half to the Virgin Mary; and with his latest breath enjoined a friend to declare to the public, that he died in the same faith which he had always professed and maintained. Besides *A Body of Controversy*, he wrote *A Treatise on Ecclesiastical History*; *A Treatise on the Temporal Authority of the Pope*; *The Groans of the Dove*; *On the Obligations of Bishops*; *A Commentary on the Psalms*; *A Hebrew Grammar*; and *Sermons*. See *General Biography*; Ancillon's *Mélanges Critiques de Littérature*, tom. i.; and Mosheim's *Ecclesiast. Hist.* vol. iv. p. 221, &c. (k)

BELLEISLE, an island of France, in the department of Morbihan, situated in the Bay of Biscay, about six leagues from the coast of France. It is about six leagues long, and two broad, and is so surrounded with sharp pointed rocks, that there are only three places, well fortified, by which the island can be attacked. The soil of this island, naturally fertile, is manured by means of a weed called goesmon, or vareck, which is constantly thrown upon their shores. Corn of different kinds is there produced in abundance, and form the articles of their commerce. The principal commerce of Belleisle, however, consists of sardines, which are fished on the coast to the extent of 3000 barrels a year, each barrel containing about nine or ten millions of sardines. No fewer than 150 chaloupes, of two or three tons each, are employed in this fishery, which is carried on from June to October. A barrel of oil flows from about thirty or forty barrels of sardines, by means of small holes pierced in the bottom of each barrel. The sardines are exported to Bilboa, St Sebastian, Bayonne, and all the places along the Garonne; and the oil is partly consumed in the island, and partly exported to Bourdeaux and Nantes. The whole commerce of the island is said to produce annually between 140 and 160 thousand francs. There are also salt marshes in this island. Belleisle once belonged to the family of Fouquet, and was exchanged for the county of Gisors. Palais and Bungor are the chief places of the island, which contains likewise about twenty villages. Chantreaux, in one place of his *Science de l'Histoire*, makes the population of Belleisle 2436, and in another between five and six thousand. West Long. 3° 6' 30", North Lat. 47° 17' 30". (q)

BELLENDEN, JOHN, archdeacon of Murray, and canon of Ross, was a native of Scotland, but the year of his birth is uncertain. His education seems to have been liberal; and, according to George Con, he took the degree of doctor of divinity in the Sorbonne. (*De Duplici Statu Religionis apud Scotos*, p. 167) Dr Campbell has remarked, that his phraseology occasionally savours of a French education. His *History and Chronikles of Scotland*, a free translation of the first seventeen books of Hector Boyce, was undertaken at the request of James the Fifth, whose favour he seems to have en-

joyed. Into this publication he has introduced two poems of considerable length, entitled, *The Proheme of the Cosmographie*, and *The Proheme of the History*; and has closed the whole by a prose *Epistil directit be ye Translatoure to the Kingis Grace*. If we may credit Dr Mackenzie, this work was printed in the year 1536; but his source of information it would be difficult to discover, for the title-page and colophons exhibit no date. Mr Herbert, without any apparent foundation, mentions the publication of another edition in the year 1541. Bellenden likewise translated the first five books of Livy; and a manuscript copy of his version is preserved in the Advocate's Library. From a passage in the poetical *prologue*, it appears, that this work was also undertaken at the suggestion of king James. In the same poem he expresses an intention of executing a complete version of Livy's Roman History; but this formidable task he seems never to have performed. According to Dempster, he died at Rome in the year 1550. Of the original compositions of a writer who discovers such a fine vein of poetry, it cannot but be regretted that so inconsiderable a portion has been preserved. His poems are the effusions of an excursive fancy and a cultivated taste. He has been extolled as a master of every branch of divine and human learning; and it is at least apparent, that his literature was such as his Scottish cotemporaries did not very frequently surpass. "He was unquestionably," says Dr Campbell, "a man of great parts, and one of the finest poets his country had to boast. So many of his works remain as fully prove this; inasmuch as they are distinguished by that noble enthusiasm which is the very soul of poetry." The most poetical of his works is, *The Proheme of the Cosmographie*. The principal incidents are borrowed from the ancient allegory of the choice of Hercules; but he has impressed his transcript with the characteristic features of an original. See Irving's *Lives of the Scottish Poets*, vol. ii. p. 119. (e)

BELLENDEN, WILLIAM, a Scottish author of high accomplishments, was one of the masters of the English court of requests. According to Dempster, he had been a professor of humanity in the university, and an advocate in the parliament of Paris. (*Hist. Ecclesiast. Gent. Scotor.* p. 119.) The time of his birth and of his death has not been ascertained; but he flourished after the accession of king James to the crown of England. His three books *De Statu* are known to every man of letters; and it is sufficient praise to say, that they have been found capable of attracting the attention of an editor so accomplished as Dr Parr. (Lond. 1787, 8vo.) On the ingenuity, learning, and taste of Bellenden, this excellent scholar has bestowed unreserved commendation. Bellenden's posthumous work *De Tribus Luminibus Romanorum*, (Paris, 1634, fol.) though it extends to no fewer than eight hundred and twenty-four pages, is only to be considered as a fragment. The first of his three ornaments of Rome is Cicero; and the other two, whom he had in view, are supposed to have been Seneca and the elder Pliny. The apparent object of that portion of his work which is completed, is to combine, in an historical form, such of the observations and sentiments of Cicero as relate to the religious and political affairs of Rome. His plan is executed in such a manner as to display the spirit and essence of the Roman history. The latter part of the work, or that which relates to the times of Cicero himself, is very copious and satisfactory. The epistles of Cicero have furnished him with an historical

detail similar to that exhibited in the biography of Dr Middleton; and Dr Parr has asserted in the strongest terms, that Middleton has not only selected many valuable materials from the production of Bellenden, but when it suits his purpose, has even retained their form as well as their substance. A similar accusation had likewise been preferred by Dr Warton; but the admirers of Dr Middleton may still urge, and with some appearance of reason, that such marks of plagiarism are extremely equivocal. As the materials which he is supposed to have purloined lie scattered through the works of Cicero, they are accessible to every scholar; and as Bellenden and Middleton had clearly the same object in view, it need not excite our astonishment, that two scholars, possessed of the same elegance of taste, should conduct their researches on similar principles. Bellenden has been solicitous to retain the identical expressions of his favourite author; and, by means of a skillful combination, has exhibited a production of no trivial importance. "This work," says Dr Parr, "displays the highest ingenuity and industry. Whatever in the various writings of Cicero is either sagaciously conceived or elegantly expressed, Bellenden has adapted to one great plan, and exhibited in a more splendid view. He, therefore, who is familiarly acquainted with this performance, will be enabled to appreciate the genius of antiquity, and to profit by the examples which it supplies. He will obtain an extensive knowledge of the jurisprudence and political science of the Romans; and, as from a splendid storehouse, may select all the varieties of exquisite diction." (*Præf. in Bellendenum*, p. lxx.) What plan Bellenden purposed to adopt in relation to Seneca and Pliny cannot easily be ascertained. It may, perhaps, be regarded as no absurd conjecture, that by availing himself of their productions, he intended to exhibit an enlarged view of the intellectual and physical science of the Romans. See Irving's *Dissertation on the Literary History of Scotland*, p. 104. (e)

BELLEROPHON, was the son of Glaucus, king of Ephyre, or Ephyrax. Having murdered his brother, who was called Alcimenus or Beller, he obtained the name of Bellerophon, or the *murderer of Beller*, and fled to the court of Prætus, king of Argos. Antæa, the queen of Argos, having tried in vain to seduce Bellerophon, was so enraged at his refusal, that she charged him with an attempt upon her virtue. Prætus, unwilling to inflict punishment on Bellerophon, sent him to Jobates, the queen's father, with injunctions to put him to death. Jobates refused to execute this cruel command; but complied so far with the request of Prætus, that he sent him on several dangerous expeditions against the Chimæra, against the Solymi, and against the Amazons, from all which he returned in triumph. Proud of the valour of Bellerophon, the king of Lycia gave him his daughter in marriage, and appointed him his successor on the Lycian throne. See Homer's *Iliad*, lib. vi. v. 156. *Apollod.* lib. ii. cap. 3.; lib. iii. cap. 1. *Hygin.* *Fab.* 157. and 243. *Hesiod Theog.* v. 325. *Pausan.* lib. ix. cap. 31. *Horat.* lib. iv. od. 11. *Bochart, Phaleg.* lib. 1. cap. 6. *Anc. Univers. Hist.* vol. v. p. 97. (H)

BELLES LETTRES, a term synonymous with polite literature and rhetoric. See RHETORIC.

BELLINZONE, or BELLENTZ, a town of Switzerland, and capital of a department of the same name, is a beautiful town situated at the foot of Mount Cenero, on the east bank of the Tesino, below its junction with the Musa. "It is situated," says Mr Coxe, "in a delight-

ful plain, encircled with ancient walls and battlements in good repair; to the right rise majestically the ruins of an ancient castle; to the left, separately embosomed in trees, are the castles of the bailiffs of the three regent cantons, Uri, Schwyz, and Unterwalden."—"The interior of Bellinzona by no means corresponds with its external beauty and situation; the streets are narrow, and the houses ill built." It is, however, adorned with several elegant churches, and has numerous convents. The history of this town will be found in Coxe's *Travels in Switzerland*, vol. iii. p. 301—309. E. Long. $8^{\circ} 44'$, N. Lat. $46^{\circ} 4'$. (j)

BELLIS, a genus of plants of the class Syngenesia, and order Polygamia Superflua. See BOTANY. (w)

BELLIUM, a genus of plants of the class Syngenesia, and order Polygamia Superflua. See BOTANY. (w)

BELLONA, the goddess of war, was either the sister, or the daughter, or the wife, of Mars. She prepared the chariot of Mars; she attended him in the field of battle, drove his chariot through the combatants, and animated them to war, with the bloody whip in her hand. This goddess had a temple at Rome, and was worshipped at Comana in Cappadocia, where she had above 3000 priests, who were consecrated to her service by making deep incisions in their thighs, and reserving the blood as a sacrifice to their mistress. In the time of Severus there was in York a temple dedicated to Bellona. See *Pausan.* lib. iv. cap. 30; *Juvenal*, sat. iv. v. 127; *Hygin*, *Fab.* 274; and *Bryant's Ancient Mythology*, vol. i. p. 45. (j)

BELLONIA, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY. (w)

BELLOWS, the name of a machine, by which air is propelled with great velocity through a tube, or aperture. See *BLOWING Machines.* (w)

BELLUNESE, a mountainous district of Italy, formerly belonging to Venice, but now forming a part of the kingdom of Italy. Corn, wine, and fruits of all kinds, are produced here in abundance; numerous herds of cattle are bred on the rich pastures; the forests produce great quantities of timber, which are floated down the Piava to Venice; and the mountains are rich in iron, lead, vitriol, and copper. The lake of Alleghe, in this district, was formed in a very singular manner in the year 1771. The mountain Spitz, shaken by some subterraneous convulsion, buried in its ruins seven villages situated at its base, with all their inhabitants. It filled the bed of the Cordevola, which, swelling in every direction, swept away the village of Alleghe, and formed a lake two Italian miles long, and half a mile broad. The population of this district amounts to about 47,500. (H)

BELLUNO, a town of Italy, and capital of the Bellunese, is situated on the river Piava, by means of which the inhabitants carry on a good trade in wood and timber. This town contains many excellent buildings and marble fountains, an expensive aqueduct, 14 churches, besides several monasteries, nunneries, and hospitals. Population 7400. E. Long. $12^{\circ} 15'$, N. Lat. $46^{\circ} 10'$. (j)

BELOMANCY, from *βελος*, an arrow, and *μαντεια*, divination, is a method of foretelling future events by means of arrows, which was used among eastern nations, but particularly among the Arabians. (j)

BELTS. See *ASTRONOMY Index.*

BELUS. See *BABYLON.*

BEMBA, BEMBEA, or BEMBI, a province of the king-

dom of Angola, in Africa. It partly extends along the coast, and is traversed by the river St Francisco, or Lutano, which swarms with sea horses, crocodiles, and serpents, that devour the fish, and injure the adjacent grounds. Great numbers of large and small cattle are reared in this province. The fat of these animals serve the inhabitants for ointment to their heads and bodies, while their skins, roughly dressed, furnish them with clothing. The inhabitants speak a language peculiar to themselves, though their idolatrous rites resemble those of their neighbours. See *Dapper's Description de l'Afrique.* (j)

BEMINSTER, or BEAMINSTER, a populous and flourishing town of England, in Dorsetshire, situated on the river Bist, in a deep and fertile vale, surrounded with numerous gardens and orchards. It has a manufactory of sail-cloth, and others of iron and copper goods. Population 2140, of whom 1562 were returned as employed in trade. Number of houses 311. See *Hutchins' History of Dorsetshire.* (j)

BEN-NEVIS. See *INVERNESS-SHIRE.*

BENARES, the holy city of the Hindoos, and the grand repository of their science and mythology, is situated on the northern bank of the Ganges, in $25^{\circ} 30'$ N. Lat., about 460 miles north-west from Calcutta.

The irregular and compressed manner which has been invariably adopted in forming the streets of Benares, has destroyed the effects which symmetry and arrangement would have otherwise bestowed on a city, entitled, from its valuable buildings, to the first place among the capitals of India. The streets are so extremely narrow as not to admit of two common carriages abreast. In addition to the pernicious effects which must proceed from a confined atmosphere, there is, in the hot season, an intolerable stench, arising from the many pieces of stagnated water dispersed in different quarters of the town; the filth also, which is indiscriminately thrown into the streets, and there left exposed, (for the Hindoos possess but a small portion of general cleanliness,) adds to the compound of ill smells, so offensive to the European inhabitants of this city.

The following, and most recent account of Benares, is taken from Lord Valentia's travels: "The houses are built with stone, some six stories high, close to each other, with terraces on the summit. They are whimsically painted, and the architecture is as extraordinary. Bands of carved work run, in general, round each story, by no means despicably executed; and the large masses of stone used in the walls, together with the neat manner in which they are joined, show that the masons are very tolerable workmen. The windows are extremely small, and probably they are formed in this manner to answer two purposes; first, to prevent the opposite neighbours from overlooking the apartments; and secondly, to keep the houses more cool during the winds. Our style of architecture is by no means adapted to the climate, and the large windows would be insufferable, were it not for the tattys, (or screens composed of the roots of sweet-scented grass, on which water is constantly thrown to cool the air,) which are easily applied to a house one story high, but would be impracticable in a house of six stories, and situated in a town. It is seldom that the universal custom of a country is not founded on reason: though, therefore, they have larger windows in their country houses, which can be cooled by artificial means; yet up stairs, where that cannot be done, they reduce the apertures as much as possible. The oppo-

site sides of the streets, in some places, approach so near to each other, that they are united by galleries. Several new houses are building on a very handsome scale, and the town, in general, had an appearance of prosperity, which is by no means deceitful. The city of Benares is so holy, that several Hindoo rajahs have habitations there, in which their vakeels, or envoys, reside, and perform for them the requisite sacrifices and ablutions. The land is extremely valuable, and law-suits respecting it most frequent. The number of stone and brick buildings, from one to six stories high, is upwards of 12,000. The mud houses upwards of 16,000. The permanent inhabitants are upwards of 58,000, besides the attendants on the three princes, and several other foreigners, who may amount to near 3000; but the concourse during some of the festivals is beyond all calculation. "The Mahometans are not one in ten." Vol. i. p. 104.

Such is the account which Lord Valentia gives of the population of Benares. But there is evidently a gross typographical error which materially affects the calculation. The number of houses of all descriptions is stated to amount to upwards of 28,000, whilst the population is stated at 58,000; allowing little more than two to each house, though there are whole streets composed of houses six stories high. It is evident, then, from the nature of the case, and also from the appendix to which his lordship refers us, that the inhabitants of Benares should be estimated at upwards of half a million.

Benares presents a strange appearance of prosperity and wretchedness, of the highest affluence and the most abject poverty. "In going into a mosque," says Tennant, "thousands crowded round us, soliciting charity with an importunity I never before witnessed, and which I could not then resist. Hunger, wretchedness, and disease, seemed to meet the eye in every direction: what increased our uneasiness, was the impossibility of affording relief to such crowds, whose famished multitudes pressed forward to succeed such as you had sent away with a pittance of supply. It is not any scarcity, or any extraordinary degree of poverty, that occasions this concourse of beggars, but the number of pilgrims who come from all parts for the purpose of devotion and charity." *Indian Recreations*, vol. ii.

Although Benares cannot now boast the glories of science, it is still the grand seat of Braminical learning, and presents many monuments of its former splendor. There is still remaining a stupendous observatory, containing a great number of astronomical instruments, all formed of stone, and constructed with the utmost exactness. A particular description of the observatory and instruments is given by Sir Robert Barker, in a letter to the president of the Royal Society of London, which was read before the society in May 1777. Students still resort, in great numbers, to Benares, where they are instructed, not, as in Europe, by a number of professors; but each Bramin, who undertakes the instruction of youth, receives a limited number of pupils, from four to ten or twelve, according to the celebrity of the teacher. With these preceptors they spend many years in studying Sanscrit, mythology, and metaphysics.

There is a great number of Hindoo temples in Benares, dedicated to their almost innumerable gods. There is a spacious mosque, with lofty minarets, built by Aurengzebe, on the site of a temple sacred to Mahadeva, which was destroyed to make room for it. This Mahometan pile erected on this sacred spot, was intended by the bigotted and intemperate zeal of the tyrant to insult

the religion of the Hindoos; and it has completely answered the purposes of its erection; for they consider this monument as the disgraceful record of a foreign yoke, proclaiming to every stranger, that their favorite city has been debased, and the worship of their gods defiled. From the top of the minarets is seen the entire prospect of Benares, which occupies a space of about two miles and a half along the northern bank of the Ganges, and generally a mile inland from the river. See Forster's *Travels*, vol. i. (v)

BENBICULA, one of the Hebrides, or Western Isles of Scotland, which lies between the islands of North and South Uist. From the great similarity between Benbicula and these islands, in their soil, agriculture, production, and general management, we shall reserve our historical account of this island to the article UIST. See Macdonald's *General View of the Agriculture of the Hebrides*, p. 779, Edinburgh, 1810. West Long. 7° 12', North Lat. 57° 23'. (w)

BENCOOLEN, a sea port town on the south-west coast of the island of Sumatra. After the English had lost the pepper trade of Bantam, they formed a settlement here in 1685, and Fort York was built by the East India Company in 1690. As the town and fort, however, stood on a stinking morass, a great mortality prevailed among the settlers in 1693, and the governor and council fell victims to the insalubrity of the climate. A new fort was therefore begun in a more healthy situation in 1719; but the jealousy of the natives prompted them to set fire to the fort, and the houses of the English, and compel the governor and garrison to embark for Batavia. The fears of the natives having subsided, the English were in the year following permitted to return and finish their fort, which received the name of Marlborough Fort. In the year 1760, Bencoolen was taken by the French, and Fort Marlborough destroyed. In 1763, when it was restored to the English, and Manilla ceded to the Spaniards, several Chinese merchants removed their families from Manilla to Bencoolen, where they all perished in a short time.

The town, which stands upon a morass, is about two miles in circuit, and is distinguished by mariners by means of the lofty mountain called the Sugar Loaf, which is situated in the interior of the island, about 20 miles from Bencoolen. A large and commodious bay is formed by an island which fronts the town, and by the point of Silleban, which stretches about two or three leagues to the south of it. The inhabitants of Bencoolen, whose houses are built on bamboo pillars, are mostly carpenters, who hire themselves to work in the English fort. Some of them gain their subsistence by fishing, and others by planting rice and pepper trees. The pepper, which forms the principal article of commerce, is brought from the interior by a river which runs north-west of the town; but a bar at its mouth occasions a considerable inconvenience in the shipping of it. The soil of the surrounding country is a fertile clay, which produces long grass. The country is in general woody and mountainous, and near the sea, it is a complete morass. East Long. 102° 3', South Lat. 3° 50'. See Marsden's *Account of Sumatra*; and also SUMATRA. (H)

BENDER, TEGIN, or TEKIN, a fortified town of European Turkey, and the capital of Bessarabia, is situated on the right bank of the Dneister, and is celebrated as the residence of Charles XII., when he threw himself on the protection of the Turks after the battle of Pultowa. Bender received its name from Bajazet II., when,

on his death bed, he commanded his successor Selim I. to erect a fortress in this place, having ended his exhortation with the words *Ben-Derim*, or *I command thee*. The fortress, which is only remarkable for the immense ditch which encompasses it, contains 300 cannon, 25 mortars, and three howitzers, beside an abundant supply of powder, balls, rice, meal, &c. &c. On the inner wall of the castle, or old fortress, Campenhausen observed two inscriptions, one of which was effaced, and the other written in Arabian, of which the following is a translation: Built by order of the "Stambulian Padischa Beyza-Devoly, by the powerful Padischa Sultan Selim Hazy." There are two suburbs, twelve mosques, six inns, or khauns, and seven gates; viz. the gate of Constantinople, the tanners gate, the gate of Varna, the water gate, the Uul gate, the Orda gate, and the stone gate; two of these gates are marked with inscriptions, one of which is peculiarly important, as it proves, in opposition to the testimony of the Hungarian historian, that Tegin was taken by storm, and not by treachery. The following is a literal translation:

"I, by the grace of the Highest, the first of all emperors in the world, Sultan, form of God, and of his prophet Muhamed, companion of the Lord, conqueror of the world, and of the Woywod Peter, and of Bogdania, I, Solyman, seal bearer of the temple of the only God, I, I have wrested the fortress of Tegin and its garrison from the king of Germany; I have taken it by storm, in the presence of all the chiefs of my ever invincible army; and I have given orders to have the stones taken from the castle of Palanka, to build this wall and gate; and the fortress shall be named Ben-Derim. In the year of the Hegira 965."

The principal mosque, called Muynkar-Dgammid, is a kind of cathedral where the people assemble on Fridays only, in which alone it is lawful to pray for the Sultan. The streets of Bender are narrow, gloomy, and dirty, and the carcasses of horses, oxen, dogs, &c. lie putrifying in the streets. The inns are large square buildings resembling convents; the windows look into a court yard encircled with a high wall; and there is a number of small chambers without furniture, in which travellers lodge, and foreign merchants expose their goods to sale.

The large metsched, or mosque, is a building 58 paces square, and is the finest edifice in Bender. Over the principal entry is a cornice, containing a verse of the Koran, written in golden letters. A metal bason is suspended by a chain in a niche, opposite the door; and on the left of this, there is a recess with a representation of the Kaba, and the tomb of Mahomet. To the right of the metal bason is a small pulpit, with ten steps covered with red cloth, from which the Iman reads the Koran. The floor is adorned with rich carpets, and divans are placed round the walls. There is a cupola in the middle of the building, ornamented with a red star, from the centre of which is suspended a lustre, having its branches loaded with several hundreds of glass lamps of various colours. Several ostrich eggs are suspended above this lustre. A prayer against the plague is written on the wall, and on one side is a painting of the sabre of Ali. The ruins of the house where Charles XII. resided, and the remains of his entrenchment at Varnitza, are still to be seen; but the inhabitants are completely ignorant that their town was honoured with the presence of this distinguished hero.

There is a great number of tanners in Bender, three

paper manufacturers, several smiths, and a watch-maker. The paper is made of cotton, and smoothed with glass, and the ink is obtained from the bark of the alder. Bender is the residence of the principal Sandgiack of Besarabia, who has an yearly salary of 3000*l.* sterling, and a number of provincial governors under him.

Bender is celebrated for the famous siege which it underwent in the year 1770. On the 30th of July, the Russian army under Count Pavin, opened their trenches and bombarded the town, but the garrison and the inhabitants defended themselves with great bravery, and annoyed the besiegers by numerous sorties. A new species of mine, called the globe of compression, invented by a French engineer, was tried on this occasion for the first time. It was charged with 16 pounds of powder, and blew up at ten o'clock at night with most tremendous effect. Amidst the terror and uproar which attended this fatal explosion, the Russian soldiers began their assault. Having got possession of all the out-works, they climbed the walls in every quarter; a furious contest ensued, and the streets, and even the houses, were filled with the bodies of the besiegers, and the brave inhabitants. Irritated at the resistance of the garrison, the Russians set fire to the town; but they were still unable to subdue the ferocious spirit of the Turks, which displayed itself even amidst the ruins of their houses, and their walls. A chosen band of 1500 cavalry, and 500 infantry, were cut to pieces in attempting to force their way through the besiegers. The Seraskier, who had retired to the citadel, did not surrender till every thing around him was in flames. The number of prisoners, including the inhabitants, amounted to 11,749, the remains of a population of 30,000, the rest of whom perished during the siege. Population 8200. East Long. 29° 57', North Lat. 47°. (H)

BENDER ABASSI. See GOMBROON.

BENDER MASSIN, or BANJAR MASSIN. See BANJAR MASSIN.

BENDER RIGK, BUNDARIK, or RIK, is a city of Persia, situated on an arm of the Persian Gulf, in the province of Kerman. It is surrounded with walls, and is the capital of a petty state, which comprehends several other places in Kermesir. "The Arabs of this principality," says Niebuhr, "are chiefly addicted to a sea-faring life; the Persians inhabiting its back parts are husbandmen. The reigning family of Bender-Rigk are of the Arabian tribe of Beni-Saab, and are originally from Oman; but the grand-father of the present prince having become a Shute, and married a Persian lady, their family are no longer counted by the Arabs among their genuine nobility." The cruelties, and history of Mir Mahama, which are not worthy of being recorded, will be found in Niebuhr's *Travels*, Sect. xxiii. chap. iv. East Long. 51° 17', North Lat. 29° 30'. (Q)

BENEDICTINES, an order of monks, instituted A. D. 529, by Benedict of Nursia, from whom they had their name. The object of the founder was, to establish an order which should be distinguished by the mildness of its discipline, and the regularity of its members; and which should afford greater opportunities of piety, and of usefulness, than any of the existing orders. His rule of discipline was not ill calculated to produce these advantages, had not the inherent defects of monachism counteracted its operation, and defeated its salutary tendency. So convinced was he of the efficacy of his plan, that those who were admitted into the order were solemnly bound to preserve its rules

inviolable, and not to alter them by any kind of modification. As the existing orders in the west had been degraded by manifold corruptions, the rule of Benedict soon came into great celebrity. In France, Italy, England, and Germany, it soon arrived at the highest pitch of glory: the other orders continued to maintain a languishing existence, till about the ninth century, when the Benedictine absorbed all the other religious societies, and held unrivalled the reigns of monastic empire. The monks considered the predominating influence of their order, as an attestation from heaven in favour of its sanctity and usefulness. This was all fair; but it was not thought sufficient: and they must have their miracles to support the credit of their order. In one sense, perhaps, they were right; for the prevalence of any of the monastic orders could only arise from the miraculous ignorance and stupidity which had overwhelmed Europe.

But this celebrated order had scarcely reached the zenith of its glory, when it began to exhibit the symptoms of decline. Wealth has truly been the root of all evil, in all the monastic institutions. In spite of the vows of poverty and mortification, which the initiated had solemnly made, they began to think that it was but reasonable, to appropriate to their own convenience some of that superstitious wealth, which the mistaken liberality of the public had conferred, and as soon as this rule was adopted, the rule of St Benedict was but little heard of. To use the words of Mosheim, "they sunk into luxury, intemperance, and sloth, abandoned themselves to all sorts of vices, extended their zeal and attention to worldly affairs, insinuated themselves into the cabinets of princes, took part in political cabals, made a vast augmentation of superstitious rites and ceremonies in their order, to blind the multitude, and supply the place of their expiring virtue; and, among other meritorious enterprises, laboured most anxiously to swell the arrogance, by enlarging the power and authority of the Roman pontiff." Vol. ii. p. 118.

In short, it appears that they fell from the high rank which they had so long held in the estimation of the world, by the same means which afterwards hurled their patron, the Pope, from the seat of his authority and power; by presuming a little too much on the indulgence and simplicity of mankind. But whatever might be the cause of their decline, it appears, that about the middle of the tenth century, they stood in vehement need of reformation. This regeneration was attempted with considerable success by Odo, Abbot of Clugni, who, in endeavouring to reform the order, in a great measure superseded it by one of his own, and the *order of Clugni* soon became almost as famous over Europe as had been that of Benedict.

We would refer such as wish for farther information on this subject, to Milner's *History of Winchester*. (v)

BENEDICTION, in a general sense, is the act of blessing, or of praying to God for a divine blessing; but it is also used to signify praise, or a grateful acknowledgment of blessings received. Hence it has been applied to the act of saying grace both before and after meals. Among the Jews, benedictions were of various kinds. The original institution of them is to be found among the patriarchs. From the time that God entered into covenant with Abraham, and promised extraordinary blessings to his posterity, it was custo-

mary for the father of each family, some time before he died, to call together his children, and inform them, according to the knowledge which it pleased God then to give him, how, and in what manner, the divine blessing conferred upon Abraham was to descend among them. Upon these occasions, the patriarchs enjoyed a divine illumination, which enabled them to look back into futurity; and, under its influence, their benediction was deemed a prophetic oracle, foretelling events with the utmost certainty, and extending to the remotest period of time. These blessings descended to the eldest son of the family, and to his latest posterity, unless forfeited by their bad behaviour. To him belonged the birth-right, or right of primogeniture, by which he could claim the particular blessing of his dying father; and to him, and to his posterity, belonged the blessings of the covenant which God made with Abraham, that from him the promised Messiah should descend. Solemn blessings were also pronounced, that is prayed for, by the priests upon the people. "On this wise," says Moses to Aaron, "ye shall bless the children of Israel, saying unto them, the Lord bless thee, and keep thee: the Lord make his face to shine upon thee, and be gracious unto thee: the Lord lift his countenance upon thee, and give thee peace." The prophets also, and other inspired persons, frequently blessed the servants and people of God, of which many instances are to be found in the Psalms. Among the Jews too, there was a ceremony which they called the cup of blessing, and which was observed in this manner. The master of the house having asked a blessing, took a cup full of wine, tasted it, and handed it to the person next to him, who did the same till it had gone round the whole company. This was called the blessing of the wine. Next followed the blessing and breaking of the bread, which was in the same manner distributed among the guests. When the repast was ended, he returned thanks in name of the whole company. In this cup of thanksgiving, they blessed God for their present refreshment, for their deliverance out of Egypt, for the covenant of circumcision, and for the law given by Moses; and prayed that God would be merciful to his people Israel, that he would send the prophet Elijah, and that he would make them worthy of the kingdom of the Messiah. Under the name benediction, the Jews also include presents sent by one friend to another, probably because accompanied with blessings or good wishes. Even their friendly salutations partook of the nature of benediction. "God be gracious unto thee, my son," were the words with which Joseph received Benjamin. In any country of Europe, this would be considered as a benediction; but in the East, it is used merely as a salutation, similar to those offers and assurances of friendship which we make, when we first address or take leave of a friend. This accounts for the reason why the scriptures so often call the salutations, and farewells of the East, by the term *blessing*. Various benedictions are still in use among the Jews, the form and order of which are prescribed by the Talmud.

Among the Jews, as well as among Christians, benedictions were conferred by the imposition of hands, to which the latter afterwards added the sign of the cross. Hence in the Romish church, benediction is used to denote the sign of the cross, as made by a bishop, which is supposed to confer some grace or blessing upon the people. The custom of receiving benedictions, by bow-

ing the head before the bishop, is very ancient; a mark of religious respect to which even emperors deigned to submit.

Benediction is also used for that religious ceremony, by which a thing receives a sacred character and use. The spirit of superstition, in the church of Rome, has multiplied these religious rites to an astonishing degree, in order to strike the imagination, and captivate the minds of the multitude. In general they are performed by aspersions of holy water, signs of the cross, and prayers suitable to the nature of the ceremony. Whoever wishes to see a particular account of them, may consult the book of ecclesiastical ceremonies, published in the pontificate of Pope Leo X., and father Martene's work on the rites and discipline of the church. The Pope began all his bulls with, *Salutem et apostolicam benedictionem.* (A. F.)

BENEVENTO, a city of Italy, in the kingdom of Naples, and capital of the Principato Ultra, is situated at

the junction of the Sabato and Calore, at the extremity of a hill which lies between these rivers. This town is celebrated for containing several beautiful remains of Roman sculpture and architecture. The Porta Aurea, which forms one of the entrances to the city, is an elegant monument of white marble, of the Composite order, consisting of an arch whose span is 20 palms, and height 35. It was built by Trajan about the year of Christ 114, and commemorates, on basso relievos, the battles of the Dacian war. There is scarcely a wall in the upper town of Benevento that is not composed of the precious ruins of ancient tombs, altars, and pillars of entablatures. The cathedral, built in the 6th century, has no claim to particular notice. An Egyptian obelisk of red granite, loaded with hieroglyphics, ornaments the court of the cathedral. Population, 10,000. East Long. 14° 38', North Lat. 41° 7'. See Swinburne's *Travels in the Two Sicilies*, vol. ii. p. 336. (π)

BENGAL.

BENGAL, the most eastern province of Hindostan, and one of the fifteen *Soubahs*, into which that empire was divided in the reign of Acbar, is situated on each side of the river Ganges. It is bounded on the north, by Asam, Bootan, and Bahar; on the south, by Orissa, and the bay of Bengal; on the west, by Bahar, Berar, and Orissa; and on the east, by a range of mountains, by which it is separated from Gassay, Aracan, and the Birman dominions. Its greatest length, from east to west, is about 720 miles; and its greatest breadth, from north to south, about 300; extending from 21° 30' to 26° 40' N. Lat., and from 86° to 92° 30' E. Long. "The natural situation of Bengal is singularly happy with respect to security from the attacks of foreign enemies. On the north and east, it has no warlike neighbours; and has, moreover, a formidable barrier of mountains, rivers, or extensive waters, towards those quarters, should such an enemy start up. On the south is a sea-coast, guarded by shallows and impenetrable woods, and with only one port (and even that of difficult access) in an extent of 300 miles. It is on the west only, that any enemy is to be apprehended; and, even there, the natural barrier is strong; and with its population and resources, aided by the usual proportion of British troops, in addition to the Sepoy establishment, Bengal might bid defiance to all that part of Hindostan, which might find itself inclined to become its enemy." Rennel's *Memoir*, p. cxv.

As the province of Bengal lies almost entirely within the torrid zone, and borders on several extensive sandy wastes, it is subject to great extremes of heat; and is accounted more unhealthy to Europeans, than any other British settlement in India, except that of Bencoolen. The south east quarter especially, in which the town of Calcutta is situated, and which is a flat marshy country, was deemed at first almost as destructive as Batavia: and at one period, when the whole Europeans resident in Calcutta did not exceed 1200, 400 burials were numbered in six months. The great and general cause of disease, in this country, is an excess of bile, which occasions fevers, dysentery, inflammation of liver, with a long train of nervous affections. These diseases are most prevalent in the months of Septem-

ber and October, are generally very rapid in their progress, and chiefly attack those, who are newly arrived from Europe; but the introduction of a more temperate and regular mode of living, and the more intimate acquaintance which the medical practitioners have acquired with the peculiar diseases of the country, have contributed to render their attacks less frequent and fatal. The varieties of disease are not numerous; their treatment is extremely uniform; almost every stage has its appropriate remedy; and no where are the prescriptions of the physician more certainly followed with success. By cutting canals, by draining the offensive marshes, and by clearing the ground of trees and jungle, the climate has been already, and may be expected to be still farther, improved; but with all that can be done, it must always prove a severe trial to every European constitution. Even those, who are not materially injured by its influence, are scarcely capable of any exertion; and during the hot season, particularly, it is not uncommon to find the whole officers of a battalion, except one or two individuals, utterly unfit for duty; and this without any extraordinary or alarming complaint. This insalubrity is supposed to be owing, in a great measure, to the prevalence of the hot winds, which are occasionally loaded with sandy particles, which are peculiarly pernicious to persons asleep, and frequently so suffocating as to be almost insupportable by the natives themselves; but principally to the stagnate waters and putrescent substances, which are left upon the flat surface of the county, by the frequent inundations of its rivers. The seasons are here commonly distinguished by the terms hot, cold, and rainy; but the natives subdivide them into six, comprizing two months in each. The hot season continues from the beginning of March to the end of May; and during this period, the thermometer very frequently rises to 100, sometimes even to 110; but in the middle parts of Bengal the extreme sultriness of the weather is greatly moderated by occasional thunder storms, accompanied with rain or hail, driven by sudden gusts of north-west wind; while in the eastern districts, milder showers of rain are still more frequent, and peculiarly refreshing to the heated atmosphere; but in the districts contiguous to Bahar,

a parching wind from the west, continues during the greater part of the season. The rainy season commences in June, and lasts till October; and during the two first months, the rain is so heavy and constant, that frequently three, four, and even five inches of water have fallen in one day; but during the two last months, there are frequent intermissions of the rain, the weather is rather close and sultry, and thick unwholesome fogs prevail. The cold season continues from November to February, during which period northerly winds prevail, the sky is clear and unclouded, and the weather generally pleasant to an European constitution. The dews during the night are abundant and penetrating, and greatly assist the progress of vegetation; while, in the more mountainous districts, even frost and extreme cold are frequently experienced.

The general aspect of Bengal is that of a champaign country, intersected by numerous rivers, and surrounded by chains of lofty mountains. That part of the Delta through which the Ganges expands his branches, as he approaches the sea, is the lowest district in the province, and seems as if newly emerging from the waters. It is called the *Sunderbunds* or woods; lies between the river Hoogly and Chittagong; and is equal in extent to any of the three kingdoms of which Great Britain is composed. It is a labyrinth of creeks and rivers, of jungle and stagnated water, a dreary uninhabited waste, infested by boars and tygers; but its numerous canals are so disposed, as to form a complete inland navigation throughout the Lower Delta. It abounds in quantities of salt, equal to the whole consumption of Bengal and its dependencies; and it furnishes an inexhaustible store of timber for fire-wood, domestic uses, and boat-building. Some attempts have been made, and with considerable prospect of success, to clear and cultivate this inhospitable tract; but, as land in every part of India is yet very imperfectly occupied, there is no sufficient stimulus to make new acquisitions; and, as it is deemed by some a matter of policy to have such an extensive desert lying between our possessions, and the only point of attack from an European enemy, there is not much encouragement given to the cultivation of the *Sunderbunds*. Within the boundaries of the province, and particularly in the south-west angle, and on the north of the Ganges, are to be found more elevated tracts of land, remarkable for picturesque scenery, and for the neat habitations of the peasantry. These upper regions, however, which are not liable to inundation, and which were formerly called *Barendra*, are of very inconsiderable extent, and of very inferior estimation in the views of commerce and finance. The principal division of Bengal, and that which is most valuable for its produce and manufactures, is an extensive and uninterrupted level, through which the Ganges and *Burrampooter* slowly roll their immense volumes of water, and which they annually overflow in the rainy season.

The general soil of Bengal is a congeries of clay, mixed with a considerable portion of sand, fertilized by various salts, and by immense quantities of decayed vegetable and animal substances. It is a rich, blackish mould, extremely loose in its texture, extending to a very great depth, (to six, fourteen, and even to twenty feet,) lying on a bed of sand, interspersed with shells and rotten wood, affording every indication of a country gained from the sea, and formed by deposition from the waters of the rivers, and of the annual inundations. In proof of this supposition it may be mentioned, that

similar processes are continually affected by the rivers bursting from their beds; and that there are frequently found at the depth of 20 or 30 feet the wrecks of boats, with their anchors and other implements, which seem to have been sunk in some remote period, when the soil was lower, or when this vast plain formed a part of the sea.

These inundations, to which the province of Bengal in a manner owes its origin, and upon the due proportion of which its prosperity annually depends, form the most interesting object of attention to the natives, and must hold a prominent place in every account of the country. The following description of these periodical floods, the most distinct with which we are acquainted, and the least capable of abridgment, is submitted to our readers in the identical words of the eminent geographer, from whose pen it proceeded. The Ganges "appears to owe its increase as much to the rain water, that falls in the mountains contiguous to its source, and to the sources of the great northern rivers, that fall into it, as to that which falls in the plains of Hindostan; for it rises fifteen feet and a half out of thirty-two (the sum total of its rising) by the latter end of June; and it is well known, that the rainy season does not begin in most of the flat countries till about that time. In the mountains, it begins early in April; and by the latter end of that month, when the rain water has reached Bengal, the rivers begin to rise, though by very slow degrees; for the increase is only about one inch per day for the first fortnight. It then gradually augments to two and three inches, before any quantity of rain falls in the flat countries; and, when the rain becomes general, the increase, at a medium, is five inches per day. By the latter end of July, all the lower parts of Bengal, contiguous to the Ganges and *Burrampooter*, are overflowed; and form an inundation of more than a hundred miles in width, nothing appearing but villages and trees, excepting very rarely the top of an elevated spot (the artificial mound of some deserted village) appearing like an island. But the inundations in Bengal are as much occasioned by the rain that falls there as by the waters of the Ganges; and as a proof of it, the lands in general are overflowed to a considerable height, long before the bed of the river is filled. It must be remarked, that the ground adjacent to the river bank, to the extent of some miles, is considerably higher than the rest of the country: and serves to separate the waters of the inundation from those of the river, until it overflows. This high ground is in some seasons covered a foot or more; but the height of the inundation within varies, of course, according to the irregularities of the ground; and is in some places twelve feet. Even when the inundation becomes general, the river still shews itself, as well by the grass and reeds on its banks, as by its rapid and muddy stream; for the water of the inundation acquires a blackish hue, by having been so long stagnant, among grass and other vegetables; nor does it even lose this tinge, which is a proof of the predominancy of the rain-water over that of the river; as the slow rate of the motion of the inundation, (which does not exceed half a mile per hour,) is of the remarkable flatness of the country. There are particular tracts of land, which, from the nature of their culture, and species of productions, require less moisture than others, and yet, by the lowness of their situation, would remain too long inundated, were they not guarded, by dikes or dams, from so copious an inundation as would otherwise happen, from the

great elevation of the surface of the river above them. Those dikes are kept up at an enormous expense; and yet do not always succeed from want of tenacity in the soil of which they are composed. It is calculated, that the length of those dikes collectively amounts to more than a thousand English miles. Some of them, at the base, are equal to the thickness of an ordinary rampart. One particular branch of the Ganges (navigable only during the rainy season, but then equal to the Thames at Chelsea) is conducted between two of these dikes for about seventy miles: and when full, the passengers in the boats look down on the adjacent country, as from an eminence. During the swollen state of the river, the tide totally loses its effect of counteracting the stream: and, in a great measure, that of ebbing and flowing, excepting near the sea. It is not uncommon for a strong wind, that blows up the river for any continuance, to swell the waters about two feet above the ordinary level at that season, and such accidents have occasioned the loss of whole crops of rice. A very tragical event happened at Luckipour in 1763, by a strong gale of wind conspiring with a high spring tide, at a season when the periodical flood was within a foot and a half of its highest pitch. It is said, that the waters rose six feet above the ordinary level. Certain it is, that the inhabitants of a considerable district, with their houses and cattle, were totally swept away; and, to aggravate their distress, it happened in a part of the country, which scarcely produces a single tree, for a drowning man to escape to. Embarkations of every kind traverse the inundation; those bound upwards, availing themselves of a direct course and still water, at a season when every stream rushes like a torrent. The wind, too, which at this season blows regularly from the south-east, favours their progress; inasmuch, that a voyage, which takes up nine or ten days by the course of the river, when confined within its banks, is now effected in six. Husbandry and grazing are both suspended; and the peasant traverses in his boat those fields, which, in another season, he was wont to plow; happy, that the elevated site of the river banks places the herbage they contain within his reach; otherwise his cattle must perish." "The inundation is nearly at a stand for some days preceding the middle of August, when it begins to run off; for although great quantities of rain fall in the flat countries, during August and September; yet, by a partial cessation of the rains in the mountains, there happens a deficiency in the supplies necessary to keep up the inundation." "The decrease of the inundation does not always keep pace with that of the river, by reason of the height of the banks; but after the beginning of October, when the rain has nearly ceased, the remainder of the inundation goes off quickly by evaporation, leaving the lands highly manured, and in a state to receive the seed, after the simple operation of plowing." Rennel's *Memoir*, p. 548, &c.

The intense heats which succeed the rainy season, and which act upon the soil when full of moisture, produce, in Bengal, a luxuriance of vegetation which is unknown in any other country in the world. The lands are easily cultivated, and yield abundant crops without any other manure than what has been deposited by the waters of the inundation. The principal food of the natives, and, consequently, the principal object of the husbandman, is rice; but very good wheat and barley, though much smaller and lighter than in Europe, is also produced. A great variety of different kinds of pulse is

raised during the intervals of attention to the white grains, such as pease, chiches, pigeon pease, kidney beans, &c.; and these constitute a very valuable article in Bengal husbandry, as they require very little culture, and thrive readily on the poorer soils. Maize, millet, panic, and other small grains, which are chiefly the food of the poorer classes, are very generally sown, especially in the hilly regions and western districts; and there is a very extensive culture of mustard, sesamum, lintseed, and palma christi, to supply the vast consumption of oil by the natives of the country. The plough of Bengal is drawn by a single yoke of oxen, guided by the ploughman himself; but three pair of oxen are assigned to every plough, and these relieve each other till the daily task be completed. Several ploughs in succession deepen the same furrows, or rather scratch the surface, as it has no contrivance for turning the earth, and the share has neither width nor depth to stir a new soil. A second ploughing crosses the first, and a third is sometimes given diagonally to the preceding. These frequently repeated, and followed by the substitute for the harrow, which is generally nothing more than the branch of a tree, pulverise the surface, and prepare it for the seed. For the extirpation of weeds after the crops have risen above the ground, the labourers employ a short-handed spade, and place themselves at their work in a sitting posture. There are two seasons of reaping in the year; one in April, called the little harvest, which consists of the smaller grains; and another, called the grand harvest, which is wholly of rice, though in some places three crops of this grain are raised in one year. But nothing can be conceived more tedious and injudicious than the mode of reaping. A mixture of different crops is frequently sown together in the same field; and, as these ripen in succession, the husbandman must either gather them singly, which occasions great destruction to the later plants by their being repeatedly trodden down, or must wait till he can reap the whole at once, which causes an equal loss in the more early grains by over ripeness. The corn of every description, after being reaped, is carelessly piled up without any defence from the weather, to be trodden out by the cattle, or threshed by the staff of the husbandman at his convenience; and the grain, after being winnowed in the wind, is stored in jars of unbaked earth, and baskets made of twigs or grass, or is hoarded above ground in round huts, the floor of which, on account of the dampness of the climate and the moisture of the soil, is raised a foot or two above the surface.

With an excellent soil and climate, with almost every variety of cultivated grains, and with a competent number of labourers at a small expense, the imperfection of Bengal husbandry is great beyond what might have been expected. Sufficient attention is not paid to the most proper periods of sowing. No care is employed in selecting the best varieties of each kind of grain. The most valuable crops are not steadily preferred in cultivation. The implements are scanty and incompetent. The rotation of crops is not understood. The dung of the cattle is dried for fuel; and, except in cultivating the sugar cane, mulberry, tobacco, and poppy, no manure is applied. The lands are not duly fallowed and cleaned. Drill husbandry, though known in the more remote countries, is not practised in this province, even in the culture of the sugar cane. There are no inclosures in the country; no capital among the agriculturists; and no roads kept in repair. The former unset-

tled state of the country exposed the cultivators of the soil to perpetual pillage and oppression. The husbandman has at no time any thing resembling a secure lease, or permanent interest in the fields. Even the genial nature of the climate, and remarkable fertility of the soil, have contributed to prevent that exertion of ingenuity and application of labour, which, in more barren regions, and under more unpropitious skies, have brought the cultivation of the soil to the higher state of improvement. All these circumstances have operated so strongly as obstacles to the progress of agriculture in Bengal, that this most useful and first practised of human arts must be considered as still in its infancy, or as having greatly degenerated.

There is one circumstance, however, peculiar to the lower districts of this province, which frequently renders abortive the utmost skill and diligence of the husbandman; viz. an excess or a deficiency in the annual inundations. When their increase is gradual, the growth of the rice keeps pace with the rise of the waters, is thus always above its surface, and is frequently reaped in boats; but when the inundations rise too rapidly, or much above their ordinary level, the rice is overtopped and destroyed by the flood. The immense and expensive dykes mentioned above, and which are intended to guard against such disastrous occurrences, are frequently found to be very feeble barriers against the gathering stream of the Ganges. Its huge volume of water, bursting through the strongest, or rising over the highest, of its banks, spreads far and wide over the level plains, sweeps away every thing in its course, and covers the richest fields with a bed of barren sand. The fatal effects of a dry season are still more extensive and destructive; and in order to provide some source of relief, under the pressure of such a calamity, numerous reservoirs, called *tanks*, of an oblong square shape, frequently more than an acre in extent, are constructed throughout the country. These being filled with water in the rainy season, afford the inhabitants, during the dry period, a supply of water for domestic uses, superior in quality to that of the Ganges; and, by means of irrigation, form a grand instrument of fertilizing the parched fields. In the higher parts of Bengal, this practice is, at all seasons, an indispensable requisite in husbandry; and as it is there *always* necessary, it is more effectually and industriously administered. "Towards the end of the rains, the fields are well ploughed in the ordinary manner; but, before sowing the seeds, they are divided into little square plots, resembling the chequers of a backgammon table. Each square is surrounded with a shelving border, about four inches high, capable of containing water. Between the square chequers, thus constructed, small dykes are formed for conveying a rivulet over the whole field. As soon as the water has stood a sufficient time in one square to imbibe moisture, it is let off into the adjoining one, by opening a small outlet through the surrounding dyke. Thus one square after another is saturated, till the whole field, of whatever extent, is gone over." (Tennant's *Indian Recreations*, vol. ii. p. 167.) In the flat countries, however, these means of remedying the occasional deficiencies in the fall of the rains, and the flow of the rivers, are not provided with sufficient care; and the reservoirs, water courses, &c. are more generally in a progress of decay, than of improvement.

But no possible precautions can prevent the failure of the crops in unfavourable seasons; and as, in conse-

quence of the feeble and scanty husbandry practised in India, there is very rarely, even in plentiful years, any surplus produce, to guard against the effects of a scarcity, the inhabitants of that country, which is, perhaps, the most fertile in the world, are more frequently, than any other people, the victims of absolute want. Even the province of Bengal, the most fruitful in India, was often visited in former times with the same calamity; of which a very dreadful instance occurred in the year 1770, in consequence of an unusual drought. When the granaries of the Nabobs and of the Company began to fail, and rice could no longer be supplied to the poorer classes, thousands of them expired of hunger in the fields, and in the streets of Calcutta. Their dead bodies, mangled by dogs and vultures, tainted the air, and threatened a pestilence, in addition to the miseries of famine. About 100 persons were daily employed by the Company in throwing the dead bodies into the river; which corrupted the water, and rendered the fish unwholesome nourishment. The hogs, ducks, and geese, also, fed so much upon human carcasses, that the only animal food which could be used was mutton; while that, on account of the dry season, was so extremely small, that a quarter of a sheep scarcely weighed a pound and a half. By the foresight, however, of Europeans, the benevolent exertions of the East India government, and the peace and protection enjoyed by the husbandmen of this province, the recurrence of such an evil has been in a great measure prevented, its duration shortened, and its pressure alleviated.

The most important of the other vegetable productions of Bengal, besides pulse and grain, are tobacco, indigo, cotton, mulberry, poppy, guavas, plantains, pomegranates, limes, oranges, pomegranates, melons, pine apples, the banyan tree, the pisang or banana, the cocoa nut palm, which supplies a manufacture of cordage, called *coir*; the sugar cane, which thrives in every district, and might be still more successfully cultivated in all; the betle vine, a species of pepper, raised in almost every village; the mango tree, the fruit of which is in the highest estimation, and is almost universally used during the hot months; the date tree, which grows every where, and which yields a sweet liquid of an intoxicating quality, from which sugar is sometimes extracted; the suri tree, which also affords, by incision of the stem, a clear, sweet, inebriating juice, which when sour is sometimes used instead of vinegar; the areca, in large plantations, the wood of which is tough as whalebone, and its nut a useful article of food; and the bassia, abounding in the hilly countries and poorer soils, the corols of which are esculent and nutritious, while its oil is a frequent substitute for butter. In the gardens are cultivated most of the vegetables of other climates fit for culinary purposes. The potatoe, particularly, has been introduced with considerable success; and as it thrives best in the dry seasons, which are destructive to the rice crops, it might be the means, if cultivated to a sufficient extent, of placing the lower classes in Bengal almost beyond the reach of famine.

The various sorts of flowering trees and shrubs, which either grow wild, or thrive with little care, are too numerous to be mentioned in this place; but we may notice, as the most remarkable and beautiful, the *chulta*, the flower of which is at first a hard green ball, on foot stalks about four inches in length. The calyx, after the ball has opened, is composed of five round, thick, succulent leaves, and the corolla of the same number of fine

white petals. After continuing only one day, the corolla drops, and the ball closes; while a succession of these opening and shutting flowers continues during the space of several months. A tall tree, called the *tatoon*, used in bordering the walks, the leaves of which are of a deep shining green colour, and the fruit resembling an olive, with a kernel like the date. A large spreading tree, called *russa*, which has a peculiar rich and beautiful appearance when in full bloom, as it is then covered with flowers of a bright crimson, or of a bright yellow, or of some intervening shade between these two colours. Of this remarkable tree, however, it is said, that there are only two plants known in Bengal; one of which is in the neighbourhood of Calcutta, and the other near the Dutch settlements. It has been mentioned, as one cause of its scarcity, that the ants and other insects are so fond of its seed, that not one pod can be found entire and uninjured.

Wild boars, bears, wolves, foxes, jackalls, hyænas, leopards, panthers, lynxes, hares, deer, zebres, wild buffaloes, antelopes, apes and monkeys, elephants, tygers, are natives of Bengal. The foxes are feeble and slender, the hare and deer very inferior to those of Europe, and the venison in general lean and insipid. The dogs are generally of the cur species, with sharp erect ears and pointed tails. There is found in the eastern districts an undescribed animal called the *gyal*, which may be placed between the domestic bull and the buffalo. The rhinoceros with one horn, abounds in the isles of the Ganges. But the royal tyger of Bengal, is most of all worthy of particular notice; it seems to have been known to the Romans, and is distinguished by Seneca the poet by the appellation of *Gangetica tigris*. This animal is sometimes five or six feet in height, of such enormous strength as to carry off a large bullock, and able to clear a hundred feet at one spring. The horses, chiefly used in Bengal by the Grandees and Europeans, are of the Persian or Arabian breed, and are procured at an immense value. The native horses are thin, ugly, and ill shaped animals, tolerably active; but in their best state, not equal to the Welsh and Highland ponies. Bengal is more defective in its breed of cattle, than most other parts of India. The pastures are overstocked; and the black cattle and hogs are barely kept alive: herds of the former may often be seen in such a starved state, that not one of them would weigh against a good English sheep. The goats and sheep thrive better; but the latter are very small, of a lank figure, black or dark grey colour, with coarse, thin, and hairy wool.

Game, poultry, and water fowl of all descriptions, are found in the greatest abundance in Bengal. Ducks, particularly, are here in great variety and excellence; and the common domestic fowl of Europe, run wild in the woods, and are called therefore the jungle fowl. In consequence of the humanity of the natives towards the lower animals, the crow, kite, mino, and sparrow, hop about the dwellings of the Bengalese with entire familiarity; and even in the houses of the English, pilfer from the dishes of meat, as they are carried from the cook-room to the hall. A large species of stork, ludicrously termed the *adjutant*, from his erect posture and military strut, stalks at his ease at the side of the natives, and devours abundance of toads, lizards, serpents, and insects. Among the feathered tribes, may be particularly mentioned, the argill or hurgill, a species of ardea, which is very large and ravenous, and which is held in great veneration by the Brahmins.

The inland commerce of Bengal is carried on chiefly with Thibet, Agra, and Delhi. The principal articles are silks, calicoes, muslins, salt-petre, opium, sugar, indigo, gum lac, with a variety of piece goods, which pass almost entirely through the agents of the company. The exportation of grain from the corn countries, and the importation of salt, constitute the greater part of this trade in the hands of the natives. The importation of cotton from the western provinces, and the exchange of tobacco and betel nut, form almost the whole supply of internal consumption. Some part of this merchandise is transported by land carriage, which is commonly performed by oxen, sometimes by the small horses of the country, and rarely by buffaloes; because though those animals are both stronger and more docile than oxen, they are less easily maintained. The magnificent causeways, formerly constructed by the native princes, are now fallen into decay. The country affords no substantial materials for the formation of highways; and, except in the neighbourhood of military stations, there are no roads sufficient to admit the use of wheel carriages. These disadvantages, however, are abundantly compensated by the facility with which internal navigation is conducted. So completely are the various branches of the Ganges and the Burrampooter diffused over the flat country, that scarcely any part of this large province is above twenty-five miles distant from a navigable river. The wood, salt, and provisions of many millions of people, are conveyed along these channels by 30,000 boatmen, who are the most laborious and hardy race in India. "These rivers are in a state of tranquillity, from the time of the change of the monsoon in October to the middle of March, when the *north-westers* begin in the eastern parts of Bengal, and may be expected once in three or four days, until the commencement of the rainy season. These *north-westers* are the most formidable enemies that are met with in the inland navigation, being sudden and violent squalls of wind and rain, and though of no long duration, are often attended with fatal effects if not carefully guarded against; whole fleets of trading boats having been sunk by them almost instantaneously. They are more frequent in the eastern, than in the western part of Bengal; and happen oftener towards the close of the day, than at any other time. As they are indicated some hours before they arrive, by the rising and very singular appearance of the clouds, the traveller has commonly time enough to seek a place of shelter. It is in the great rivers alone, that they are so truly formidable; and that about the latter end of May and beginning of June, when the rivers are much increased in width." "During the long interval between the end of the rainy season and the beginning of the north-westers, one proceeds in security with respect to weather; and has only to observe a common degree of attention to the piloting the boat clear of shallows and stumps of trees." "From the beginning of November to the latter end of May, the usual rate of going *with* the stream is 40 miles in a day of 12 hours; and during the rest of the year from 50 to 70 miles: The current is strongest, while the waters of the inundation are draining off; which happens in part of August and September." "Seventeen or twenty miles a day, according to the ground, and the number of impediments, is the greatest distance that a large *budgerow* can be towed *against* the stream during the fair season; and to accomplish this, the boat must be drawn at the rate of 4½ miles per hour, through the water, for twelve

hours." (Rennel's *Memor. &c.*) The vessels, employed in this navigation, are variously constructed, according to the nature of the rivers on which they are employed; and are of various sizes, from eight to twenty-four oars. Some have cabins 14 feet wide, and proportionably long; and draw from 4 to 5 feet water: the larger boats upon the Ganges carry from 300 to 600 mauns.

The maritime trade of Bengal, as far as it is managed by the natives, was never so extensive as the inland. The principal part of it is conveyed by the way of Calcutta, a district of considerable extent, situated upon a navigable river, a little below the most western mouth of the Ganges. From Balasore, which is its principal port, a traffic in rice, cottons, and silk is carried on with the Maldives in exchange for cowries; and with the country of Asam by supplying it with great quantities of salt, receiving in payment, gold, silver, ivory, gum lac, and silk. These two branches of maritime commerce have been entirely abandoned to the natives, for particular reasons; namely, the fatality of the climate of the Maldives to Europeans, and the regulations of the sovereign of Asam, restricting the right of importation into his dominions solely to the Bengalese.

A very considerable branch of trade is carried on by the Europeans in Bengal, in furnishing the rest of India with opium, which is produced in Patna, on the Upper Ganges, in greater abundance than in any other part of the world, and which is exported in an unprepared state, scarcely possessing the tenth part of the virtue of purified opium. Rice is exported to Ceylon, cottons to Malabar, and silk to Surat; from which is usually brought, in return, a considerable quantity of raw cotton, to be employed in the Bengal manufactures. Rice, gum lac, and cottons, are sent to Bassora, receiving in exchange, dried fruits, rose water, and gold; rice and sugar, to the coast of Coromandel, generally paid for with specie; a variety of rich merchandize to Arabia, receiving in return gold and silver. These branches of trade, though passing chiefly through the hands of Europeans, and carried on under their protection, are not always solely on their account, but frequently in conjunction with Gentoo, and especially Armenian merchants, great numbers of whom, since the revolutions in Persia, have settled upon the banks of the Ganges.

The principal manufactures and articles of trade which Bengal could furnish to the merchant in great abundance and perfection, are cotton piece goods of various descriptions; calicoes, a name applied to several kinds of cloth, to which no English names have yet been affixed; pack-thread, woven into sack-cloth, and employed as clothing by the mountaineers; cotton canvass, flannel, and blankets; dimities of various kinds and patterns, and cloths resembling diaper and damask-linen; wove silk taffeta, plain and flowered; tissues, brocades, plain and ornamented gauzes; a mixed cloth of silk and cotton; filature silk, and tessa or wild silk; grain, sugar, tobacco, indigo, salt-petre, hides, gums, liquorice, ginger, and a great variety of medicinal and dyeing drugs. The articles which are most in demand in Bengal, are japan copper, tin, lead, pewter, sandal and sapan wood, all kinds of spices, and a variety of European commodities.

Bengal and its dependencies contain five large, and as many smaller cities; forty large towns, and a great number of smaller but not inconsiderable towns; the chief

of which are mentioned in the common maps of the country, and need not be enumerated here.

From the want of public registers, the amount of the population in the provinces of India cannot be very exactly ascertained; but various calculations, formed on different data, coincide in estimating the inhabitants of this presidency at more than thirty millions, of which Bengal Proper may be allowed to contain more than one-half. From the fertility of the soil, and the slender vegetable diet required by the natives, it has been computed, that on the same quantity of land in Bengal might be maintained four times the number of people that can be done in Great Britain; and that this province, if brought fully into a state of cultivation, could support more than double its present number of inhabitants. Of this population, about four-fifths consist of native Hindoos, and the remainder of Moguls. The Moguls are the descendants of those, who reduced the whole empire of Hindostan about three centuries ago, and were originally natives of Tartary. In the eastern districts of Bengal they are nearly as numerous as the Hindoos. They are of an olive colour, with features resembling the European. They are all Mahommedans, and hold the idolatry of the Hindoos in so great abhorrence, that, even under the protection of the East India Company, there are frequently very bloody feuds between these two classes of subjects. The Hindoos are slender, handsome, and well made, resembling Europeans in stature, of a dark brown colour, and sometimes a yellowish complexion, with hair black and uncurled. Most of them shave their heads; eradicate the hair from every part of their bodies; and go almost naked, with only a piece of linen round their middle; but those of a higher rank are accustomed to wear turbans, and a dress of white cotton, which reaches from the shoulders to the feet. The dress of the women consists of drawers, a loose coat, and a piece of cotton cloth thrown over the shoulders. Their head is uncovered, and their hair fastened up behind. They are fond of loading every part of their body, their hair, arms, legs, fingers, toes, and even nostrils, with all kinds of ornaments.

Four different European nations have formed establishments in Bengal for commercial purposes; viz. the English, French, Dutch, and Danes. The Danish settlement, Serampore, extends about two miles on the eastern banks of the Ganges, and is of very inconsiderable breadth; but, though a small territory, is of considerable value to the northern country. It is completely surrounded by the British dominions; has no fortifications except a small battery for saluting; and, on the late dispute with the northern powers, a party of Seapoys took possession of it without the least resistance. The French settlement of Chandemagore, and the Dutch one of Chinsura, are more extensive than the Danish; but, from the larger establishments kept up, have never been equally advantageous, and have always cost more than what they produced. When the East India Company appropriated to themselves the opium and salt-petre trade, to prevent any competition in the market, they agreed to allow a certain quantity annually to the Danes, French, and Dutch, at a specific price, on condition that they should not purchase any from the natives. These treaties, however, were not renewed with the French and Dutch, on the late peace; and they seem to have considered the surrender of their settlements, without that advantage, as a very useless gift. The English es-

established a commercial intercourse with Bengal at a very early period; and made a settlement on the river Ganges in the beginning of the 17th century. Their first factory was at the town of Hoogly; but in 1689 it was removed to Calcutta, which is about 26 miles farther down the river. By means of their fort and garrison, they protected, from the demands of the rajas, their trading vessels, which came down from Patna: but in the beginning of the 18th century, they obtained from Ferok-sere, great grandson of Aurung-zebe, a firman or grant, exempting their trade from all duties; and, while the company stood in need of protection against the native princes, this was regarded as their commercial charter in India. From the year 1742, they had frequent occasion to resist, by force of arms, the attacks of the Mah-ratta states, and of the nabobs of Bengal, till the famous battle of Plassey, in 1757, laid the foundation of their great power in that country. From that period they became the arbiters of the succession to the nabobship of Bengal; and in 1765 assumed the government of that province, receiving from the nominal Mogul, Shah Aulem, a grant of the revenues of Bengal, Bahar, and Orissa, on condition of paying 26 lacks of rupees (about 260,000*l.*) per annum. From this last date, Bengal, with its dependencies, have continued, without interruption, under the power of Great Britain; and, whatever diversity of opinion may exist, respecting the means by which that power was established, there can be no question that it has proved a most beneficial exchange to the natives. In all these provinces, the limits of order have uniformly extended with the progress of European dominion; for the space of half a century, (a circumstance unexampled in their history,) the calamities of war and of military depredation have been removed from their habitations; and they have enjoyed a degree of security in their persons and properties, at present unknown in any other part of Asia.

For other particulars, respecting the civil history of Bengal, its commercial connections with Great Britain, its government and revenues, the religion, language, manners and customs of its inhabitants, we refer our readers to the articles, INDIA, HINDOSTAN, EAST INDIA COMPANY, CALCUTTA, DACCA, GANGES, GENTOOS, HINDOOS, SEIKS, BRAHMINS, &c. See *Modern Univ. Hist.* vol. vi. Rennel's *Memoir of a Map of Hindostan*; Pinkerton's *Geography*. Tennant's *Indian Recreations*; *Thoughts on India*; *Remarks on the Husbandry, &c. of Bengal*. Valentia's *Travels*, vol. i. Pennant's *View of Hindostan. Asiatic Researches*, vol. x. (y)

BENGAL STRIPES, known also by the appellation of *Ginghams*, is one of the numerous varieties of the cotton manufacture which have been derived from Indian sources, and recently cultivated to very great extent in Britain. A very near relative of the writer of this article, was the first person who manufactured them to any extent, for the purpose of sale in Scotland; and their introduction in Lancashire, where they have been carried to a prodigious height, is still more recent. The Bengal or gingham, is a stout but generally rather fine fabric, of coloured striped cotton; and these stripes are sometimes crossed, with either similar or dissimilar stripes, by the woof, so as to form a check. The fabric of the Bengal stripes is generally designed to assimilate it to the heavier kinds of printed cottons used for women's apparel. A kind of a much denser fabric, and generally of much larger patterns, is also manufactured for hangings of beds, window curtains, sofa and chair

covers, and other kinds of domestic furniture. A great part of their excellence, when well manufactured, consists in strength of fabric and brilliancy of colour. Of the fabric, as it was first practised in Scotland, a very near idea may be had by taking about No. 32 for a 1200 reed, and, in this dense fabric, taking the proportion already stated, (as the squares of the reeds, so are the numbers of the warp,) the deviation from actual practice will not be great. The great expense of the Turkey red dye, which is the most prevalent colour, renders this article very expensive when the dyed warp is bold and coarse; and this circumstance has occasioned a very great falling off in the quality of these stuffs. The first expedient generally practised, is to make the coloured warp very considerably finer than the white; for, as the price of the dye, which is charged by the weight, greatly exceeds the original cost of the yarn, it becomes a great object in point of price, to save as much as possible in this respect. But, when the coloured warp is very disproportionately finer than the general body of the texture, besides the deterioration which the general fabric sustains, the brilliancy of the colour is inevitably lost; for the dyed warp is so sunk and concealed in the density of the general fabric, as only to produce a very faint effect. The whole fabric, particularly in the Lancashire goods, is sometimes also made extremely flimsy, and the defect is concealed from the superficial and ignorant observer, by the mode of dressing and finishing the goods, so as to give them an appearance of at least tolerable density of fabric; but the illusion is completely dissipated by the first wetting to which they are afterwards exposed. This mode of finishing consists merely in starching the cloth when bleached with a very thick mucilage, which completely insinuates itself into every vacancy between the threads; and then either dressing it with the paper or pasteboard cylinders, which will be described in the article CALENDER, or giving it high glazing with wax and the flint, as also described in the same article. In this state, when stiffened with the mucilage and well smoothed, it has a beautiful and glossy appearance; and really, in some respect, resembles the appearance of a sheet of well made writing paper; but whenever the starch, with which every part is fully saturated and impregnated, is dissolved by moisture, the thinness and poverty of the fabric is fully detected. The stripes which are made for furniture, requiring greater strength than those for garments, are more dense and close in the fabric than the others. If No. 24 of cotton yarn be taken for a 1200 reed, and other fabrics calculated by the same analogy as the former, something very near what takes place in common practice will be found. In the latter article, the colouring of the stripes is generally much heightened, by making that part of the texture of tweeled, instead of plain cloth. As the fast colours, such as purple, claret, Turkey red, blue, and buff, are generally employed, the fabric, if less susceptible of great ornamental variety than printed cloths, is generally very superior in the greater requisites of brilliancy and durability; and hence it is in higher estimation with those who study economy, and prefer durability to show. In an economical comparison with prints, among other advantages which loom woven stripes possess, is their being totally free from the excise duty of three-pence halfpenny per square yard, which attaches to the former; and, in coarse articles, forms a very heavy tax, being often above 20 per cent. *ad valorem*. (J. D.)

BENGO, a town of Africa, in the kingdom of Angola, and the capital of a province of the same name, situated on the river Bengo, and stretching along the west coast. This province was conquered by the Portuguese, who have cultivated considerable tracts of ground, which produce maize and manioc root in great quantities. Banana and bacoa trees also abound in this province. See Dapper's *Description de l'Afrique*. (j)

BENGUELA, a province of Angola, in Africa, stretching along the coast, the limits of which have not been accurately ascertained by geographers. This province was formerly governed by its own kings; but the incursions of the barbarous Giagas laid waste the country; and the protection of the Portuguese, who have built several forts along the coast, has not been able to restore it to its former importance. Near the Bay of Cows a great quantity of corn and beans are raised, and the inhabitants rear cattle of the best kind in great numbers. In the same part of the country, they gather a kind of odoriferous wood, called *kakongo*, which is held in high estimation. According to Marteniere, there are near the same bay excellent mines of copper. Another traveller maintains, that there are silver mines in the mountains, which have not yet been wrought.

The principal towns of Benguela are Old Benguela, situated upon a mountain; St Philip, or New Benguela; Mankikendo, and Kuschil. The chief rivers are Nika, St Francisco, Moreno, Farsa, Kuneni, and Canton-Belle. According to Dapper, the water of the last of these rivers is of a saline nature, and is collected into pits by the natives for the purpose of manufacturing salt. The mouth of this river, which is sheltered from the winds, is about sixteen feet deep. To the north of this river, the sea forms a gulf which is called Good bay by the Dutch, on account of its being an excellent watering-place. The climate of Benguela is very insalubrious. The mountainous districts swarm with wild beasts of various kinds. See Dapper's *Description de l'Afrique*. (H)

BENIN, sometimes called GREAT BENIN, the most extensive kingdom in Guinea, is bounded on the north by Gago, Nigritia, and a chain of mountains; on the south by the Gulf of Guinea; on the west by the kingdom of Ardra; and on the east by Mujak and Istana. Its principal river, the Formosa, divides itself into several branches, some of which are large and navigable streams. The banks of these streams are inhabited by various nations, governed by their respective kings, all of whom, except the sovereign of Awerri, are the slaves of the king of Benin.

Though this kingdom be extremely populous, its towns, or rather villages, are very distant from each other, not only in the interior, but also on the banks of the river, and on the coast. Next to the capital, its principal towns are Bododa, Arebo, Agatton, and Meiberg, situated on the banks of the Formosa, and inhabited chiefly by Dutch colonists, who carry on a considerable traffic.

The country of Benin is low and flat, much covered with wood, and intersected in many places with rivers and small lakes. In some parts of it, however, particularly on the road from Agatton to Formosa, there is no water to be found. Yet even there trees and plants grow to great perfection; and the whole country between Agatton and Formosa is adorned with orange and lemon trees. Cotton is the most abundant production of this country, and forms the principal article of

dress. Pepper, likewise, grows here, though neither in such quantities nor in such perfection as in India. Two sorts of wine are made use of in Benin, called wine of Pali, and wine of Bordon; the first of which is drunk in the morning or at noon, and the latter in the evening. Jasper-stones are almost the only mineral production of this country mentioned by travellers. Though one of the richest kingdoms in Guinea, Benin contains scarcely any gold-dust, which is found in almost every other part of the western coast of Africa. Its shores, however, abound in fish of almost every kind, and are particularly celebrated for a species of blue coral, which forms a lucrative branch of trade. The quadrupeds of this country are elephants, tygers, leopards, wild boars, civet cats, mountain cats, horses, hares, and sheep with fleeces of hair. Its principal birds are parroquets, pigeons, partridges, storks, and ostriches. Crocodiles, sea-horses, and a particular species of torpedo, swarm in the rivers.

The climate of Benin, though somewhat various, is in general unwholesome. The pleasantest, or rather the most tolerable, season is in the months of August and September; for then the air is refreshed by frequent rains. Tremendous thunders and lightnings prevail during the months of June and July. But the most noxious season is in the months of October, November, and December; when the heat is intolerable, and the country is perpetually enveloped in thick pestilential fogs.

One of the most prominent features in the character of the inhabitants of Benin, is their friendly and benevolent disposition. They are extremely courteous and hospitable to strangers; and are so anxious not to be outdone in generosity, that when an European gives any of them a present, they never fail to repay it two-fold. Nor are they less attentive to the comfort of their indigent countrymen. They have many institutions, which breathe the purest spirit of humanity. The king, the viceroys, and the grandees, give subsistence to the poor in the towns of their respective residence, by employing in various offices those whom their age and health enable to work, and maintaining gratuitously the aged and infirm. Thus not an individual in the kingdom of Benin is allowed to pine in want, and beggary is altogether unknown. Indolence is another characteristic disposition of the natives of Benin. Only those whom poverty compels to work will submit to any kind of manual labour. The rest devote upon their women and slaves, the toil of cultivating the ground, and the practice of the few arts with which they are acquainted. The ladies of Benin, therefore, not only prepare the cotton, and manufacture it into cloth, but are employed as blacksmiths, carpenters, and tanners. Their workmanship is extremely rude; but this is an impeachment rather upon their means, perhaps, and the state of society in which they live, than upon their ingenuity. Next to cotton cloth, the most common productions of their industry are mats, baskets, and spoons, and other instruments of ivory, which are brought to some perfection.

The inhabitants of Benin are divided into three classes. The first consists of the three great lords who attend the king, and through whom alone all requests and applications can be conveyed to the throne. The next class is composed of the viceroys, or governors of provinces, and the street kings, whose office somewhat resembles that of our mayors and aldermen. All of these owe

their advancement to the recommendation of the three great lords; and on their appointment are presented by the sovereign with a string of coral, which they wear constantly about their necks, as a badge of their authority. To counterfeit that chain of office is felony; and even to lose it is inevitable death. The third class includes all the rest of the inhabitants. All these classes are the slaves of the sovereign, whose mandates are received with the most servile awe. But no subject of the king of Benin can be sold into foreign servitude. Even those, who are condemned to slavery for their crimes, are never sold to Europeans, nor transported from their native land. The women alone, oppressed and degraded throughout the whole of Africa, do not enjoy the advantage of that merciful law, but may be sold and transported at the will of their parents and husbands. Male slaves may, indeed, be purchased on the coast of Benin; but they are all strangers who have been taken in war, or who have fallen by any other accident into the hands of the natives.

The religion of this country is the same which prevails in all the nations of Guinea, and will therefore be more properly described under the article of that name. (See GUINEA.) Polygamy is here allowed without restriction; and jealousy, its invariable consequence, is felt in all its violence. Unmarried persons of either sex may indulge the tender passion without censure; but adultery, when detected, is generally punished with death. Male children are accounted the property of the king; but the females are left to the disposal of the parents. Infants of both sexes are circumcised when a fortnight old, and their bodies are marked with incisions, intended to represent particular figures. So strongly are the inhabitants of Benin attached to their country, that they account it the severest of all misfortunes to be buried in a foreign land. Those, therefore, who happen to die at a distance from home, are preserved for years till their bodies can be conveyed to the spot that gave them birth. The term of mourning for a near relative is generally limited to fourteen or fifteen days, and on these occasions it is usual to shave the head or beard. The funeral obsequies of their kings are celebrated in a frantic and barbarous manner. The tombstone is covered with a banquet of the richest dainties, and the most delicate wines, of which all present are allowed to partake. The mourners, when heated with liquor, run about like madmen, killing all without distinction who come in their way, and having cut off their heads, they carry them to the royal sepulchre, and throw them along with the garments and spoils of those whom they have sacrificed, as an offering to the manes of their departed sovereign.

With the exception of the Portuguese, who have an insignificant factory at Awerri, the Dutch are the only Europeans who have any establishments in the kingdom of Benin. The king has allowed them to erect a magazine at Agatton, where they carry on a considerable trade. The articles which they export are pepper, ivory, the oil and bark of the palm tree, slaves, leopard skins, and acori, or blue coral. In exchange for these, they import red and scarlet cloths, drinking-cups with red stained brims, all sorts of fine cotton, woollen stuffs, linen-cloth, oranges, lemons, and other green fruits preserved, red velvet, ear-rings of red glass, copper bracelets, &c.

The natives are extremely faithful in their dealings, but so slow, that it is often eight or ten days before they

have made the necessary arrangements for a single article of commerce. Every native who engages in trade pays a certain sum to government by way of tax, but no duty is levied on the articles in which they trade. Europeans pay a custom so trifling as scarcely to deserve mention. (u)

BENIN, the capital of the above kingdom, is pleasantly situated at the mouth of the river Formosa, in the midst of a flat but beautiful country. Its streets, which are very long and broad, are constantly filled with the various articles of commerce, and present the bustle of a crowded market; yet they are always remarkably clean. The houses are large, and though their walls are of clay, the reeds and leaves with which their roofs are covered, give them a very pleasing appearance. This town is said to be about four miles in circumference. It stands at the distance of 69 miles from Agatton, in Lat. 6° 10' North, Long. 5° 6' East. See Smith's *Voyage to Guinea*; Peuchet's *Dict. de la Geog.* &c. (u)

BENISOUEF, is a large and opulent town of Egypt, about a mile and a half in circumference, situated on the west bank of the Nile. Though the houses are only small buildings coarsely constructed of brick, yet the beautiful and lofty minarets which it contains, have a magnificent appearance when seen from a distance through the tall date trees which shelter the town. The soil of the surrounding country is very productive; and in the town there is a manufacture of coarse carpets. Benisouef is the residence of a bey. According to the accurate observations of M. Jaccotin, Benisouef is situated in East Long. 31° 13' 0", and in North Lat. 29° 8' 28". See Savary's *Travels*; and Sonnini's *Travels*. (u)

BENLAWERS. See PERTHSHIRE.

BENLAWMOND. See DUMBARTONSHIRE.

BENTLEY, RICHARD, one of the most celebrated critics of whom England can boast, was born at Oulton, in Yorkshire, of obscure parents, on the 27th of January 1662. He received the first rudiments of classical learning at the free school of Wakefield, and in his fifteenth year was entered at St John's College, Cambridge. Here he pursued his studies with unparalleled assiduity and success. In the course of a few years he had filled a thick quarto volume with a kind of Hexapla, in the first column of which was every word of the Hebrew Bible, alphabetically arranged, and in the other five columns, all the various interpretations of those words to be found in the Chaldee, Syriac, Vulgate, Latin, and Septuagint, as well as in Aquila, Symmachus, and Theodosian. At the same time, he had compiled for his own private use another volume in quarto, containing all the various readings and emendations of the Hebrew text, collated from these ancient versions. In 1681 he left the university, and taught a school at Spalding. Soon after he was chosen as preceptor to the son of Dr Stillingfleet, dean of St Paul's, who appointed him likewise to be his domestic chaplain. The first work which he published, was a Latin epistle to Dr John Mill, containing critical observations on the chronicon of Malala, the Greek historiographer. This work appeared in 1691; and about the same time, he had the honour of being appointed as the first person to preach the lecture founded by Mr Boyle, for the vindication of the fundamental principles of natural and revealed religion. The sermons which he delivered in this capacity, were published at the desire of the respectable trustees to whom he owed his appointment, and contain the best confuta-

tion of the absurdities of atheism ever given to the world. Literary honours, accompanied with more substantial advantages, now began to crowd upon him. In December 1693, he was appointed keeper of the Royal Library at St James's; and such was his zeal and activity in this new situation, that before his patent was signed, he had enriched the library with about a thousand volumes, due to it in virtue of a neglected act of Parliament, which directs, that one copy of every book printed in England should be presented to St James's, and to each university. Soon after his nomination to this office, he became involved in a controversy, which, though trivial in itself, derived considerable importance from the character of the parties by whom it was carried on, and attracted for a long time the attention of the literary world. The honourable Charles Boyle applied to Dr Bentley, by means of a London bookseller, for a manuscript copy of the Epistle of Phalaris, which he intended to publish. It was obtained after much solicitation and many delays, and had not been above six days in the hands of Mr Boyle, when it was re-demanded by the Doctor, with some expressions of contempt both for the work and the editor. This insult was resented by Mr Boyle in his preface to Phalaris; Bentley in return, wrote a dissertation on the Epistles of Themistocles, Socrates, Euripides, Phalaris, and the fables of Æsop, maintaining, and indeed proving in the most satisfactory manner, that the epistles ascribed to Phalaris are spurious, and that Mr Boyle, by a very bad edition, had only rendered them more contemptible. Boyle retorted; a warm contest ensued; the literati ranged themselves under the standards of the different combatants; all the artillery of wit and learning was played off on both sides; till, as usually happens in such controversies, the immediate subject in dispute was relinquished for ill-natured sarcasm, and personal invective. Bentley was unfortunate in having all the contemporary wits, by whom he was dreaded, as his avowed enemies; but when the heat of irritation passed off, it was almost universally agreed, that he had the decided advantage over his antagonist in erudition and argument, and was but little inferior to him in refined raillery, and pointed wit. He was not so much occupied by this squabble, as not to find some leisure for his favourite employment of collating and commenting upon the classics. At the earnest request of his friend Grævius, he drew up animadversions and remarks on Callimachus, with a collection of some scattered pieces and fragments of that poet, which were published by Grævius on the continent in 1697. In 1700, he was made master of Trinity College, Cambridge, an office worth about 1000*l.* a year; and soon after was collated archdeacon of Ely. He was now placed in the situation of all others most suited to his habits and his wishes, and engaged, with new ardour, in the exercise of illustrating the classics. The two first comedies of Aristophanes, with his annotations, were published at Amsterdam in 1710; and about the same time, the fragments of Menander and Philemon appeared at Rheims, with his comments and emendations, under the feigned name of *Phileleutherus Lipsiensis*; a character which he again assumed in his attack upon Collin's Discourse on Freethinking. The most important of his critical performances, however, is his celebrated edition of Horace, which was published in 1711; and is pronounced by Dr Hare to be the completest work produced by criticism since the restoration of learning. In 1716, he

was appointed Regius Professor of Divinity in Cambridge; and in the same year, circulated proposals for a new edition of the Greek Testament, with St Jerome's Latin version. Few men could seem better qualified for such an undertaking. The greater part of his life had been spent in the critical study of the learned languages, with which he was most profoundly acquainted. His professional situation afforded him all the facilities which could be enjoyed in Britain; he had sent his nephew, Dr Thomas Bentley, in search of every manuscript which could be obtained on the continent; and was actually in possession of twenty different manuscripts, when his proposals appeared. They were received in the most flattering manner by all true lovers of learning; till Dr Conyers Middleton, always an inveterate enemy to Bentley, published remarks, paragraph by paragraph, upon his proposals, endeavouring to prove that he possessed neither the talents nor materials requisite for the undertaking. These animadversions chagrined Dr Bentley so much, that he determined the work should not appear during his lifetime; and the subscription money which he had received, amounting to about 2000*l.*, was immediately refunded to the subscribers. The last twenty years of his life were spent in a state of dignified ease. His only productions during all that time were, his editions of *Terence*, *Phadrus*, and *Milton*. His peace was considerably interrupted, however, at one period, by a quarrel in which he was engaged with the members of the college over which he presided. By reforming some abuses which had long existed, and curtailing salaries for which little was performed, he provoked those who thought themselves aggrieved, to enter a complaint, accompanied by a proposal for his removal, to the bishop of Ely, as visitor of the college. This gave rise to the question, whether the visitatorial power belonged to the bishop of Ely or the crown? After a long lawsuit, it was determined in favour of the crown; and though, in the present case, interference was declined, Dr Bentley was left in possession of his office. He again, however, excited a clamour against himself, for which there seems to have been more plausible grounds. Upon the creation, by royal mandate, of some doctors in divinity, he demanded from each a fee of four guineas, in addition to the customary perquisite. Here, as on every occasion, Dr Middleton was his most strenuous opponent? and although the graduates at first acquiesced in the demand, a decree was afterwards obtained for the repayment of the money; Bentley was arrested, and appeared by his proctor before the court of the vice-chancellor. It was declared by the beadle, on oath, that Dr Bentley had said, he would not be concluded by what the vice-chancellor and two or three of his friends should determine over a bottle; for which expression he was suspended by the vice-chancellor, without a hearing, from all his degrees; and afterwards, by a vote of the body, deprived of all his privileges, honours, and degrees in the university. In this perplexity he appealed to the king; and at length, after several references to the council and the court of king's bench, and many delays, a *mandamus* was sent to the university, reversing all their proceedings, and directing, that Dr Bentley should be restored to all the degrees, honours, and privileges of which he had been deprived. Of these he continued in quiet possession for twenty-four years after this decision; and died, on the 14th of July 1742, in the eighty-first year of his age.

He was buried in Trinity College chapel, by the side of the altar table, "where a square black stone records his name, and nothing more."

Detraction, we are told, is the tax which merit pays to envy; and never was that tax more heavily imposed than in the case of Dr Bentley. Superior in learning to all his cotemporaries, and scarcely inferior to any of them in acuteness and ingenuity, few could stand before him in the fair and open field of controversy. His antagonists, therefore, endeavoured to break the force of his attacks, by degrading his character,—decrying his erudition as scholastic lumber, and charging him with the arrogance of a bashaw, and the ferocity of a savage, because he despised their blunders and their ignorance, and unsparingly detected and censured their absurdities. Hence he has generally been regarded as a man of an irritable and overbearing temper; but if we may credit the testimony of one who had the best access to know him, the affections of his heart were no less gentle and amiable, than his talents were extraordinary and commanding. See Cumberland's *Memoires, ad initium; Biographia Britannica, &c.* (α)

BENYOWSKY, COUNT, the name of a Hungarian adventurer, who has been more praised than he deserves. The early part of his life was occupied in plots, conspiracies, and escapes, and in his better days, we find him in the service of France forming a settlement in Madagascar, and afterwards offering his aid, or rather his treachery, to several of the sovereigns of Europe. We are concerned to find that the life and history of such a man has been thought worthy of preservation. His abilities may have been brilliant, and his bravery undaunted; but he who was an outlaw from his native country, who could shine only in intrigues and conspiracies, and who could offer the power of his sword to the highest bidder, is a man whom posterity is under no obligations to remember. A soldier who fights for his native country, even in the worst cause, is a character which every person must revere. But the renegade, who wanders about in search of employment for his sword, and is willing to draw it against any foe, is a murderer by profession, who plunders without object, and slays without a provocation. Such a man was Benyowsky, and such a man it is impossible to admire.

Those who wish to know more of him, may consult "The *Memoirs and Travels of Count Benyowsky, written by himself*, 2 vols. 4to, 1790. (β)

BENZOIN. See **CHEMISTRY** and **MATERIA MEDICA**.

BERAR, a soubah or kingdom of Hindostan, which now forms the eastern division of the Mahratta empire. It is bounded on the north by Allahabad and Maliva, on the east by Orissa, on the south by Golconda, and on the west by Dowlatabad and Candish. Part of this province belongs to Nizam Ali, Soubah of the Decan. Wheat, rice, poppies, &c. are produced here in great abundance; and in the south of Berar are found the deer that yield the bezoar stone. Berar is divided into thirteen circars, and forty-two pergunnahs, and Nagpour is the capital. Its annual revenue, in the time of Aureng-zebe, was fifty-five krores of dams, or 1,718,750l. sterling. See Fraser's *History of Nadir Shah*, p. 26. (γ)

BERBERIS, a genus of plants of the class Hexandria, and order Monogynia. See **BOTANY**. (ω)

BERBICE, the name of a river of South America, in

the province of Guiana, which runs from south to north, and discharges itself into the Atlantic Ocean. It is chiefly remarkable for an extensive settlement formed upon its banks, in the beginning of the seventeenth century, by a Dutch colony.

The river itself is about a mile and a half broad at its mouth, where it is divided into two channels by an island, called Crab Island, about two miles in circumference. Owing to a bar of sand about five miles from its mouth, and stretching from east to west, the navigation is both difficult and dangerous. On this account, all vessels drawing more than four feet of water, are obliged to anchor at the port of Demerary, from which their cargo is carried to Berbice in colony schooners, that are again employed in conveying to Demerary the produce of the settlement. The colony of Berbice was founded in the year 1626, by Van Peer of Flushing, who sent out several ships to trade with the Indians. The colony had flourished to such a degree, that the French, who made a descent upon the coast, were able to extort a contribution of 20,000 florins. In 1678, the settlement was granted, as an hereditary fief, to the family of Van Peer. In consequence of another attack made upon the colony by a flotilla of French privateers, a contribution of 300,000 florins was paid for the safety of the settlement. This sum was discharged by the house of Van Hoorn and Company, who received in return three-fourths of the settlement. The new proprietors of this colony were permitted, by the Dutch East India Company, to import 240 negroes annually from Africa, at the rate of 165 florins a head; and the Company became bound to furnish them with a greater number, if it were necessary, at the rate of 250 florins each. They were also allowed to dispose of their lands and slaves, and to levy a duty of 300 florins from every vessel that came to the colony. By these means, the cultivation of sugar, cocoa, and indigo was greatly extended; many fruitless searches were made after mines; and settlers were invited to the infant colony.

The revenues of the colony arise from a capitation tax on the inhabitants; and excise on every fifty pounds of sugar that is made; a weighage toll of two per cent. on all exports and imports; and a duty of three florins per last on the tonnage of ships. The imported goods are the same as those carried to the other parts of the West Indies; and the exports are cotton, coffee, cocoa, tobacco, a dyeing stuff called rokou, but chiefly sugar, all of which are obtained from nearly an hundred plantations, formed on the banks of the river.

In consequence of the dampness and marshiness of the coast, the early settlers built a town and fortress, called Zealandica, fifty miles up the river. The increase of the colony, however, and the difficulty of navigating the river, induced the settlers to build the town of New Amsterdam on the south side of the river Canje, or Conya, where it discharges itself into the mouth of the Berbice. The houses extend up the banks of the latter river about a mile and a half. Each house, with a quarter of an acre of land annexed to it, is surrounded by a trench, which is filled and emptied at every tide. The houses are a story high, and are very long and narrow, with galleries on both sides to afford a shelter from the sun. They are generally thatched with troolie and plantain leaves for the sake of coolness, but the quantity of vermin which is harboured in this kind of thatch, has induced the English settlers to employ shingles. The government-house and the buildings annexed to it are

of brick, and are remarkable for their splendour and magnificence. The entrance of the river is guarded on the east side by fort St Andrew and a small battery, while the York redoubt defends it from the opposite bank. The colonial government propose to fortify Crab Island; but this is a matter of no importance, as Berbice must always fall along with the contiguous colony of Demarary. The west banks of the river were first cultivated; but, in 1799, the country, as far to the east of the river as the Devil's Creek, was rapidly cleared of its wood, and became an extensive cotton plantation. The lands on the banks of the river Canje have also been put into a state of cultivation, and produce sugar, coffee, and plantains. This river is navigable for colony schooners for about fifty miles from its embouchure, and is remarkable for immense falls and cataracts near its source. About 40 miles below its head, there is a creek connected with the river Courantine, by which overland dispatches have been brought from Surinam by the Indians.

In the year 1796, Berbice capitulated to the English, who reinstated in his office the former governor Van Batenburg. In 1799, when Surinam surrendered to the British arms, the governor of Berbice entered into a negotiation with Governor Frederici, by which Surinam ceded to Berbice the tract of land between the Courantine and the Devil's Creek, which was speedily put into a state of cultivation. At the peace of Amiens, Berbice, along with Demarary, was restored to the Dutch government. The troops which were sent to protect the colony suffered great distress from the want of proper food and accommodation, and all their applications for redress were disregarded. A mutiny was thus occasioned, which could not be quelled without the assistance of troops from Demerary and Surinam. After the mutineers had surrendered themselves to the government, Berbice surrendered to the British under General Grinfield and Sir Samuel Hood, in September 1803, since which time it has continued in our possession.

The population of Berbice amounts at present to 43,500; of whom 1000 are free people of colour, 2500 are whites, and the rest are negroes, the number of whom is doubled within the last ten years. The colony of Berbice was bounded on the east by the Devil's Creek till the year 1799, when its eastern limits were extended to the river Courantine. It is separated, on the west, from the colony of Demerary by Abarry creek. The breadth of the settlement, from the mouth of the river Courantine, is about 45 geographical miles; its former breadth being only about 30. New Amsterdam is about 52 miles to the south-east by east of Stabroek, the capital of Demerary. West Long. $57^{\circ} 20'$, North Lat. $6^{\circ} 20'$. (ii)

BERCHTOLSGADEN, **BERCHTESGADEN**, or **BERCHTOLSGADEN**, a town in the principality of the same name in the Austrian empire, containing a population of 3000. The inhabitants are chiefly employed in the manufacture of ivory, bone, and wooden toys, which they sell to the merchants of Nuremberg, and in the retail of salt to the surrounding country. The principality of Berchtolsgrad, along with that of Salzburg, form a separate province of the Austrian empire, which lies between the parallels of longitude $32^{\circ} 20' 15''$ and $35^{\circ} 50' 15''$ east, and between the parallels of latitude $46^{\circ} 55'$ and $47^{\circ} 50'$ north. It contains a superficies of 181 geographical square miles, and supports a population of

216,000, or 210,018 according to Hassel. The salt produced in Berchtolsgrad alone amounts, in one year, to 37,000 quintals. There are in this province six towns and twenty-five villages, of which Salzburg, Hallein, and Berchtolsgrad, are the chief. The statistical account of the province of Salzburg and Berchtolsgrad, comprehending an account of the salt mines with which it is enriched, will be given with more propriety under the article SALZBURG. See *Tableau Statistique de la Monarchie Autrichienne*, par M. Raymond et Roth, Paris, 1809; *Geographie et Statistique de toute la Monarchie Autrichienne*, par K. Hammerdoerfer, Leipz. 1793; and *Hist. et Mem. de la Société des Sciences Physiques de Lausanne*, 1787, 1788, tom. iii. (w)

BERDOA, an extensive province of Africa, comprehending the towns of Berdoa, Fobabo, Arna, and Burgou, and situated to the south of the desert of Barca. (j)

BERENICE'S HAIR, the name of one of the constellations in the northern hemisphere, containing in the Berlin catalogue 48 stars; in that of Flamstead 43; in that of Hevelius 21; and in that of Tycho 14. See *ASTRONOMY*, p. 750. (w)

BERESOF, or **BERESOW**, a district of Russia, in the province of Tobolsk, situated between the Ural Mountains and the Straits of Waygats. For an account of the gold mines of this district, see Tooke's *View of Russia*, vol. iii. p. 296.; and **URAL MOUNTAINS**. (j)

BERG, the name of a grand duchy, formerly in the circle of Westphalia, but now a separate principality attached to the confederation of the Rhine. It is a mountainous though fertile district, and is watered by the Wipper, the Sieg, and the Ruhr. The vallies produce corn in abundance, and excellent pasturage; while the mountains, covered with extensive forests, inclose valuable mines of lead, iron, and coal. The grand duchy of Berg, as it is constituted at present, (1811) contains a superficies of 201 square miles, and a population of 610,000. Its military force is 8000 men, and its annual revenue 2,300,000 florins. See *Aperçu de l'Etat actuel de l'Allemagne*, par M. Ockham, 1809. (o)

BERGAMO, the *Bergomum* of the ancients, is a city of Italy, formerly the capital of the district of Bergamasco, but now of the department of Serio, well fortified, and situated on several hills between the Brembo and the Serio. Bergamo contains thirteen parish churches, and twenty-two convents. It carries on a considerable commerce in woollen and silken stuffs; and its serges and tapestry have been held in high estimation. A communication below ground connects the city with the castle upon the hill. The cathedral is a large building. A well frequented fair is held here on St Bartholomew's day, and the building used on this occasion is the most remarkable thing in Bergamo. The gates of this town are regularly shut at a fixed hour, as if the country were the seat of war. The population is generally reckoned at 30,000; but Chantreaux makes it only 20,000. East Long. $9^{\circ} 45'$, and North Lat. $45^{\circ} 18'$. (j)

BERGEN, or **BERGHEN**, the largest town in Norway, and the capital of the province of Bergenhuys, is a seaport town built in the form of a crescent round a gulf of the sea, which forms one of the finest harbours in Europe, defended by seven lofty mountains, and by several fortifications; but particularly that of Fredericksburg. Though all the public buildings and several private houses be built of stone, yet the greater part of the buildings are of wood. The castle, the cathedral, school, and some parish churches, are its principal public edifices. The

imports of Bergen are chiefly corn and foreign goods, and its exports are hides, timber, fish, fish oil, and tallow. The merchants of the Hanseatic league attempted to monopolise the trade of Bergen, and to exclude even its own inhabitants; but in consequence of the vigorous opposition made by Walkendorf, this monopoly was destroyed, and the merchants expelled from the place. Bergen suffered dreadful losses by fire in the years 1428, 1623, 1640, 1702, 1756, and 1771, in the last of which, the reflected light of the conflagration is said to have been seen in the Shetland isles. Population in 1769, 13,735, and in 1799, 16,000, according to Catteau. In 1768, the exports of Bergen were 695,760 risdales and 75 schellings, and its imports 421,754 risdales and 64 schellings. In 1790, it exported 958,000 risdales worth of fish. In 1799, Bergen had 53 vessels above ten lasts. East Long. $5^{\circ} 33'$, North Lat. $60^{\circ} 23'$. See Busching's *Geog.* vol. i. p. 369; and Catteau's *Tableau des Etats Danois*, vol. ii. (q)

BERGEN, the capital of the isle of Rugen, belonging to Sweden, is situated on a rising ground nearly in the middle of the island. It contains only six stone buildings; the streets are sloping and bad, the lanes dirty, and the houses mean. The town, which is divided into four quarters, and inhabited chiefly by tradesmen and husbandmen, is governed by two burgomasters, two chamberlains, four councilmen, and a secretary, from whom there is an appeal to the court at Griefswald. There are here three fairs annually, at which a considerable quantity of linen and cattle is disposed of. The surrounding soil is high and sandy; but the low grounds are well adapted for the cultivation of corn. Number of houses 3000; population 15,740. (H)

BERGEN or **ZOOM**, a small but beautiful maritime town of Dutch Brabant. It stands on a rising ground in the middle of a morass, on the river Zoom, where it joins the Scheldt, and was defended by regular fortifications in the year 1629, under the direction of the celebrated Cohorn. The church, the market-place, and squares, are large and well built. The subterraneous gallery by which the French entered by surprise, in 1746, and the ravelines of Cohorn, where the breach was made, are still to be seen. East Long. $6^{\circ} 8'$, North Lat. $51^{\circ} 32'$. (j)

BERGERA, a genus of plants of the class Decandria, and order Monogynia. See **BOTANY**. (w)

BERGERAC, the largest though not the chief town of the department of Dordogne, in France, divided into two parts by the river Dordogne. In the arrondissement of this town, there are manufactures of paper, besides forges and foundries of cannon. Population 8540. East Long. $0^{\circ} 37'$, North Lat. $44^{\circ} 51'$. (j)

BERGIA, a genus of plants, of the class Decandria, and order Pentagynia. See **BOTANY**. (w)

BERGMAN, **TORBERN**, **SIR**, a celebrated Swedish chemist, was born at Catharineberg, in the province of West Gothland, on the 20th March 1735. His father, who was receiver of finances in the district, destined young Bergman for his successor in office; but the disposition which he began to display, seemed to be hostile to the intentions of his family. His friends, and the whole neighbourhood, were annoyed by his extreme petulance and forwardness. He seized all things that came in his way, and amused himself by throwing them into the fire, and observing the manner in which they were consumed. Neither threats nor punishment could overcome this scientific propensity; and to such a de-

gree was it carried, that when any thing was lost in the vicinity, young Bergman was accused of having burnt it.

Having finished the early part of his education at Skara, a place celebrated by its college, he was sent at the age of 17 to the university of Upsal, and was placed under the charge of a near relation. The ardour with which he cultivated the study of mathematics and natural philosophy, was checked by his guardian, and the *Elements of Euclid*, the *Astronomy of Keill*, and the *Principia of Newton*, were among the books prohibited by this enemy of the sciences. But the mind of Bergman could not be restrained by such unworthy fetters; and though he appeared to yield a becoming submission to the will of his relation, he contrived, by means of a drawer concealed under his table, to get possession of his favourite authors, when sleep or absence had disarmed the vigilance of his friend. Being thus compelled to study at those untimely hours, when nature would have prompted him to seek for repose, his body was unable to support the exertions of his mind, and he was obliged to return to Catharineberg to seek the restoration of his health in the bosom of his friends, and in the retirement and exercises of a country life. In consequence of the recovery of his strength, he returned to Upsal in 1754, with the permission of his family, to devote himself wholly to the sciences. The illustrious Linnæus, who then lived at Upsal, was in the zenith of his fame. Encouraged by his example, and aspiring to a portion of his glory, the youth at Upsal sought for distinction in the study of natural history. The ardent mind of Bergman was particularly actuated by this generous impulse. He began his career with the study of entomology; and such was the rapidity of his progress, that he soon attracted the particular notice of Linnæus himself. He made profound researches respecting several species of moths and caterpillars, and upon the tentredo or saw-flies, that are devoured by the larvæ of ichneumons, which feed upon their entrails, and cover themselves with their envelope. He divided the caterpillars into five species, depending on the disposition of their wings and feet. His observations on bees, and his useful experiments for the purpose of preventing the ravages committed upon fruit trees, by an insect called *phalena brumalis*, gained him the prize of the royal academy of Stockholm. The method of extirpation, suggested by these experiments, was tried by Mr President Cronstedt, who, in a short time, took above 20,000 of the females. His observations on leeches were equally interesting and successful. Linnæus and Muller had observed several species of these animals; but it was reserved for Bergman to observe their eyes and throat. He discovered that they were oviparous, and that the *coccus aquaticus* is the egg of the leech, containing 10 or 12 young. Linnæus, to whom Bergman communicated this discovery, at first denied the fact, but his incredulity was soon changed into conviction. He exclaimed, with enthusiasm, *vidi et obstupui!* (I saw and was astonished); and in signing the memoir upon that subject, he wrote these words at the bottom, and transmitted it to the academy of Stockholm, with that honourable passport.

The esteem which Linnæus felt for Bergman, in consequence of these discoveries, was at this time powerfully displayed, by giving his name to one of several new species of moths which he had detected. The other authors who shared this glory with the Swedish naturalist, were Forskal, Reaumur, Solander, Alstroemer, Frisch, Scroeber, Scopoli, and Geoffroy.

Though natural history was the general object of his studies, the attention of Bergman was occasionally directed to other subjects. In 1759, he published in the *Swedish Transactions*, a review of the different explanations of the rainbow. In 1760 appeared his paper on the origin of meteors, that are not attended with any noise or explosion; and another memoir on the opinion of philosophers respecting the twilight.

For several years, Bergman had given lessons in algebra in place of M. Melderereutz; and in the year 1761 he was appointed joint professor of mathematics and natural philosophy; a situation which he filled with honour and advantage for the space of five years. He observed the transit of Venus in 1761, with great accuracy. In consequence of a correspondence with Mr Wilson, Bergman wrote on the subject of electricity, in the years 1761 and 1762. He attempted to investigate the circumstances which attended the passage of the electric fluid across water; the effect produced by electricity on the colour of silk ribbands; and the electrical properties of tourmaline and Iceland crystal, which the Academy of Stockholm had referred to his examination. He published, in 1764, four memoirs on the aurora borealis, and attempted to determine the height in the atmosphere where this phenomenon takes place.

The studies of Bergman now received a new direction, in consequence of the resignation of Wallerius, a celebrated professor of chemistry and mineralogy at Upsal. Though chemistry had scarcely occupied his attention, Bergman had the boldness to appear in the list of competitors for this vacant chair. Wallerius, who supported the claims of one of his own pupils, formed against Bergman a powerful party, who represented him as unfit for the office to which he aspired. Bergman saw the strength of their representations, and the influence they might have upon his election; and resolved to oppose them by the most honourable weapons. He shut himself up in his laboratory, and composed a memoir on the preparation of alum, and on the most economical means of procuring it. This paper excited the astonishment both of his friends and his adversaries. The former regarded it as a triumph over the intrigues of his enemies, while the latter endeavoured to reduce and depreciate its merit. Wallerius himself condescended to attack it in the journals; but all these assaults tended only to ensure the success of its author. Gustavus, the Prince Royal, and afterwards the King of Sweden, who was then chancellor of the university, procured an accurate statement of the dissensions at Upsal, and applied to the famous Swab and Tiliaks, counsellors of the mines, for an account of the merits of the respective candidates. Having received the most favourable view of the character and talents of Bergman, the prince drew up, in his own handwriting, a reply to all the allegations urged against his favourite candidate, and presented it to the senate, who immediately appointed Bergman to the chemical chair.

It is singular to remark, to what accidental circumstances we frequently owe the developement of great talents. Natural history and the physical sciences, occupied the attention of Bergman till the 32d year of his age, and but for the resignation of Wallerius, or rather the generous interference of Gustavus, chemistry would have been deprived of those brilliant discoveries which immortalize his name. The duties of his new office imposed upon him the necessity of devoting his whole time to chemical pursuits; and he began his career

with all the ardour and fearlessness of enthusiasm. The public laboratory at Upsal was incomplete and ill arranged when it came into his hands. At his request the apartments were repaired and enlarged. The laboratory of Aurivillius was purchased. His own cabinet of minerals, along with those of Swab and Wallerius, were arranged in one apartment according to their chemical composition, and in another according to their geographical situation. In another apartment, he placed accurate models of all the articles of chemical apparatus, and of the various instruments used in the arts; and he completed his collection by the purchase of the best practical works on chemistry and the arts.

With these admirable auxiliaries, Bergman entered upon his ardent career. Exempted from the prejudices of theorists, and conducted by the torch of geometry, he began by repeating all the leading experiments in chemistry; he attended carefully to the various minute circumstances which seemed to affect the results; he marked the legitimate conclusions which his experiments authorised; and, by thus carrying into chemistry the principles of the philosophy of Bacon, he was rewarded by a variety of the most brilliant discoveries.

In examining the carbonic acid, or fixed air, which Dr Black had discovered in the composition of alkalis and calcareous earths, he found that it was a particular acid, and called it the aerial acid. By distilling sugar with nitrous acid, he obtained from it a very strong acid, differing from all others in its peculiar affinities, and which he also found to exist in honey, gum-arabic, in all the saccharine substances, and also in several animal products. He discovered likewise three new acids, viz. that of molybdena, that of tungstein, and that of phosphate of iron. The subject of earths next engaged his attention. He made numerous experiments on barytes; he shewed, that magnesia was not a calcareous substance, as had been generally supposed; and he proved, that silix differed from all other earths, and particularly from argil.

In the year 1773, Bergman published a memoir on crystalization, in which he shewed how the various forms of crystals could arise from a simple primitive form, and how this primitive form could be determined by the dissection of the crystal. This admirable theory, of which Bergman has laid the foundation, has been carried to great perfection by the Abbé Hauy, and the Count de Bourron.

On the analysis of mineral waters he published no fewer than six dissertations, which Macquer ranks among his most valuable productions. By employing new reagents, he gave a high degree of perfection to this kind of analysis. Instead of determining the quantities of the ingredients, by endeavouring to obtain them singly, he endeavoured to find the weight of one of the ingredients when combined with some well-known substance which he employed for this particular purpose. He examined also the composition of aerated and sulphureous waters; and he was the first who pointed out the method of forming artificial mineral waters.

His experiments on tartrate of potash and antimony, conducted him to the same results which had been obtained by Messrs Macquer and Lasonne; and in his analysis of volcanic products, of which numerous and valuable specimens had been brought to Sweden by Messrs Ferber and Troil, he exhibited a particular ingenuity, and detected the various operations of nature in the formation of these interesting substances.

In the analysis of many simple substances, and of several chemical compounds, he employed the blow-pipe with singular success. The composition of precious stones had hitherto been unknown, but, in the hands of Bergman, they submitted to an accurate analysis. With the simple apparatus of a blowpipe, a piece of charcoal, a small quantity of soda, and a little borax, he found that alumine, mixed with a portion of siliceous matter, of lime, and of iron, was the base of emeralds, sapphire, topaz, hyacinth, and ruby; that the proportional quantity of siliceous matter was successively increased in garnet, schorl, tourmaline, zircon, quartz, and rock crystal; and that gems were partly connected with siliceous stones, and partly with alum.

The researches of Bergman into the composition of metals and metallic oxides; his analysis of nickel and zinc; his explanation of the luminating property of several oxides of gold; his inquiries respecting crude iron, malleable iron, and steel, in which he shewed, that the various states in which iron appeared was owing to the admixture of phosphate of iron, manganese, and many foreign substances, chiefly metallic; his labours in the mines of West Gothland; his method of forming bricks of a durable nature; his investigations respecting the combination of mercury with muriatic acid; respecting the analysis of calculi and asbestos; and respecting sulphuretted antimonial preparations,—all these various labours can only be mentioned in this short sketch of his life.

The subject of elective attraction, which Geoffroy had begun in 1718, was resumed by Bergman with wonderful success. In order to complete this laborious undertaking, he calculated that no fewer than 30,000 experiments would be necessary; but finding that his health was unfit for such enormous labour, he arranged the materials which he had collected, and published very accurate and extensive tables of elective attractions. These tables were the first that contained the laws of affinities as they are observed in operating by the dry way. He has represented, by formulæ, all the chemical operations, the results of which form the basis of the table; and he has exhibited, at one view, the substances upon which he operated, the method employed, and the result of the operation. In his work on elective attraction, and in that on metallic precipitates, he has explained all the phenomena by the various modifications of the principle of phlogiston; but though the existence of this principle has been completely exploded by the discoveries of Lavoisier, these and his other works, will long continue to be resorted to by chemists, as the most valuable repositories of chemical facts.

Though the whole of Bergman's life was devoted chiefly to experimental chemistry, and to the discovery of facts, yet he did not scruple to venture into the regions of hypothesis. The combination of loose and unconnected facts by an hypothesis, however arbitrary may be its assumptions, is a great step to a legitimate theory; and, during the last century, has been of immense service to the progress of science. In former ages, when the method of induction was unknown, and when facts were accommodated to preconceived notions, hypothesis was fatal to the progress of discovery; but we have lately seen, what valuable accessions mineralogy has received from the contentions between the Huttonians and Wernerians. The theory of the earth which has been given by Bergman, supposes that the globe was originally a nucleus, probably magnetic, surrounded with a

fluid, which held in suspension or solution all the elements of bodies. In consequence of its rotatory motion, the equatorial parts swelled out from its centre: the denser and less soluble materials formed the first elevations upon the nucleus: the saline and metallic substances insinuated themselves into the crevices: the crystallizations were formed and deposited according to their affinities and densities: the waters, condensed towards the poles, became solid masses, constantly increasing; and being thus diminished in volume, they ran into the hollows among the mountains that gradually rose from below, and obeyed the force of universal gravitation: the lighter bodies floated on the surface, while others of greater density sunk to the bottom: gases of different kinds were disengaged from the earth, and meteors were generated in the atmosphere.

In 1773, Bergman published a Memoir on the principal characters of earths, which carried off the prize given by the Royal Society of Sciences at Montpellier; and some years afterwards his researches on the analysis of indigo were well received by the Academy of Sciences at Paris.

The short history which we have now given of the discoveries and writings of Bergman, includes the principal events of his life, which was marked by few incidents that can gratify the curiosity of his admirers. He was raised to the dignity of rector of the university of Upsal; and in this important office he maintained peace and tranquillity between the two parties into which the professors were divided.

In the year 1776, the king of Prussia invited Bergman to settle at Berlin among the illustrious characters, with whom that monarch had encircled his throne; but though a regard for his health might have incited him to remove to a warmer climate, yet the kindness which he had received from the king of Sweden prevailed over every personal consideration, and induced him to remain in his native country. The constitution of Bergman was now on the decline. Palpitations of the heart, and violent headaches, interrupted his labours; and his physicians advised him to abandon all his studies. He obtained great relief from natural and artificial mineral waters; and in the hopes of receiving more effectual benefit, he went to drink the waters at Medwi in 1784, but his strength was insufficient for the fatigues of the journey, and he expired soon after his arrival, on the 8th of July 1784, in the 50th year of his age.

In estimating the merits of this illustrious philosopher, we are not entitled to apply the standard by which talents are generally measured. When we consider only the extent of his labours, and the number and importance of his discoveries, we cannot fail to form the highest opinion of his industry and genius: but when we reflect, that all these labours were performed, and all these discoveries made, in the short space of 17 years, the talents of Bergman shine with new splendour, and we can scarcely find a place too high for him in the rank of chemical philosophers. Had Bergman entered upon the study of chemistry at an early age, and prosecuted it with vigour through the ordinary term of human life, what a vast accession of new facts would chemistry have received from his labours, and what a commanding station would he have held in the lists of genius.

During his short life, Bergman was created a knight of the royal order of Vasa; a member of the Academy of Sciences at Upsal; an associate of the Academy of Sciences at Paris; a fellow of the Royal Society of Lon-

don, and a member of the academies of Berlin, Stockholm, Dijon, Montpellier, Göttingen, Turin, Göttingen, and Lund; and after his death, the university of Upsal paid the highest honours to his memory, and a medal was struck by order of the Academy of Stockholm, to perpetuate the sorrow which they felt for his loss.

In the year 1771, Bergman married a Miss Catherine Trast, an accomplished and amiable lady, with whom he enjoyed all the happiness of domestic life but that which arises from a family. She was fond of botany and natural history, the studies which Bergman had unwillingly forsaken; and he derived great pleasure from seeing before him the plants and insects which she reared, and which had been the objects of his former researches.

The principal works of Bergman are, his *Opuscula Physica et Chemica, pleraque seorsim antea edita jam ab auctore collecta revisa et aucta*, 3 vols 8vo, 1779, 1780, 1783. This work was translated into English by Dr Cullen of Dublin, in 2 vols. 8vo, with notes and illustrations; and also into French by M. Morveau. *Physik Beskrifning af öfver Jordklotet*, or Physical Description of the earth, in 2 vols. *Essay on the utility of Chemistry*, which originally appeared in 1779 in Swedish, and was translated into English in 1783. *Meditationes de Systemate Fossilium naturalium*, published in the *Act. Upsal.* 1784, vol. iv. and translated into English in 1788. *De Primordiis Chemiæ*, 1777. *Chemiæ Progressus a medio*, Sæc. vii. ad med. Sæc. xvii. 1782. *Sciographia Mineralis*, Lips. 1782, translated into French by Mongez, and into English by Withering. See CHEMISTRY, and SCHEELE. (o)

BERGOO, a country of Africa, lying to the west of Abyssinia, and extending about 187 geographical miles from east to west, and 250 from north to south. Bergoo is governed by a sultan, who recruits his army from the inhabitants of eight large mountains, about a day's journey from Wara, the capital of Bergoo. The inhabitants of each of these mountains are said to speak a distinct language from the rest, and to be zealous Mahometans. This people, more humane than some of their neighbours, never make war for the express purpose of carrying off the prisoners or slaves. Though the Bergoos are Mahometans, yet many of their tribes which depend upon them are idolatrous and cruel. They devour the flesh of their prisoners, and preserve parts of their skin as tokens of bravery. See Browne's *Travels*, p. 310. (j)

BERKELEY, GEORGE, the celebrated and ingenious Bishop of Cloyne, in Ireland, was born at Kilkerrin near Thomastown, in the county of Kilkenny, being the eldest son of William Berkeley, Esq. a cadet of the noble family of earl Berkeley of Berkeley Castle. He received the first rudiments of his education at Kilkenny school, under Dr Hinton, whence Swift had, but a few years before, removed to the university; and was, at the age of fifteen, admitted a pensioner of Trinity College, Dublin, of which he became a fellow, June 9, 1707. He shewed a very early passion for literature; for before he was twenty, he had composed his ingenious mathematical essay, entitled, *Arithmetica absque Algebra aut Euclide demonstrata*, which he published in the same year that he was admitted a fellow of Trinity: and, in 1709, he published his justly celebrated *New Theory of Vision*, in which he establishes the very important conclusion, that magnitude as made known by the touch, is essentially different from magnitude as made known

by the eye, of which it is not the direct province to perceive the dimension of solidity, or to discern or judge of the distance of objects. A person born blind, he concludes, would, if suddenly restored to sight, be altogether unable to tell how any object that affected his sight would affect his touch; but would imagine, that all the objects he saw were in his eye, or rather in his mind.

The difference thus exhibited between the notions acquired by two of our senses, probably tended to convince Berkeley, that the objects of our perceptions are mere ideas, quite independent of material substance. In his *Theory of Vision*, however, he goes no farther than to assert, that the objects of sight are nothing but ideas in the mind; not denying, that there is a tangible world which is really external, and which exists whether we perceive it or not. But in his *Principles of Human Knowledge*, which he published in the subsequent year, he, without any ceremony, denies the existence of every kind of matter whatever; nor does he think this conclusion one that need, in any degree, stagger the incredulous. "Some truths there are," says he, "so near and obvious to the mind, that a man need only open his eyes to see them. Such I take this important one to be, that all the choir of heaven, and furniture of earth, —in a word, all those bodies which compose the mighty frame of the world, have not any subsistence without a mind." This deduction, however singular, was readily made from the theory of our perceptions laid down by Descartes and Mr Locke, and at that time generally received in the world. According to that theory, we perceive nothing but ideas which are present in the mind, and which have no dependence whatever upon external things; so that we have no evidence of the existence of any thing external to our own minds. Berkeley appears to have been altogether in earnest in maintaining his scepticism concerning the existence of matter; and the more so, as he conceived this system to be highly favourable to the doctrines of religion, since it removed matter from the world, which had always been the stronghold of the atheists.

Berkeley by no means confined his studies to metaphysics; for, in the year 1712, he published the substance of three sermons, delivered in the college chapel, in support of the doctrine of passive obedience; in consequence of which he was represented as a jacobite, and refused some preferment in the church of Ireland to which he had been recommended. This unfavourable impression, however, was removed by the good offices of Mr Molyneux, by whom Berkeley was introduced to the patronage of the Prince and Princess of Wales, afterwards George II. and queen Caroline. In the same year, he published, in London, a farther defence of his system of immaterialism, in *Three Dialogues between Hylas and Philonous*. He was at this period the friend of his two ingenious countrymen Swift and Sir Richard Steele; and was beloved and respected by both, though men of the most opposite principles. Through their good offices he became known to the most celebrated wits and learned men of the time; particularly Pope, Arbuthnot, and Addison, with whom he formed an intimacy that terminated only with his life. He was induced, by this intercourse, to become a contributor to the celebrated periodical works the *Spectator* and *Guardian*, which he adorned with several pieces highly favourable to virtue and religion.

It was through his friend Swift that he became known to the earl of Peterborough, who appointed him

his chaplain and private secretary, and whom he accompanied to Sicily and Italy in November 1713, in the capacity of ambassador. On returning to England in the ensuing year, he found that his hopes of preferment had expired with the change of administration; which induced him to accept the offer of travelling through Europe with the son of Dr Ashe, bishop of Clogher. At Paris he visited the celebrated Father Malebranche, who was then in a declining state of health, and engaged with him in so keen a metaphysical argument, that an increase of the disorder of Malebranche, which was an inflammation of the lungs, was the consequence. In fact, the learned father died a few days afterwards, viz. October 13, 1715. On his way home, he drew up, at Lyons, a curious tract, *De Motu*, which he transmitted to the Royal Academy of Sciences at Paris, and afterwards published in London in 1721. He was likewise the author of an *Essay towards Preventing the Ruin of Great Britain*, printed in the same year, and occasioned by the disastrous South Sea scheme of 1720.

Upon his return, his acquaintance among the great was considerably extended; and Lord Burlington, who had conceived for him a high esteem when at Rome, on account of his taste for architecture, obtained for him the grant of the deanery of Down, worth 2000*l.* per annum. Through the narrow system of politics, however, which then prevailed in the Irish cabinet, considerable opposition was made to his appointment; and such was Berkeley's mildness and humility, that he could not be prevailed upon to dispute the matter, or even expostulate on the subject. His noble patron afterwards, in 1724, procured for him the deanery of Derry, the next best in Ireland to that of Down, and worth 1100*l.* per annum. Upon this preferment he resigned his fellowship to which he had been appointed in 1717, in which year, also, he had received the degrees of bachelor and doctor in divinity. About this time he obtained an agreeable accession to his income by the death of Mrs Vanhomrigh, the Vanessa of Swift, who made Berkeley one of her executors, and left him half her fortune, amounting to about 4000*l.*, although she had been but once in company with him. In his capacity of executor, he committed to the flames several letters that had passed between her and the dean, not, as he expressly declared, because there was any thing criminal in them, but because there was a warmth in the lady's style which he thought it delicate to conceal from the public.

Previous to his appointment to the deanery of Derry, the benevolent mind of Berkeley had been busied in the noble plan of converting the savage Americans to Christianity, by erecting a college in the Bermudas or Summer islands, which might likewise be a seminary for more completely supplying the churches in our foreign plantations. In 1725, he published a proposal for this purpose in London; at the same time offering to resign his lucrative benefice, and to dedicate the remainder of his life to the instruction of youth in America, on the moderate income of 100*l.* per annum. Three junior fellows of Trinity College, Dublin, influenced by this distinguished example of disinterestedness, offered their services in the intended seminary on a salary of 40*l.* yearly, in room of all their prospects at home. After much solicitation and attendance on the great, Berkeley succeeded in having his favourite measure approved by government, and introduced into the House of Commons by Sir Robert Walpole. A char-

ter was granted by his majesty for erecting a college, by the name of St Paul's college, in Bermuda, which was to consist of a president and nine fellows, who were obliged to maintain and educate Indian children at the rate of 10*l.* a year for each.—20,000*l.* was allotted for this philanthropic purpose, of which one half was furnished by the ministers, and the other half was to be afterwards advanced. Berkeley and his associates were permitted to retain their livings in Ireland till this sum should actually be paid; but were bound to resign them in a limited time after the payment should take place. The benevolent dean lost no time in carrying this favourite plan into execution; but, in 1728, passed over to America, having a little before united himself in marriage to the eldest daughter of John Forster, Esq. speaker of the Irish House of Commons. Upon his arrival at Newport, in Rhode Island, he contracted for the purchase of lands on the adjoining continent, and fully expected that the purchase money would, according to agreement, be immediately paid. His expectations, however, were disappointed; and, after various delays and excuses, he was at length informed by Bishop Gibson, in whose diocese, as bishop of London, the whole of the West Indies was included, that upon application to Sir Robert Walpole, he received the following remarkable answer: "If you put this question to me as a minister," said Sir Robert, "I must and can assure you, that the money shall most undoubtedly be paid as soon as suits with public convenience; but if you ask me as a friend, whether Dean Berkeley should continue in America expecting the payment of 10,000*l.*, I advise him by all means to return home to Europe, and give up his present expectation." Accordingly the dean, after having expended a great part of his private fortune, and more than seven years of his life, in the prosecution of so laudable a scheme, found himself compelled to return to England. Before he left Rhode Island, he distributed the books he had brought with him among the clergy of that province; and, upon his arrival in London, immediately returned all the private subscriptions that had been advanced for the support of his undertaking.

In 1732 he published the *Minute Philosopher*, a performance which has been very generally read and admired. It consists of a series of dialogues, on the model of Plato, of which it is the object to refute the tenets of the free-thinker, who is here exhibited successively in the various characters of atheist, libertine, enthusiast, scorner, critic, metaphysician, fatalist, and sceptic. At this period he stood high in favour with queen Caroline, who was a distinguished patroness of men of virtue and talents. Upon a vacancy in the see of Cloyne, in 1733, at the instance of her majesty, Berkeley was appointed to that bishopric, and in May 1734 he was consecrated bishop of Cloyne, and vacated his deanery. On that occasion he said to his intimates, "I will never accept a translation;" a resolution to which he most religiously adhered; for when he was offered the see of Clogher in 1745 by Lord Chesterfield, then lord lieutenant of Ireland, he respectfully declined the promotion, although that see was double in value to the bishopric of Cloyne. In the discharge of his episcopal duties, he was in the highest degree meritorious and exemplary, and was distinguished by his pastoral hospitality, and constant residence. While his health permitted, he was a regular preacher; and always delivered extemporaneous sermons; for it is not known that he ever reduced a single

sermon to writing, with the exception of one preached before the society for propagating the gospel in foreign parts, which was published at their request.

About this time he published *The Analyst*, a very ingenious performance, intended to show that there are mysteries or unintelligible principles admitted by mathematicians in their reasonings, and particularly in the doctrine of Fluxions, which might be much more justly objected against than the mysteries of faith, which are often alleged as inadmissible by the enemies of religion. This work originated in the following circumstance: Mr Addison having visited Dr Garth in his last illness, addressed him seriously on the necessity of preparing for his approaching dissolution; to which the Doctor replied, "Surely, Addison, I have good reason not to believe those trifles, since my friend Halley, who has dealt so much in demonstration, has assured me, that the doctrines of Christianity are incomprehensible, and the religion itself an imposture." This conversation being reported by Addison to Berkeley, the bishop wrote *The Analyst*, as a confutation to this redoubtable dealer in demonstration. In 1735, he published *A Defence of Freethinking in Mathematics*, being a reply to Philaethes, supposed to be Dr Jurin, who had opposed the doctrines of the Analyst. In the same year also, he published a small pamphlet on this subject, entitled, *Reasons for not replying to Mr Walton's full Answer*, &c. For some time after this, his attention seems to have been directed to the public affairs of his country; and his *Queries*, for the good of Ireland, published in 1735; his *Discourse addressed to Magistrates*, in 1736; and his *Maxims concerning Patriotism*, in 1750, were a valuable fruit of this application of his mind. In 1745, during the Scottish rebellion, he addressed a letter to the Roman catholics of his diocese; and in 1749, another to the clergy of that persuasion in Ireland, under the title of *A Word to the Wise*, which was so well received by them, that they returned him their public thanks, with expressions of marked esteem and respect, which describe him as "the good man, the polite gentleman, and the true patriot." He has also acquired considerable celebrity as the author of "*Siris, a chain of philosophical reflections and enquiries concerning the virtues of Tar water*;" which was reprinted in 1747, and followed in 1752 by *Farther thoughts of Tar water*, the last of his publications. Berkeley thought that he received great benefit from this medicine, in allaying a nervous colic, to which he was subject during the decline of life.

In 1752, he adopted the resolution of removing with his wife and family to Oxford, in order to superintend the education of one of his sons. Entertaining a firm conviction of the obligation of residence upon every clergyman, he endeavoured to exchange his bishopric for some canonry or headship at Oxford; and not having succeeded in this, he requested permission, by a letter to the secretary of state, to resign his bishopric, worth at that time not less than 1400*l.* per annum. When the petition for this purpose was presented to his majesty, he declared that he should die a bishop, in spite of himself; and gave him full liberty to reside wherever he pleased. Before he left Cloyne, however, he directed the rents of his demesne lands, amounting to 200*l.* a year, to be distributed among the poor. At Oxford he was in the highest degree respected and beloved; but his residence there was destined to be very short. Whilst his lady was reading to him one of Sherlock's sermons

on the evening of Sunday, January 14th, 1753, he was suddenly seized with what is called a palsy of the heart, and instantly expired. His remains were interred at Christ Church, Oxford, where a marble monument was erected by his widow, with a Latin inscription by Dr Markham, afterwards archbishop of York. In this inscription he is said to have been born in 1769; but it is stated in the *Biographia Britannica*, on the authority of his brother, that he was born in 1684, and consequently died at the age of 69.

Berkeley was of a comely figure, a benign and impressive countenance, and of a robust constitution, till his health was impaired by his sedentary habits. Few persons were ever held in higher estimation by those who knew him than this excellent prelate, whose worth was of so high a standard as to render the praise of Pope scarcely hyperbolic, when he ascribes,

"To Berkeley every virtue under heaven."

Bishop Atterbury, after having been in company with Berkeley for the first time, on being asked his opinion of this excellent person, exclaimed with admiration, "So much understanding, so much knowledge, so much innocence, and such humility, I did not think had been the portion of any but angels, till I saw this gentleman." That the knowledge of Berkeley was greatly diversified, and extended to the arts and business of common life, as well as the depths of science, is amply testified by the author of the *Court of Augustus*, Dr Blackwell, whom the bishop wished to engage as one of the professors of his new college in the Bermudas. "I scarce remember," says Blackwell, "to have conversed with him on that art, liberal, or mechanic, of which he knew not more than the ordinary practitioners. With the widest views, he descended into a minute detail, and grudged neither pains nor expense for the means of information. He travelled through a part of Sicily on foot; clambered over the mountains, and crept into the caverns, to investigate its natural history, and discover the cause of its volcanoes: and I have known him sit for hours in forgeries and founderies, to inspect their successive operations. I enter not into his peculiarities either religious or personal: but admire the extensive genius of the man, and think it a loss to the western world, that his noble and exalted plan of an American university was not carried into execution. Many such spirits in our country would quickly make learning wear another face.

It is thought, that, towards the close of his life, Berkeley began to doubt the solidity of metaphysical speculations; and on that account turned his thoughts more to the subjects of politics and medicine. The ingenious romance, entitled the *Adventures of Signior Gaudenzio di Lucca*, has been repeatedly ascribed to his pen, but without sufficient authority. This performance, it is believed, was the production of a Romish priest, who wrote it for his amusement while a prisoner in the tower of London. A complete edition of the works of Berkeley, with an account of his life, and several letters, was published in two volumes quarto in 1784; and a volume, containing his smaller pieces, under the title of *Miscellanies*, was printed under his own inspection at Dublin in 1752. (m)*

* BERKELEY SPRINGS. These springs take their name from the county in Virginia in which they exist.

BERKHAMSTEAD, the *Durobriva* of the Romans, a market town of England, in Hertfordshire, situated on a branch of the river Dale, and the grand junction canal. It consists of one street, handsome and broad. It carries on a trade in bark, shovels, and spoons, which are made of beach wood. Number of houses 333. Population 1690, of whom 167 were returned as employed in trade. See Salmon's *Hist. of Hertfordshire*.

BERKSHIRE, one of the most beautiful of the inland counties of England, is bounded on the north by the Thames, which divides it from Oxfordshire on the westward, and Buckingham on the eastward; on the east by part of Surrey and by the Thames, which there separates it from Buckinghamshire; on the south by Surrey and Hampshire, and on the west by Wiltshire, and a small portion of Gloucestershire. It extends from 51° 19' to 51° 48' North Lat. and from 34½' to 1° 43' West Long. Its extreme length from Old Windsor to Buscot is about 48 miles; and its extreme breadth from Witham to Sandhurst (which, by the way, is taking rather an oblique line) is about 29 miles. Its circumference is nearly 208 miles. The boundaries which nature has assigned to Berkshire are in general highly picturesque. The Thames, meandering in a very varied line along its northern and eastern sides, throws it into such an irregular form, that, while in some places it is nearly thirty miles in breadth, in others it is less than four. On the south, the hills of Surrey and Hampshire afford a charming variety of landscape; and from the eminences in its western extremity, the eye is gratified with many enchanting scenes in the adjoining counties of Gloucester, Oxford, and Wiltshire. Dr Beeke, professor of Modern History in the University of Oxford, from astronomical observations which determined the longitude of that place, and from the trigonometrical survey taken by order of government, makes Berks, including some insulated parts, to contain about 464,500 square acres, according to the following distribution :

	Acres.
Arable land about	255,000
Meadows and dairy land in the Vale . . .	72,000
Sheep walks, chiefly uninclosed	25,000
Other dry pastures, parks, &c.	30,000
Wastes, chiefly barren heaths	30,000
Woods, copses, &c.	30,000
Other space occupied by buildings, } courts, fences, roads, rivers, &c. }	27,500
Total	469,500

They are situated in the town of Bath, and county of Berkeley, on the river Potomack, in a fertile country; and have within a few years been much frequented by invalids. The water is a little warmer than common water, and very soft. The waters prove diuretic, if, after taking them, the patient uses exercise. But if he remain quiet, they will purge gently and copiously. They have no particular taste: they have rendered much benefit to persons labouring under jaundice or affections of the liver. We know of no analysis of these waters; but, from their effect, we may suppose them to contain neutral saline matter, probably sulphate and muriate of soda. **CUTBUSH.**

From the report published by order of the House of Lords in 1805, it appears, that, "the area of Berkshire is 744 square statute miles, equal to 476,160 statute acres; the number of inhabitants on each square mile, containing 640 acres, is 147 persons, making a total of 109,368." This county is distributed into eight political divisions, viz. Faringdon, Wantage, Abingdon, Wallingford, Maidenhead, Oakingham, Newbury, and Reading. These again are subdivided into twenty-five hundreds; containing in all twelve market-towns, 148 parishes, 67 vicarages, and about 670 villages and hamlets. The names of the market-towns are Abingdon, Faringdon, Hungerford, Isley, Lambourn, Maidenhead, Newbury, Oakingham, Reading, Wallingford, Wantage, and Windsor. Abingdon, Reading, Wallingford, and Windsor, are parliamentary boroughs, but Abingdon returns only one member. Reading and Abingdon are both considered as county towns. With regard to its ecclesiastical connections, Berkshire lies within the province of Canterbury, and the diocese of Salisbury. It is subject to an archdeacon, whose jurisdiction extends no further than the limits of the county; it is divided likewise into four deaneries, Abingdon, Newbury, Wallingford, and Reading. The grand divisions of Berkshire marked out by nature are four. 1. The VALE, generally called the White Horse Vale, extending from Buscot to Streatly, and bounded on one side by the Thames, and on the other by the White Horse Hills, a continuation of the Chiltern range. 2. The CHALKY HILLS, which run nearly through the centre of the lower part of the county. 3. The VALE OF KENNET. 4. The FOREST DIVISION, commencing on the east of the Loddon, and extending the breadth of the county to Old Windsor. The principal rivers and streams in Berkshire are the Thames, the Kennet, the Loddon, the Lambourn, the Ock, the Aubourn, the Emme, and the Broadwater. Most topographical writers take notice of a peculiarity in the Lambourn, that its stream is always full in summer, and almost lost in winter. Mr Lyson, who denies this peculiarity, admits at the same time, that it preserves throughout the whole year a pretty equal degree of fulness, being seldom affected by the drought of summer, or subject to inundation in the winter. Berkshire has no stagnant waters of any consequence. In the tract of the Broadwater there is one particular spot, where it spreads in winter over a surface of about 100 acres; and this is called the Rascombe Lake; but in summer it is generally left dry.

The substratum of this county may be said to consist, in general, either of chalk and other calcareous matter, or of gravel, with clay at greater or less depths, according to the quality of the soil. The Vale is remarkably fertile, and its prevailing soil is a strong, grey, calcareous loam, in which vegetable mould is intimately mixed with cretaceous earth. Among the chalky hills, there are some intermediate tracks of considerable fertility, where the superficial stratum is composed of vegetable mould, mixed with chalk, flint, and gravel. In general these hills form excellent sheep-walks, being covered with a fine turf. In the Vale of Kennet, gravel soils predominate, varying, however, considerably in their qualities, admixtures, and depths from the surface. In this district there is a peculiar kind of peat, which is equally valuable as fuel or manure. The northern parts of the Forest district are distinguished by a soil of gravel, strong loam, and clay;

the central parts by a tenacious clay; and the southern parts by sand and gravel.

Berkshire can boast of no valuable minerals, nor of any variety of curious fossils. In the chalk-hills nothing remarkable has been discovered, except the substance from which they take their name. At Catsgrove, near Reading, there is a stratum of chalk, 30 feet in thickness, lying upon a bed of flint. Above the chalk is a stratum of sandy clay, about a foot thick, covered by a layer of oyster-shells, two feet in depth. Above these shells there is a stratum of sandy clay, one foot and a half thick; next succeeds a greenish sand, to the depth of four feet; over this three feet of a coarse fuller earth; and above all a very deep bed of clay, fit for tiles and bricks. Similar strata of sand, with oyster-shells, are found for two miles round Reading, at various depths, from 15 to 25 feet. Here likewise have been discovered an inferior kind of ochre, and different species of echini. Fossil shells, sharks teeth, parts of fishes, and other marine productions, are found in various parts of the county; and bones of animals and branches of birch trees have been dug out of the gravel pits and marshy moss-lands in Windsor forest. Pipe-clay and potters-clay are found in considerable quantities; and shell-marl was discovered in the vale of Kennet in 1794, though it does not appear to have been applied to any useful purpose. Sarsen stones are irregularly scattered over the downs of Berkshire. They are composed of a fine siliceous grit, and are frequently blasted with gunpowder, and used for pitching. But the most remarkable mineral substance in Berkshire is its peat, which is almost exclusively confined to the vale of Kennet. It is defined by Mr Kirwan as a "stratification of fossil trees in all directions, mixed with a reddish, or brownish-red slimy moss, formed of the carbonic particles of vegetables, and united with their astrigent juices, and calorific oleaginous fæculæ." Mr Davy, who analysed this peat, found it to consist of

Oxide of Iron	49
Gypsum	52
Muriate of sulphur and potash	20
	<hr/>
	100

At Cumner, near Oxford, there is a mineral spring, which possesses a mild cathartic quality. There is another of a mild chalybeate nature at Sunninghill, near Windsor; and Gorrick well, in the parish of Oakingham, is strongly impregnated with steel, and may be supposed to have some powerful tonic virtues.

The climate of Berkshire, though somewhat various, is in general pure and salubrious. In elevated and exposed situations, particularly in the central parts, along the course of the White Horse Hills, the air is keen and piercing; but in the more sheltered and champaign spots, the atmosphere is equally exhilarating, and salutary to the most delicate constitutions.

There are few counties in Britain where the landed property is so happily divided as in Berkshire for the purposes of general improvement. Though its annual rental, including houses, mills, and other productive revenue, arising from, or attached to the soil, cannot amount to less than 500,000*l.*, the largest estate in the county probably does not exceed 8000*l.* a-year; a few more may amount, in annual value, to 5000*l.*, 6000*l.*, or 7000*l.*; but great landed owners are rare,

either among peers or commoners. Property is least divided in the lower part of the county; yet even there the yeomanry is respectable, both in number and in circumstances; and in the upper part are to be seen several handsome seats, on estates not exceeding 100 acres. One of the happiest consequences of this wide and equal division of property, is, that the scale of rank ascends by almost imperceptible gradations, from the lowest to the highest; and all classes of the community are connected by close and indissoluble bonds. The yeomanry, depressed by no slavish dependence on superiors, nor overawed by the glare of disproportionate grandeur, feel within themselves all the native dignity of man, and cherish those lofty and generous sentiments of independence which should animate every free-born heart. This exalted character of the yeomanry has a reciprocal influence on the character of the nobility and men of fortune. Aware that no ascendancy can be obtained over the minds of their countrymen by the arts of corruption, they chuse the more honourable way of securing their favour by meriting their esteem. No where, indeed, are rank and property more impotent than in Berkshire. It was observed on a particular occasion by the late Mr Pitt, whose authority on this subject is unquestionable, that "no minister of this country could command ten votes in Berkshire." A higher testimony could not be given to the virtuous independence of its inhabitants.

From what we have said of the division of property, it may well be supposed, that the number of freeholders in this county is very considerable, and it is regularly increasing. Estates are frequently purchased on speculation, and sold out again in lots; and so general has been the violation of entails, that few estates are now occupied by the lineal descendants of those to whom they belonged two centuries ago. The present value of freehold estates cannot easily be ascertained with accuracy. Some estates may be sold at 26 years purchase, and others as high as 55; but the average value may be stated, perhaps pretty fairly, at 28 years purchase, nett rent. It is highly favourable to the agriculture of this county, that the superintendance of many of the estates is devolved upon agents; and that many gentlemen of considerable landed property are most zealous promoters, and skilful judges, of agricultural improvement. By far the greatest portion of the land in Berkshire is freehold, though, in different parts of the county, there are copyhold lands, held by different tenures, according to the customs of their respective manors. The lords of the manor are, in some places, disposed to enfranchise their tenants, on equitable terms; and the advantage of this practice, both to lord and tenant, will probably soon make it general. Leases on lives, and leases renewable every seven years, under deans and chapters, and other corporate bodies, are pretty frequent in Berkshire. But the benefit of these leases is almost wholly destroyed by the magnitude of the sum demanded at their renewal. A few estates are held by leases of 1000 years; and others are leased on one or three lives, by individual proprietors; but this practice is rare, and renewals are generally refused. The lands of Berkshire are parcelled out into farms of all sizes; a circumstance extremely conducive to the welfare of a country, as men of different capitals are thus induced to apply themselves to agriculture, and to emulate each other in their schemes of improvement, and in their efforts to obtain an independent, or a comfortable livelihood. The rent is generally paid in mo-

ney, except when lands are held under colleges and chapters; in these, the usual reservations of corn-rents, and sometimes of malt, are still retained. Stipulations are seldom made by the proprietors for any services, beyond what are connected with the repairs of buildings on the respective farms; and an allowance is generally made to the tenant of from three to six months rent in hand. There is nothing peculiar in the tythings of this county, except in the parish of Cumnor, where the parishioners who pay tythes have a claim to be entertained at the vicarage on the afternoon of Christmas, with four bushels of malt brewed into ale and beer, two bushels of wheat made into bread, and one-half hundred weight of cheese. Money is now given in lieu of this singular entertainment. The poor rates in 1803 amounted to 4s. 11d. in the pound, amounting in all to 96,860l. It must be observed, however, that they are seldom assessed on the real rent, but, in several instances, are raised according to an old valuation, founded on unknown data.

As the soil of Berkshire is peculiarly adapted to wheat, great quantities of that grain are reared in every part of the county. Next to wheat, barley is raised in the greatest abundance, and is chiefly sent to London, after being made into malt. There are many large dairy farms in some parts of the county, particularly in the White Horse Vale. The cattle are large and valuable, but there are here no native and peculiar breeds. Snows-wick, a farm in the parish of Buscot, is famous for cheeses in the shape of pine apples. They are peculiarly rich and delicate in flavour, and sell considerably higher than cheeses in the common form. About two tons of them are made in good years on this single farm, which indeed is the only place, as far as we have learned, where they are manufactured. Berkshire has a peculiar breed of sheep, the distinguishing qualities of which are their great size, their height on the legs, and weight when fatted: they have black faces, Roman noses, black or mottled legs, and long tails. They are particularly adapted to the low and cold lands; and when fatted, vary as much in weight as from 14 to 40 pounds a quarter. The native hogs of this country are inferior to none in the world for compactness, casiness in feeding, and the size to which they can be brought. They are usually crossed once in six or seven generations with the Chinese or Tonquin race, which prevents them from degenerating; and one gentleman has used a half wild boar to improve his breed with the greatest success. The number of turnpike roads in Berkshire affords the farmer every facility in carrying the produce of his industry to market; but though several of the roads are good, and follow the most judicious lines, they are frequently very inferior to what the abundance of valuable materials in every part of the county, and the ample revenues, would entitle the traveller to expect. Few inland counties possess such advantages in point of navigation as Berkshire. In its western division, no part of the triangle formed by the Thames on the north-east, the Kennet on the south, and the Wilts and Berks canal on the west, is distant more than twelve miles from water carriage; and in the east and south eastern parts, the distance is nowhere greater either from the Basingstoke canal, the Thames, or the Kennet. The Kennet and Avon canal, too, now executing under the powers of several successive acts of parliament, commences at Newbury; and that part of it within the limits of this county has been navigable ever since the year 1798.

Few manufactures are carried on in Berkshire. From the returns made to parliament in 1801, it appears that out of a population of 109,215, only 16,921 were engaged in trades, manufactures, or handicraft. Besides local manufactures for internal consumption, the only one of any importance is that of copper at the Temple mills. These mills are said to be the most powerful and complete in the kingdom. During war the copper is manufactured chiefly into bolts and sheathing for ships, in the service of government. In time of peace various kinds of sheets are formed for domestic purposes, and for foreign trade. The quantity of copper manufactured here is from 600 to 1000 tons. About fifty men and boys are employed in this establishment, which consists of a hammer-mill, a bolt-mill, and a flat rolling-mill, all worked by water.

We cannot dismiss this article without taking notice of the celebrated White Horse, which most antiquaries refer to Saxon origin, though Mr Lyson is of opinion that it is more likely to have been a work of the Britons, than, as is usually supposed, a memorial for Alfred's victory over the Danes. It is formed by paring off the turf from the brow of a steep chalky hill above Uffington, and from some points of view may be seen at the distance of twelve miles. It is now nearly obliterated by the grass growing on its surface. There are some other monuments of antiquity in Berkshire, but they are not of such importance as to merit particular notice in this place. See Mavor's *Agricultural Report of Berkshire*; and Lyson's *Magna Britannica*, vol. i. (μ)

BERLIN, a city in Germany, the capital of Brandenburg, and the residence of the Prussian court, is situated on the banks of the Spree, a considerable stream which falls into the Havel, one of the tributary rivers of the Elbe. The situation of Berlin is by no means agreeable, for it stands on an unvaried and sandy plain, but it combines almost every advantage of appearance and utility, which art, seconded by the beneficent policy of an enlightened monarch, has been able to confer. Frederic II., who employed all his intervals of peace in improving the internal condition of his states, bestowed much care and expense on the embellishment of his capital. Before the war of 1756, he had already reared several public edifices, and entirely rebuilt the suburb called Neuvoigtland, the houses of which he gave gratuitously to the proprietors. In that dreadful period of convulsion which ensued, Berlin fell twice into the hands of the enemy. Haddik, the Austrian general, entered that city in the year 1757, and in the space of 24 hours, carried off 200,000 German crowns. Three years after, it was seized by the combined army of the Austrians and Russians, who exacted from it two millions of crowns, a sum which it was necessary to borrow. The debt was liquidated by Frederic after the conclusion of the war, nobody knows at what period, nor was any additional burden ever imposed on the inhabitants for that reimbursement. Scarcely was peace restored, when he resumed, with new eagerness, his schemes of improvement. In eight years, (from 1769 to 1777,) he caused to be rebuilt 149 private houses, which he presented as free gifts to the proprietors; and during the last six years of his reign, (from 1780 to 1785 inclusive,) he expended 4,561,200 livres on the embellishment of this favourite city. Besides all this, he often gave wood and other materials to those who wished to build; and any person who engaged in that speculation, upon applying to government or the police, and conforming his plan to their general design.

received gratuitously from the quarry of Rudersdorf the quantity of limestone necessary for the foundations, and for mortar. The liberal schemes of Frederic were eagerly adopted by his successor Frederic William II.; who, besides erecting many houses which he gave gratuitously to private individuals, constructed the gate of Brandenburg, in the style of the Propyleum of Athens; part of the walls of the city; a stone bridge, and one of iron. The reigning monarch, too, after the example of his predecessors, has expended considerable sums in the embellishment of Berlin.

Berlin is about 11 miles in circumference. It is about $4\frac{1}{2}$ miles long, from the Muhlenthor on the south-east, to the Oranienburgerthor on the north-west; and its breadth is about three miles from the Bernauerthor on the north-east, to the Potsdamerthor on the south-west. The town has 15 gates, 268 streets, 36 bridges, 6922 houses, besides 33 churches, and numerous public buildings. The streets are in general pretty regular, and of a convenient breadth. Those in the south-west part of the town, called the new town, cross one another at right angles. Several of these streets are a mile long, and Frederick-street is fully $2\frac{1}{2}$ miles in length. The houses, which do not exceed two stories, are generally built either of fine white free-stone, or of brick covered with a thin coating of plaster.

There are several magnificent and interesting buildings in this metropolis. The royal palace is a splendid edifice. It was begun in 1699 by Frederic I., and though built at different periods, is chiefly from the designs of Schluter. Its length is 450 Rhinland feet; its width 276 feet; and its height, 101 feet. It is four stories high. The apartments, are remarkably spacious, and adorned with valuable paintings, rich tapestry, and numerous articles of furniture made of solid silver. There are likewise here several ancient statues, and a Roman chair decorated with bas-reliefs. The plain and simple apartment of Frederic the Great contains only four portraits, representing his particular friends. In the bowling-green before the palace, is a fine statue of the prince Dessau, executed by Professor Schadow. The library contains 100,000 volumes. Among these books are 500 Bibles, the most remarkable of which are, the Bible used by Charles I. when he was beheaded; the first Bible printed in German in 1450, and the first Bible printed in America. There is also here a singular copy of the Koran, written in such a small character, and on such a thin paper, that it is only $1\frac{1}{2}$ inches in bulk. This library is composed of five different libraries, which have been successively combined in one, and is under the direction of the Academy of Sciences.

The arsenal is one of the noblest buildings of the kind in Europe. Each of its fronts is 280 feet long. Above the great gate is a bronze bust of Frederic I. Level with the ground, is a statue of the same monarch by Schluter, which is much admired; and above the windows in the interior court, are 21 faces by Schluter, representing the various expressions of persons in the agonies of death.

The royal stables are magnificent buildings, with two courts, and between them a covered menage. In the rooms above the stables, are all the accoutrements, adorned with brilliants, of the horse on which Frederic I. made his public entry into Berlin; and in the armoury chamber are many ancient pictures and curiosities, among which is a drum covered with the skin of Ziska, chief of the Hussites.

The churches of Berlin are adorned with statues of the heathen gods; and Frederic III. before his death, began to fill them with the pictures of his warriors and statesmen. In the church of the garrison are four pictures by Rode, which represent the death of the four great Prussian warriors, Schwerin, Kleist, Keith, and Winterfeld; and likewise many standards and other trophies of Prussian valour. The church of St Nicholas is a building of great antiquity, and is remarkable for several fine pictures and sepulchres, particularly the monument of Puffendorf. Out of the 33 churches in Berlin, the Lutherans have 12. There are eight churches common to the Lutherans and the reformed church. The French reformed church has six churches. The Roman catholics have two churches. The Moravian brethren have one place of worship, and some other sectaries have another place for divine service. The Jews have also a synagogue here, and there are two churches belonging to the hotel of the invalids. In 1786, the Lutherans amounted to about 12,500, the catholics to 8000, and in 1798 there were 3421 Jews.

Besides these buildings, we may notice the opera house; the palace and gardens of Montbijou; the house and garden of Belvidere; the hall of the Academy of Sciences, which contains the anatomical theatre and the observatory; the magnificent hospital of invalids, which maintains about a thousand officers and soldiers; the palaces of Prince Henry and the Prince Royal; and the new Calvinist church of Old Coln, which contains the burying place of the royal family.

There are several large squares in Berlin, the principal of which is William's square, which is adorned with marble statues of the four great officers who distinguished themselves in the seven years war, viz. Schwerin, Seidlitz, Keith, and Winterfeld. Schwerin is holding out the colours which he seized from one of his officers at the battle of Prague, when his troops were giving way, exclaiming, "Let all, but cowards, follow me!" On the bridge over the Spree, there is a colossal and equestrian bronze statue of the Grand Elector Frederic William, which is reckoned the *chef d'oeuvre* of Schluter. The man and horse were cast in one piece, and the whole weighs 3000 quintals.

There are several excellent public walks and gardens in Berlin and its environs. Before the houses of Berlin, on each side, is a causeway, and between these causeways is a fine gravel walk, planted with lime-trees, which is always a fashionable place of resort. The park on the south side of the Spree is above three miles round, and is frequented by great crowds on Sunday, when they are provided with every kind of refreshment and amusement. The park at Charlottenberg, where the court resides in summer, is also an agreeable place of resort. At Bellevue is to be seen the bust of Prince Henry of Prussia, a *chef d'oeuvre* of Houdon, and also the monument of Baron Bielefeld. The environs of Berlin are remarkably pleasant, and are adorned with beautiful villas, canals, and vineyards. The palace of Schoenhhausen; the mineral waters at Fredericksbrunnen; the beautiful villages of Buchholz and Pankow; the view of the famous fortress of Spandau, from the top of the hill at Pickelswerder, are among the objects which adorn the environs of Berlin.

In Berlin there are numerous establishments for the advancement of literature and science, and for the promotion of useful and benevolent purposes. Besides the Academy of Sciences, which we have already fully de-

scribed in the article ACADEMY, there are ; the royal college of medicine and surgery ; the clinical institution ; the royal veterinary school ; the royal academy of arts and the mechanical sciences ; the royal academy of architecture ; the royal riding academy ; the royal military academy ; the society of physicians ; the pharmaceutical society ; the pedagogical society ; the academy of singing ; the philomathic society ; the humane society ; besides 5 colleges, an institution for the deaf and dumb, numerous schools with pensions, and 41 *hospices* for charity and health.

There are a great number of valuable manufactures carried on in Berlin. In the manufacture of silk no fewer than 2788 looms, and 5085 workmen were employed in the year 1799, and the value of what they manufactured amounted to 1,869,880 crowns. In the manufacture of woollen, cotton, and linen goods, 4224 looms were employed, and 4689 workmen ; the annual value of their work in 1799 being 2,850,760 crowns. In the various other manufactures, which are 44 in number, the workmen employed were 4337, and the annual value of their produce 3,522,480 crowns. The whole number of looms employed in Berlin were 7014, the number of manufacturers and artisans 14,406, the annual value of their work in 1799, 8,350,028 crowns, the value of the original materials 5,190,084 crowns, the value of the articles sold in the kingdom 6,844,922, and the value of those sold out of it 1,123,058.

Berlin is divided into five separate towns or wards, viz. Berlin Proper, Cologne or Coeln, Frederickswerder, Dorothestadt or Neustadt, and Frederickstadt. Berlin Proper, which was founded in the 12th century by a colony from the Netherlands under Albert the Bear, lies in an island formed by two arms of the river Spree. Cologne, which is probably of the same antiquity, also lies in an island formed by two arms of the Spree, and is separated from Berlin Proper by the principal arm of that river, which is crossed by four bridges, three of which are of stone and one of wood. Frederickswerder and Dorothestadt were both built by the Elector Frederick William, the latter of which he called after his wife Dorothy, and which is the finest part of Berlin. Frederickstadt was founded by the Elector Frederick III. forming the south-west part of the town, and joining with Frederickswerder. The streets are remarkably spacious and regular, and are adorned with lime-trees.

The interior œconomy of the houses in Berlin is far from corresponding with their outward appearance. In handsome houses, the apartments are in a ruinous state, and the furniture mean and dirty. Soldiers lodge in the ground floor, and mechanics of the lowest class occupy the upper story. A similar contrast exists between the external appearance of the inhabitants and the comforts which they enjoy at home. Every expence conducive to true comfort is grudged ; while nothing is spared to deck the persons of the ladies. The number of courtezans is greater in Berlin than in any other town in Europe of the same size, and they observe none of that external decorum which is to be seen among this licentious class in other parts of the continent.

During the 15 years from 1769 to 1782, M. Beguelin found the average temperature of Berlin to be 49°.

In 1645 there were only 1236 houses in this city ; in 1747, they amounted to 5513 ; in 1779, to 6437 ; and in

1790, to 6950. The population, including the garrison, of 30,000, amounts to 169,000, which is above 20 inhabitants to one house. East Long. 13° 26' 15", and North Lat. 52° 32' 30". BERMUDAS, or SOMERS' ISLANDS, are situated in the Atlantic ocean, in W. Long. 63° 28', N. Lat. 32° 35', and are between 200 and 300 leagues distant from the American continent, and the other West India islands. They were discovered in 1527 by John Bermudas, a Spaniard, who merely saw them at a distance, and gave them his name ; but who did not land upon them, or acquire any information concerning them. About the same time, Henry May, an Englishman, was shipwrecked upon one of the largest of these islands ; returned to Europe in a vessel of cedar wood, which he had found means to build there, by the help of materials collected from the wreck of his own ship ; and was the first who published any account of the Bermudas. They were found, at their first discovery, to be entirely uninhabited ; and though, in 1572, the king of Spain made a grant of them to one of his subjects, no settlement was formed upon any of them by the Spaniards. In 1609, Sir George Somers, Sir Thomas Gates, and Captain Newport, on their way to Virginia as deputy governors, were cast upon the Bermudas :* and disagreeing among themselves, each of them built a ship of the cedar growing upon the islands, in which they severally arrived at Virginia. Sir George Somers having returned to these islands in quest of provisions for the colony in Virginia, died there soon after his arrival ; and from him they have been called by the name of Somers' or Summer islands. His companions and crew, instead of returning as they had been commanded, with hogs to Virginia, sailed in their cedar ship to England ; and made so favourable a report of the beauty and fertility of the Bermudas, that the Virginia Company, who claimed the property, sold them to 120 purchasers, and James I. granted them a charter. In 1612, this Bermudas association fitted out a vessel, with sixty planters on board, under the government of a Mr Richard Moore. In the mean time, three English seamen, who had deserted from Sir George Somers, and remained in St George's island, had collected a considerable quantity of ambergris, which they found on the coast ; and were preparing to convey their valuable cargo in an open boat to Virginia, or Newfoundland ; when governor Moore arrived from England, seized and sold the ambergris as the property of the Company. This great, though scarcely just acquisition of wealth, gave new spirit to the adventurers ; and, under the good conduct of Moore, the island was soon fortified with eight or nine block-houses, the town of St George planned as it now stands, and considerable returns made to the proprietors in England in drugs, ambergris, cedar, tobacco, and other commodities. The infant settlement was alarmed by the threatening of an attack from some Spanish vessels, which appeared off St George's, when there was not above one barrel of gunpowder in the whole island ; but they fortunately re-

* From this event, Shakspeare is supposed to have taken the name and several of the incidents of his comedy. "The Tempest" Douce's *Illustrations of Shakspeare*, vol. i. p. 5

tired upon the first fire from the forts of the English. About the same time the Bermudas were greatly infested with rats, which had been imported in the European ships. They multiplied with astonishing rapidity; made dreadful havock for several years among their fruits and grain; and at length suddenly disappeared. In 1616, Moore was succeeded by Captain Daniel Tucker, who followed out the beneficial plans of his predecessor, kept the planters under the strictest discipline, and greatly encouraged the culture of tobacco. In 1619 he was succeeded by Captain Butler, who brought with him 500 new settlers; raised a monument to the memory of Sir George Somers; and established a new constitution of government, resembling, as nearly as possible, that of the mother country. There were now above 3000 English residing in the Bermudas; many of the first nobility had purchased plantations; and it became fashionable in England to visit these islands from motives of curiosity and amusement. From exaggerated accounts of the advantages of the climate, many persons removed thither from the Leeward islands for the restoration of their health; and others, from the northern colonies, to enjoy their fortunes in a peaceful retirement. Numbers of royalists took refuge in the Bermudas, during the usurpation of Cromwell; and, in 1643, the poet Waller, after his condemnation by the Parliament, spent several months in these islands, which he has described in his poems, as enjoying a perpetual spring, and as furnishing the most delightful residence in creation. Deceived by such flattering accounts of the serenity of the climate, and the manners of the inhabitants, the benevolent and ingenious bishop Berkeley made a generous, but unsuccessful attempt in 1725, to establish a college in the Bermudas, for the joint purpose of propagating Christianity among the American Indians, and of facilitating the education of the British youth in that country. See BERKELEY.

These islands, during the last half-century, have increased very little either in value, or in population. The navigation in their neighbourhood is dangerous; their situation is not favourable for trade; and they have been found very deficient in many of those advantages, which they were at first supposed to possess. It has been alleged even, that, in many respects, they have suffered a gradual deterioration; and particularly, that from the cutting down of the large cedar forests, which once covered the islands, sheltering them from the violence of the north winds, and protecting the growth of the more delicate plants, their climate has actually become less temperate, and their soil less productive.

The Bermudas are about 400 in number; but their whole compass does not exceed above six or seven leagues. Most of them are merely islets and rocks; and very few of them are habitable. The four principal islands are Bermuda, which resembles a hook in its form, 35 geographical miles in length, and about two in breadth; St George's, which has a capital of the same name, and which contains about 3000 inhabitants; St David's, which is contiguous to the former, and which supplies the town of St George with provisions; and lastly, Sommerset. The population of all the islands is not much above 10,000; and nearly one half of the inhabitants are blacks. The people in the Bermudas have been often celebrated for the correctness of their morals, their gentle treatment of their slaves, and their many useful and benevolent institutions. The women are said to be handsome; and both sexes are represented as

fond of dress. They are clothed chiefly with British manufactures; and most of their implements also are made in this country. The government is conducted by a governor, council, and assembly. The prevailing form of religion is that of the church of England; but there is one presbyterian place of worship.

The chief productions of the Bermudas are a soft white stone, which is easily cut, and which is exported to the West Indies for building; maize, vegetables, and most of the West India fruits in sufficient abundance for the support of the inhabitants; a great variety of tame and wild fowl; excellent turtle, which forms a very profitable branch of trade; palmetto leaves, which are manufactured into women's hats; tobacco, which is rather, however, of an inferior quality; and ambergris, once very abundant, but now procured in smaller quantities. A considerable number of the inhabitants are employed in the manufacture of sails; but their chief resource and occupation is the construction of small ships of cedar wood, which they sell to the Americans to good advantage, and which are much valued, in those seas especially, for the purpose of privateering. Part of their trade consists, also, in carrying salt from Turk's island to America; and they engage a little in the whale fishery. Several plans have been proposed for improving these islands; and their soil is considered as well suited for the culture of vines, silk, and cochineal. In 1785, the growth of cotton was attempted, but with little success; and in 1800, there were not more than 200 acres applied to that purpose. See Pinkerton's *Geography*, vol. ii. p. 631. Edward's *Hist. of the West Indies*, vol. i. p. 516. Raynal's *Hist. of West Indies*, vol. v. p. 52. *Modern Univ. Hist.* vol. xli. p. 339. (9)

BERN, the largest and most important of the thirteen cantons of Swisserland, is bounded on the north by the cantons of Soleure and Basle, and the Austrian forest towns; on the east by the cantons of Uri, Unterwalden, Lucern, and the county of Baden; on the south by the Valais, the lake of Geneva, and the duchy of Savoy; and on the west by the canton of Soleure, the county of Bienne, and part of France. Its extent embraces about one-third of Swisserland, and contains one-fourth of the whole population; yet it held only the second rank among the cantons, following immediately after Zurich. This canton is divided into two large branches or districts, called the German district, and the Roman district, or the Pays de Vaud; the former of which extends from Murat or Murten, to the Rhine; the latter from Murat to Geneva.

The rugged and stupendous mountains which encircle the canton of Bern, its deep and gloomy forests, its lakes and marshes, while they exhibit the most picturesque and varied scenery, seem at first view to promise but little fertility, and to present insuperable obstacles to the operations of agriculture. In common years, indeed, its crops are insufficient for the consumption of the inhabitants; yet there is no country in Swisserland which presents in general a more smiling appearance, and where the triumphs of labour are more strikingly displayed. Its marshes are converted into luxuriant meadows; the sides of its mountains are covered with vineyards; and rich harvests are extorted from every portion of the soil where it is possible to guide the plough, or to carry the spade. Previous to its subjugation by the French, Bern was one of the happiest countries in the world. With the exception of

the nobility, who disdained to engage in any business but the government of the state, every hand was employed in industry; a general air of prosperity prevailed throughout the land; and the hut, even of the lowest peasant, was the abode of comfort and content.

To give our readers an idea of the general appearance of this once-favoured country, we shall conduct him through its different provinces in an excursion from the capital, directing his view, as we pass, to the objects most attractive in its scenery, or most important as characterising the progress of improvement, the resources of the state, or the manners of the people. The small district immediately surrounding the capital, though by no means naturally fertile, is extremely interesting from the activity of its numerous population, animated by the facilities which the town affords for disposing of the fruits of their labour, to the most eager diligence in cultivating their fields. By far the most beautiful part of this district, is the valley between Bern and Thun. It is refreshed and enlivened by the river Aar, on the banks of which are many handsome villages; and the lowest parts of the mountains which bound the valley are adorned with castles and villas, equally delightful by the views which they command, the richness of their domain, and the number of their living springs. The rest of the province is occupied by mountains; on the heights, and the reverse of which, are seen forests of fir trees, mingled with beeches and oaks.

To the south of this district is Oberland, or the province of the Alps, which branches out into several valleys from the lake of Thun to the Glaciers. Nothing in the scenery of Swisserland is finer than the situation of the castle and town of Thun. They stand near the brink of a charming basin, which is formed by a lake surrounded by mountains in the form of an amphitheatre, above which appear in distant perspective, the aerial summits of the Alps, clad in everlasting snows. The banks of the lake are covered with vineyards, which, though not remarkable for their luxuriance or their quality, add much to the beauty of the scenery. Above these the country is rugged and high, sprinkled with some trees, and enlivened in summer by the herds and flocks that browse on its herbage. The valley which lies between the lake of Thun and the lake of Brientz, narrowed on each side by approximating mountains, has been aptly termed the *vestibule* of the Alps: It is formed entirely of stones rolled down by torrents from the mountains, and seems to have been interposed in some dreadful convulsion, as a barrier to the once united lakes which it now separates.

From the extremity of the lake of Brientz, the valley stretches for nine or ten leagues, regularly ascending till it meets the foot of the Grimsel, which forms a branch of the lofty ridge of St Gothard. This track, called the country of Hassle, is frequently inundated by the Aar, which, taking its source under the Glaciers, forms, before its fall into the lakes, a most impetuous and destructive torrent. The whole of this cold and sequestered vale is cheerless and ill-peopled; and as their herds form the only resource of its inhabitants, they seldom rise above poverty and want. The small valley between the two lakes presents a very different scene. Its temperate climate induces all the shepherds of the neighbouring Alps to assemble here in winter with their families; and in the extent of about two square leagues, it contains two towns, each the resi-

dence of a bailiff, and is covered with villages, cottages, and orchards. From thence we pass through the mouth of very savage mountains, into two insulated vallies. That of Lauterbrunnen on the right, terminating at the foot of the enormous glaciers of the Virgin, is remarkable for the cascade of the rivulet of Staubach, which, swelled by the rain, falls from a perpendicular height of eleven hundred feet. On the left, the very elevated valley of Grindelwald presents, amidst the horrors of a desert, the interesting picture of an Alpine colony, inhabiting a fertile and well cultivated spot of ground, terminated on the south by abysses of eternal ice. It was from these singular countries that the immortal poet of the Alps took the originals of his pictures.

To the south and south-east of the lake of Thun, extend the bailliages of Frontinguen and Siebenthal. The first forms a very wide and fertile valley in the lower part, which becomes narrower and wilder as the land is more elevated. At the southern extremity, a road is cut out of the rock which overhangs the precipices, conducting to the baths of Leuk, famous for the copiousness and medicinal virtue of its hot springs.

The frontiers of Oberland, on the south, present a chain of glaciers and snow-clad summits. Here, an elevated valley, extending between two of the loftiest ridges of the Alps, to the length of ten or twelve leagues, is filled by one unbroken mass of ice. Another chain of Alps, likewise intersected by glaciers, forms, on the north of the valley of Hassle, the frontiers of the cantons of Uri and Underwalden.

The province of Emmethal extends from Thun along the frontiers of Underwalden and Lucern. It is pervaded by broken chains of mountains and hills, which lower gradually towards the Aargau. The most elevated summits of these mountains are covered with wood, or with excellent summer pasturage; the sides which are well exposed to the sun are cultivated to a very great height, while the valleys present the picture of a rich and exquisite culture. No where do the peasantry enjoy more easy circumstances, and more real advantages, than in Emmethal. Besides the abundant productions of its soil, this province is enriched by its manufactures of cloth and ribbands; and affords a striking and instructive proof of the advantages resulting from the union of the arts of industry with agriculture, the first and most essential of all.

Between the Emmethal and the canton of Soleure lies the upper Aargau, an open country, abounding in rich meadows and fertile fields. The bailliage of Aarbourg separates the Upper from the Lower Aargau. Here the territory of Bern is contracted by the cantons of Lucern and Soleure to the breadth of half a league. To such perfection is the system of irrigation here carried, that the best meadows are valued at upwards of 5000 French livres an acre. The four counties of Aarberg, Erlach, Nidau, and Baren, form a district which extends from the lower extremity of Neufchatel Lake to the canton of Soleure. The soil of this district is in general fertile and well cultivated. This country reaches to the foot of Mount Jura, and borders on the bishopric of Basle.

The Pays de Vaud, chiefly wrested by conquest from the Dukes of Savoy, is the most extensive province in the canton of Bern, and is one of the most delightful and abundant countries in Swisserland. In the vicinity of the lake of Murat, the climate is mild, and the soil luxuriant. Vines, tobacco, and maize, are cultivated

there with the greatest success; orchards, stocked with every species of fruit trees, are bowed down to the ground by the weight of their fruit; and the meadows are covered with the richest and most beautiful pastures. The bailliages of Moudon, Oron, and part of Lausanne, stretch into Little Jura, separated from the Great Jura by the Gros de Vaud. This district is mountainous, and less productive than the Pays de Vaud; yet, except in the more elevated parts, it produces considerable quantities of grain.

In going from Moudon to Lausanne, it is necessary to cross a mountain; on descending the opposite side of which, the Lake of Geneva opens full on the view. This magnificent reservoir of water forms, on its northern bank, a curve of about fifteen leagues. The greater part of this district resembles the province of Oberland; but its lower region, washed by the Rhone from the confines of Valais, enjoys a warmer climate than any other part of the whole canton. At Beviex, (See BEVIEUX,) in this government, are the only salt springs to be met with in the country of Switzerland.

Proceeding along the border of the lake, we come next to Vevey, a handsome and flourishing town, surrounded by vineyards, behind which the country ascends, and is adorned with fields of corn, and covered with verdant pastures. Between Vevey and Lausanne are the four parishes of the Pays de la Vaud, the wines of which are in great request. The country above Lausanne, which is the second town in the canton, is mountainous, bleak, and uninteresting; but below the town, and opposite to the bailliage of Morges, the scenery is enchanting. Vineyards, meadows, and corn fields, indicate a genial soil; while these native beauties, aiding the picturesque illusion which different points of view produce on these charming banks, present the appearance of one vast continued garden. On approaching Morges, the climate still improves. That beautiful town stands at the bottom of a small gulf, where the lake of Geneva expands to its greatest breadth. The interior of this district is in general fruitful in grain, and extensive vineyards of the finest quality enrich and beautify the coast. The bailliages of Nyon, of Romainmotier, and Yverdon, complete the topography of this canton; but, as they are marked by no very peculiar feature, they scarcely deserve to be separately described.

If the different provinces of Bern vary in appearance, in soil, and in climate, there is an equally perceptible difference in the genius, the manners, and disposition of the inhabitants. The mountaineers of Oberland, the peasants in the environs of the capital, or in the province of Emmethal, the inhabitants of Aargau, and those of the four counties, are so many distinct nations, easily recognised by their language, their dress, and their manners. But the most striking difference takes place between the inhabitants of the German district, and those of the Pays de Vaud. The former are grave, cool, and contemplative; fond of their country, with which they are at the same time proud of being connected; dull in their pleasures, slow in their operations, but regular and systematic in all their conduct. No acquisition of wealth could ever excite in the breast of a peasant of this country the smallest ambition to connect himself with a noble family, nor would he even allow his children to intermarry with the citizens. He courts no office of power; he never voluntarily leaves his country; and when necessity has forced him from it, different habits and modes of life generally excite such a regret for his native land, as

becomes, especially among the mountaineers, a malady often fatal. The women of this nation are industrious, punctual in all affairs of household economy, assiduous in the cultivation of their gardens, in spinning, and in the other proper occupations of their sex.

The people of the Pays de Vaud are in general gay, and more polished; possessed of a livelier imagination, pliant in their character, working with more ardour than constancy, giddy, improvident, and fond of emigration. The women who have not been improved by visiting other countries, are unskilful in their economy, generally idle, gossiping, and negligent in the little cares of education and household management which belong to their province. A farm in the former country wears an air of order and comfort; in the latter it exhibits every mark of disorder and neglect.

Commerce has never been much cultivated in Bern. Its principal articles of exportation are horses, cattle and hides, cheese, linen, and cotton cloths, coarse cloth and canvas made of hemp, and woolen stuffs. Ten thousand pieces of linen are said to be annually sent out of this country, chiefly to Lyons. In the capital are established manufactures of silk, and coloured stockings. Clock-making and the polishing of false stones are the principal arts followed in the west of the mountains. For the history and former government of this canton, see SWITZERLAND. See *Dictionnaire de la Suisse*. Peuchet's *Dictionnaire de la Géographie Commercante*. Coxe's *Switzerland*, vol. ii. Moore's *View of Society in France, Switzerland, &c.* vol. i. (k)

BERN, a town of Switzerland, and the capital of the canton of the same name, is situated on the banks of the river Aar, which almost encircles the town. The principal streets of this city are long, broad, and gently curved. The houses are nearly uniform, and of the same height, and are built upon arcades, which afford, even in the worst weather, a dry and sheltered pavement for foot passengers. The streets are kept remarkably clean, by means of criminals, who remove the rubbish, &c. under the inspection of a guard; and the branch of the Aar which traverses the town, supplies several fountains, which contribute to the ornament of the town, as well as to the comfort of the inhabitants. The cathedral of Bern is a beautiful Gothic building, the cloister of which is particularly admired. It was erected in 1421 by the same architect who built the Munster at Strasbourg, and stands upon a fine terrace raised above the bed of the Aar, and commanding a charming view of the adjacent country. The arsenal formerly contained 60,000 stands, and several trophies of Swiss valour. The statue of William was one of the curiosities which it displayed. The public library comprehends about 20,000 volumes, besides a curious collection of antiquities and medals. It contains also a chart in relief of a part of Switzerland, a view in relief of the salt mines and glaciers of Beviex and Aigle, executed in wood by M. Exchaquet; a collection of curiosities from Otahete; a cabinet of Swiss medals, and a cabinet of minerals. Besides these public buildings, there are several hospitals, an almshouse, a house of correction built at the suggestion of Howard, and an elegant building for public amusements.

The principal literary and scientific establishments of Bern are, the Economical Society, the Society of Physics and Natural History, and the Society of Medicine, &c.

In the neighbourhood of Bern there are many delight-

ial views of the Alps, which appear in their greatest beauty when seen at the rising or the setting of the sun. These views are seen to great advantage from the terrace of the cathedral, the little rampart, the granary, Graben, and Engli. Between the lower gate of the town and the village of Ostermanningen, there is a charming promenade, diversified with the finest scenery.

There are few manufactures carried on at Bern. The principal are draps, linens, cottons, silks, and delft ware.

Bern is elevated about 1709 feet above the level of the sea. Population in 1792, 15,000. E. Long. $7^{\circ} 20'$, N. Lat. $46^{\circ} 56' 56''$. See Coxe's *Travels*, vol. ii. Moore's *View of Society in France, Switzerland, &c*; and *Dict. de la Suisse*. (π)

BERN MACHINE, the name of a machine for tearing up trees by the roots, invented by Mr Peter Sommer, a native of Bern. There is nothing either in the object or in the construction of this machine which entitles it to a description in this place. Any contrivances for tearing up trees, that exhibit ingenuity and originality of construction, will be found under the word TREES. See Dr Thomas Young's *Natural Philosophy*, vol. ii. p. 199. (ω)

BERNARD MOUNT. See ALPS.

BERNAY, a town of France, in the department of the Eure, containing a population of 6142. (ω)

BERNBURG, a town of Germany, and formerly the capital of the principality of Anhalt Bernburg. The principality of Bernburg now belongs to the confederation of the Rhine, and contains seventeen square geographical miles, and 38,000 inhabitants. Its military force is 600 men, and its annual revenue 600,000 florins. (π)

BERNERAY, a small island of the Hebrides, lying on the north side of North Uist, and separated from it by a channel about one and a half miles broad. This island, which has a fresh water lake, called Lochbruis, in its centre, is about four miles long and one and a half broad. This lake contains swarms of eels, which are often caught by the inhabitants twined together in heaps.

The tides at this island present some singular phenomena. About four days before and after the moon is in quadrature with the sun, between nine o'clock in the morning and nine at night, the tide runs eastward for twelve hours successively: At nine o'clock at night the current changes its direction, and runs westward till nine o'clock next morning. This phenomenon is daily repeated till the moon is within four days of her syzgy, when the tides resume their regular course, flowing to the west during the six hours of ebb, and to the east during the six hours of flood.

Between the vernal and autumnal equinox, the tides at the quadratures flow eastward during the day, and westward during the night, while from the autumnal to the vernal equinox, they move to the west during the day, and to the east during the night. Population of Berneray and Rathy, 494 in 1792. West Long. $7^{\circ} 8'$, North Lat. $57^{\circ} 42'$. See Macleod's account of the parish of North Uist, in the *Statistical Account of Scotland*. (j)

BERNIER'S ISLAND, a small island near the mouth of Shark's bay, on the west coast of New Holland, which received its name from the officers in the French expedition of discovery in 1801. This island is partly precipitous towards the east, and partly surrounded by

mighty breakers on extensive reefs, against which the waves dash with great violence from a wide expanse to the west. The substance of the island consists of horizontal beds of sand and limestone, containing many shells, all as regularly shaped as if formed of hewn mason work. Most of the shells encrusted in them are univalves, and chiefly belong to the genus *naticæ* of Lamarck: and they bear much resemblance to those of the same kind still found alive at the foot of the rocks in the sea. From their intimate adhesion to the masses involving them, and from being found at 150 feet above the present level of the sea, naturalists conclude that they have existed in a state of petrification during ages. Strata of a sort of calcareous breccia, susceptible of a sufficient polish, and of pleasing coloured shades, are seen in other parts of the island. The whole surface of the island is covered with a bed of quartzose sand, mixed with calcareous remains also, which having been originally light and moveable by the winds, forms a circle of sand-hills all around the shores between sixty and eighty feet high. But to prevent the disorders that would ensue from the perpetual change of these heaps, nature, amidst the low and languishing vegetation of the island, here produces a species of *cyperus*, whose long roots, universally interlarded throughout the ground, form an immense reticulation, which restrains them in their position, and binds the loose soil together. A farinaceous grain, somewhat resembling wheat, crowns the summit of this plant, in ears as large as the fist: but owing to the aridity of the soil, perhaps, it had not come to maturity, and each of the ears scarcely afforded two or three seeds. The French conceived that it might be profitably naturalised in the sandy districts of France and Spain, and there prevent the light soils from shifting with the wind. A singular *spinifex* growing in the most arid places, and composed of an innumerable quantity of leaves, extremely slender, in great mossy tufts, and a *mimosa* rising two or three feet from the ground, but spreading fifteen or twenty around, form the more remarkable of the few plants growing in the island. A beautiful quadruped, the *fasciated* kangaroo, inhabits this island in numbers, though it is not to be seen on the continent, nor on any other islands excepting two in the neighbourhood. It is excessively timorous; the slightest noise alarms it, and sometimes a breath of wind will put it to flight. Yet this little animal, though timid in self-defence, boldly resists the injury which is offered to its young. The females, like others of their genus, are provided with an external pouch, whither the young retire on the approach of danger: when wounded and feeble with the loss of blood, she could carry it no longer in flight, the mother assisted her offspring to get out of the bag that it might attempt its own escape: or, when forcibly separated, on regaining a place of safety, she would call to it by a peculiar sound, and after affectionately caressing it, as if to dissipate its alarm, cause it to enter its wonted place of shelter. Even when these animals get a mortal wound, their care was diverted from exertions for their own safety, and directed solely to the preservation of their young. Several young kangaroos were taken on Bernier's Island, but only one of the whole survived: it became very tame, and fed readily on bread, besides which it greatly relished sugar and water. Owing to an accident, it perished in the course of the voyage to which we have alluded; nevertheless, the species might possibly be naturalized in Europe. In this island neither birds nor reptiles are numerous, be-

ing principally cormorants, sea-eagles, and three lizards, one of which is between four and five feet long. The seas, which wash the shores of the island, abound with mollusca, and fishes, from whales down to microscopic polypi: and testacea, together with zoophytes, are found on the rocks, or deep in the waters. There is an edible oyster of very uncommon figure and delicious taste, solidly adhering to the former, and beautiful univalves are dragged up from the mud wherein they lie concealed. The *mytilus effulgens*, the finest hitherto discovered, is among them, of a shining colour, and reflecting all the prismatic colours. (c)

BERNOULLI, JAMES, a celebrated mathematician, was the fifth son of Nicholas Bernoulli, member of the grand council and of the chamber of finances of Basle in Switzerland, and was born at Basle on the 27th December 1654. James Bernoulli, the grandfather of the subject of this article, came originally from Antwerp, and established himself at Basle in 1622. He left behind him three children, the eldest of whom was Nicholas, who was born in 1623, and died in 1708; leaving a family of eleven children, among whom were James and John, two of the most illustrious mathematicians of the 18th century.

James Bernoulli was originally intended for the church, and, after having taken his degrees in the university of Basle, he entered upon the study of divinity. His attachment to mathematics, however, gradually withdrew his attention from the study of theology. His favourite pursuit engrossed the whole of his time; and without the aid of a master, and even without the assistance of books, which his father carefully concealed, he made such rapid advances in the science of geometry,* that before he was 18 years old, he resolved the problem of finding the Julian period, when the year of the solar cycle, the golden number, and the indiction, are given.

He began his travels in the year 1676; and when he passed through Geneva, he found out a method, different from that proposed by Cardan, of teaching a blind person to write, which he tried with great success upon a young girl, who had been blind from the age of two months. At Bourdeaux he computed universal tables for dialling, but they have never been given to the world. The attention of astronomers was at this time occupied with the famous comet of 1680; and such was the enthusiasm with which Bernoulli was inspired, that, on his return to Basle, he published a treatise on the subject, entitled, *Neu erfundene Auleitung wie man den lauff der Cometen, &c.* Bas. 4to, 1681. In this first production Bernoulli adopted the vortical system of Descartes, and maintained, that comets were the satellites of a large and invisible planet, which revolved round the sun in 4 years and 157 days, at the distance of 2583 semidiameters of the *orbis magnus*. Upon these principles, he predicted that the comet of 1680 would return on the 17th May 1719, and would be situated in the 12th degree of Libra; but, alas! his prediction, founded on such a theory, could not be otherwise than false, though, like Phaeton, to follow out the simile contained in his own device,

Magnis, tamen, excidit ausis.

Soon after the publication of this work he left Basle, and visited Flanders and Holland on his way to England,

where he was introduced to the most eminent philosophers of the times, and attended all their philosophical meetings in London. On his return to Basle in 1682, he commenced a course of public experiments on natural philosophy; and, in the same year, he published, at Amsterdam, his *Conamen novi systematis cometarum, pro motu eorum sub calculum revocando et apparitionibus predicendis*, 8vo, Amstel. 1682; a work not altogether unworthy of his genius. In 1682, he published his dissertation *De Gravitate Ætheris*, which is not distinguished by any peculiar marks of its author. It treats principally of ether, that hypothetical substance by which Euler, his great successor in the career of geometrical discovery, endeavoured to explain the various phenomena of nature. After this work was composed, Bernoulli found, that many of the views which it contained had already been given by Malebranche, in his *Recherche de la Verité*; and he declares in his preface, that he had not read that celebrated work.

About this time he established at Basle a kind of experimental academy, where he made a number of experiments on different points in physics. The professorship of mathematics at Heidelberg having become vacant in 1684, James Bernoulli was elected to that office, and, during the three years which he spent in that university, he devoted himself, with the utmost ardour, to the study of geometry. The paper of Leibnitz, entitled, *Nova Methodus pro maximis et minimis, itemque tangentibus, quæ nec fractas, nec irrationales quantitates moratur, et singulare pro illis calculis genus*, with the application of the calculus to the solution of several physical and geometrical problems, appeared in the Leipzig acts for 1684, and were the first attempts of that great philosopher to employ the new calculus which he had invented. The attention of James Bernoulli was particularly attracted by this paper, and he and his brother John, who had been studying mathematics under him, were so delighted with these elements of the differential calculus, that they embraced it with avidity, and by extending its limits, and applying it with success to several curious problems, they, in the opinion of Leibnitz himself, made the discovery in a great measure their own.

Before James Bernoulli entered upon this brilliant career of discovery, he was elected, in 1687, to the professorship of mathematics at Basle, an office which he filled with distinguished reputation during the whole of his life. He succeeded Peter Megerlin, who is known to astronomers as a zealous defender of the Copernican system.

In 1690 James Bernoulli solved the problem of the isochronous curve, of which Huygens and Leibnitz had already obtained a solution; and on this occasion he proposed the celebrated problem of the catenarian curve, which Galileo had tried in vain. Huygens, Leibnitz, and John Bernoulli soon obtained a solution; but this solution was extended by James Bernoulli to cases, in which the weight of the chain varies in different parts of its length, according to a given law. This able mathematician determined also the curvature of a bended bow, and that of an elastic rod, fixed at one end, and loaded at the other with a given weight. He found likewise, that the form of a sail, swollen by the action of the wind, is the common catenarian curve when the wind does not

* In reference to this restraint upon his inclination, he took for his device Phaeton driving the chariot of the sun, with the motto of *Injeto patre sidera verso*. "Against my father's will I traverse the heavens."

escape; but that it is one of the curves called *Lintearie*, when the sail is supposed perfectly flexible, and expanded with a fluid pressing in every direction. John Bernoulli published a solution of the same problem in the *Journal des Sçavans* for 1692; but it appears unquestionable, that he had received hints from his brother, who communicated to him, by letter, his opinion upon that subject.

The theory of curves, produced by the revolution of one curve upon another, now occupied the attention of James; and in this rich and untrodden field he made many interesting discoveries. He found, that the logarithmic spiral was its own evolute, antievolute, caustic, and pericaustic; and that the cycloid had a property analagous to it. The discovery of this constant reproduction of the logarithmic spiral was a source of such pleasure to Bernoulli, that, in imitation of Archimedes, he requested that a logarithmic spiral should be engraven on his tomb, with the motto of *Eadem mutata resurgo*, a beautiful and happy allusion to the future hopes of the Christian. Besides these discoveries, James Bernoulli solved the problem of the paracentric isochronal curve, proposed by Leibnitz in 1689, and also the problem of the curve of quickest descent, which his brother John had proposed in 1697.

About this time began that famous dispute upon isoperimetrical problems, between James and John Bernoulli, in which their talents were displayed to greater advantage than their dispositions. "These illustrious characters," as the writer of this article has elsewhere observed, "connected by the strongest ties of affinity, were, at the commencement of their distinguished career, united by the warmest affection. John was initiated by his elder brother into the mathematical sciences; and a generous emulation, softened by friendship in the one, and gratitude in the other, continued for some years to direct their studies, and accelerate their progress. There are few men, however, who can support, at the same time, the character of a rival and a friend. The success of the one party is apt to awaken the envy of the other; and success itself is often the parent of presumption. A foundation is thus laid for future dissensions; and it is a melancholy fact in the history of learning, that the most ardent friendships have been sacrificed on the altar of literary ambition. Such was the case between the two Bernoullis. As soon as John was settled professor of mathematics at Groningen, all friendly intercourse between the two brothers was at an end. Regarding John as the aggressor, and provoked at the ingratitude which he exhibited, his brother James challenged him, by name, to solve the following problems:"

1. To find among all the isoperimetrical curves, between given limits, such a curve that, a second curve being constructed, having its ordinates any functions of the ordinates or arcs of the former, the area of the second curve shall be a maximum or a minimum. 2. To find among all the cycloids which a heavy body may describe in its descent from a point to a line given in position, that cycloid which is described in the shortest time possible. A prize of 50 florins was offered by James to his brother John, if he should solve these problems in the space of three months, and produce legitimate solutions in the course of a year; and if, at the expiry of these intervals, no solutions appeared, he promised to lay his own before the public. This challenge was willingly accepted by John, who began the investigation as soon as he received the subject, and soon com-

pleted the solution. Flattered with success, he ostentatiously declared, that, instead of three months, he had discovered the whole mystery in three minutes. He demanded the prize, and offered to give to the poor what had cost him so little trouble to gain. Unfortunately, however, for John, his solution of the isoperimetrical problem was erroneous. His brother published a notice, in which he came under three engagements: 1. To point out the method employed by his brother; 2. To expose its errors, whatever the method was; 3. To give a true solution of the problem. The boldness of this notice induced John to revise his solution; and, having found his mistake, which he ascribed to the hurry in which it was obtained, he sent a new solution, and again demanded the prize. In reply to this demand, James Bernoulli requested his brother to examine his new solution, as the pretext of hurry would be unavailing after a second failure; but John replied, that his solution was correct, and that his time would be better employed in making new discoveries. In a letter to Varignon, which was inserted in the *Journal des Sçavans*, with an additional notice, James Bernoulli attacked, with a good deal of ridicule and sarcasm, the solution of John, who read the letter with the utmost indignation, and lavished on his brother a torrent of the coarsest invective.

In order to put an end to this geometrical warfare, which had now degenerated into personal abuse, Leibnitz, Newton, and the Marquis de L'Hospital, were appointed arbiters; but they do not seem to have come to any decision on the subject. In 1700, James Bernoulli published, in a letter to his brother, the formulæ of the isoperimetrical problem without a demonstration, and invited him to make his own public. John was still ignorant of the defect of his own method; and so much was he convinced of its accuracy, that he sent it under seal to the Academy of Sciences at Paris, in February 1701, on condition that it should not be opened till the appearance of his brother's demonstration. In consequence of this, James Bernoulli published his solution separately at Basle, and also in the acts of Leipsic for May 1701, under the title of *Analysis magni problematis Isoferimetrici*. The fame which was acquired by this admirable specimen of mathematical genius completely silenced the pretensions of John Bernoulli for five years; but after the death of his brother, in 1705, he published his solution in the memoirs of the academy for 1706, as if he had thought his brother the only person who could detect the false principle upon which it was founded. After an interval of thirteen years, John Bernoulli discovered the source of his error. He ingenuously confessed his mistake; and published a new solution in the memoirs of the academy for 1718, which did not differ much from that of his brother.

In the year 1699, James Bernoulli was elected a foreign associate of the Academy of Sciences at Paris; and, in 1701, the same honour was conferred upon him by the Royal Academy of Berlin. The sedentary life which he led, and his intense application to study, brought upon him a severe attack of the gout, accompanied with a slow fever, which put an end to his life on the 16th of August 1705, in the 51st year of his age. He was married in the year 1684, and left behind him one son and a daughter, neither of whom seem to have inherited any portion of their father's genius. The son was bred to the profession of a painter. James Bernoulli was engaged, at the time of his death, in a

work entitled, *Ars Conjectandi*, or the art of forming conjectures concerning contingent events. It was printed at Basle in 1713; and contains a valuable treatise on infinite series, in which its author has given an admirable demonstration of the first case of the binomial theorem. This demonstration has been lately re-published in the third volume of the *Scriptores Logarithmici* by baron Masceres.

Bernoulli was of a bilious and melancholy temperament, and possessed great perseverance in surmounting difficulties. His genius, though of the first order, was not of that quick and versatile character which seizes a subject with instinctive penetration, and invents and discovers by a process almost intuitive. It was marked rather by an excess of caution. He proceeded with slowness and suspicion, afraid of error, yet resolved to avoid it, and even after success had taught him the extent of his own powers, and after the applause of all Europe had stamped immortality upon his name, he did not possess that confidence in his talents which is generally the most prominent qualities of flattered genius. When he challenged his brother John to the solution of the isoperimetrical problem, on which he had for a long time laboured, he acted with more confidence than he usually displayed; but his excessive caution gave him ample security against the chance of error. His brother John, on the contrary, whose genius was more acute but less profound, obtained his solution of the problem almost instantaneously. Without even revising his investigations, he gave them to the world, careless about the mortification which he afterwards felt when they were proved to be erroneous. In the keen dispute which this circumstance occasioned, the characters of the two brothers appeared in their natural colours. The cold defiance, the chastened severity, and the temperate sarcasms of the one, form a striking contrast with the thoughtless ostentation, the rude invectives, and the coarse raillery of the other.

The writings of James Bernoulli are very numerous, and have been collected and published in two volumes, 4to, at Geneva in 1744. The papers which he published in the memoirs of the academy, are, 1st, *Section indefinite des Aires Circulaires, en telle raison qu'on voudra, avec la maniere d'en deduire les Sinus, &c.* Mem. Acad. 1702, p. 58. 2d, *Demonstration Generale du centre de Balancement, ou d'oscillation, tiree de la Nature du Levier*, Id. 1703, p. 114. 3d, *Application de sa regle du Centre de Balancement, a toutes sortes de figures*, Id. 4th, *Demonstration du Principe de M. Huygens, touchant le Centre de Balancement, et de l'Identite de ce Centre avec celui de Percussion*, Mem. Acad. 1704. 5th, *Veritable Hypothese de la Resistance des Solides, avec la Demonstration de la courbure des Corps, qui font ressort*. Mem. Acad. p. 130.

Besides these he published no fewer than forty-seven papers in the *Acta Eruditorum* of Leipsic, mostly mathematical, though some of them related to pneumatics, and others to mechanics. He published also seven papers in the *Journal des Sçavans*, some of which had appeared in the *Acta Eruditorum*. See *Oeuvres de Fontenelles*, tom. v. p. 57. edit. 1767. *General Dict.* Lalande, *Bibliographie Astronomique*, p. 299. Montucla, *Hist. des Mathemat.* tom. ii. p. 355. 444. Bossut, *Essai sur l'Hist. Gen. des Mathemat.* tom. ii. p. 30. *Athene Rauricæ. Atlumbratio eruditorum Basiliensium celeberrimum, 4th us Rauricis addita*, Basil, 1780, 8vo. (β)

BERNOULLI, JOHN, the tenth son of Nicholas

Bernoulli, and the brother of James Bernoulli, was born at Basle, in Switzerland, on the 27th of July, O. S. 1667. In the year 1682 he began his academical studies, and was soon afterwards sent to Neuchâtel, to prepare himself for those commercial pursuits for which he was intended by his father. The early development of his brilliant talents, seconded by an ardent thirst for knowledge, gave a new direction to his father's plans, who henceforth determined to form the mind of his son for those noble pursuits in which nature had destined him to engage. He was received master of arts at the age of eighteen; and on this occasion he defended a Latin thesis *De igni lambente*, and likewise a thesis in Greek verse. The study of medicine now occupied his attention; but though he prosecuted this subject to such a length as to compose and defend in public a thesis *De effervescencia et fermentatione*, in 1690, his mind was gradually turning to that sublime science, in which his brother had already acquired such distinguished fame. Under the guidance of that illustrious mathematician, he made rapid advances in the higher geometry, and was soon enabled to illustrate the new calculus which Newton and Leibnitz had discovered. About the end of the year 1690, John Bernoulli set out for Geneva; and, in the course of his journey, he nearly lost his life by a dangerous fall from his horse. In that seat of learning, he formed an intimacy with many of its most distinguished citizens, and particularly with Messrs Fatio, who were then celebrated for their mathematical acquirements. From Geneva he went to France; and having reached Paris about the year 1691, he was introduced to the Marquis de L'Hospital, Malebranche, De la Hire, Varignon, and the two Cassinis. He spent some time at the country house of the Marquis de L'Hospital near Blois, and such was the friendship which subsisted between them, that he instructed his host in the differential calculus, and composed for his use *Leçons de Calcul differential et integral*, which is published in the third volume of his works. Varignon was likewise initiated into the new geometry by the Swiss mathematician; who soon enjoyed the satisfaction of seeing these distinguished pupils ranked among the first analysts of the age. In the year 1692, he returned to his native country, where the loss of the brilliant society of Paris was compensated by a constant correspondence with Leibnitz, which continued till the death of the latter in 1716. Being about to enter into a matrimonial connection, he was prevented by this and other causes from accepting the professorship of mathematics at Wolfenbuttle, which was offered him in 1693. The degree of doctor of medicine was about this time conferred upon him, after having defended a thesis on muscular motion. His marriage took place on the 6th March, 1694; and, in obedience to the solicitations of the university of Gronigen, in 1695, he accepted the professorship of experimental philosophy, in which he was installed on the 28th of November. In this new situation his fame began to extend itself with unusual rapidity. The learned societies of Europe were proud to adorn their lists with his name, and sovereigns themselves felt an accession to their greatness by honouring him with marks of royal favour. He was elected a foreign associate of the Academy of Sciences at Paris in 1699, along with his brother. The Academy at Berlin chose him a member in 1701. He was introduced into the Royal Society of London in 1712; into the Institute of Bologna in 1724; and into the Im-

perial Academy of Sciences at St Petersburg in 1725. His invention of the luminous barometer, or of the mercurial phosphorus, arising from the friction of mercury upon glass in a partial vacuum, was shewn by Leibnitz to Frederick I. of Prussia, who presented Bernoulli with a golden medal of the weight of forty ducats.

In 1671, John Bernoulli solved the problem of the catenary curve along with Leibnitz and Huygens, though it is generally supposed, that this solution was partly the work of his brother. In 1697, he published his first essays on a new branch of analysis, to which he gave the name of the Exponential Calculus, which consists in differencing and integrating exponential quantities, or powers, with variable exponents. Leibnitz and John Bernoulli made this important discovery, without any communication, in 1694; but we are indebted to Bernoulli for a complete explanation of the rules of the calculus, and the purposes to which it might be applied. About the same time, he directed the attention of mathematicians to the celebrated problem of the *brachystochronon*, which consisted in finding the curve, along the concave side of which a heavy body would descend from one point to another in the least time possible, the line joining the two points being inclined to the direction of gravity. This difficult problem, which Bernoulli himself had solved, was also resolved by Leibnitz on the very day on which he received it. These two mathematicians determined to conceal their solutions for some time; but before they were published, sir Isaac Newton, the marquis de L'Hospital, and James Bernoulli, succeeded in demonstrating, that this curve, called the curve of quickest descent, is a reversed cycloid. While employed on this subject, James Bernoulli was led to the subject of isoperimetrical problems, which occasioned those differences with his brother which we have already related in the preceding article.

The problem of orthogonal trajectories, which Leibnitz had proposed to the English geometers, was completely resolved by John Bernoulli in the *Leipsic Transactions* for 1718. Sir Isaac Newton had brought the problem to an equation, but did not succeed in resolving the differential equation of the trajectory. Two particular cases of it were solved by the two Nicholas Bernoullis, the son and nephew of John. A better solution, though defective in point of generality, was given by Dr Taylor in the *Philosophical Transactions* of 1717; but it was left for John Bernoulli to supply this radical defect. This celebrated geometer succeeded, also, in the integration of several rational fractions, with which Taylor had endeavoured to perplex him.

The publication of Dr Taylor's method of increments gave rise to hostilities between him and John Bernoulli, more serious than the war of problems in which they had been engaged. Taylor was charged as a plagiarist in the *Leipsic Transactions* for 1716. This anonymous attack from the pen of John Bernoulli was indignantly repelled by the English geometer, who accused his antagonist of having only altered and modified the solution of isoperimetrical problems, which were given by his brother James. Bernoulli again retorted under the concealed name of Buscard; but his reply was stained by a species of angry invective, and insulting raillery, which was unworthy of a philosopher.

In a dissertation on *Orthogonal Trajectories*, published as the joint production of John Bernoulli and his son Nicholas, they proposed the problem of reciprocal trajectories, which was for a long time discussed between

John Bernoulli and Dr Pemberton. The friend of Newton carried on the controversy under an anonymous disguise; but he was unequal to a contest with such a formidable rival. Irritated at the success of Bernoulli, the English geometers assailed him in every quarter. Dr Keil challenged him to determine the curve described by a body when projected through a medium whose resistance varied as the square of the velocity. In a short time the exertions of Bernoulli were crowned with success; and though Newton had solved only the case where the resistance varied as the square of the velocity, the Swiss geometer determined the path of the projectile, when the medium resisted, according to any power of the velocity. Intoxicated with success, Bernoulli demanded the solution obtained by Keil, but when he found there was none to produce, he attempted to punish the presumption of the English philosopher, by the rudeness and severity of his wit.

The problem of Offenburgh, which consisted in determining on the surface of a sphere, curves whose perimeters could be expressed by algebraic quantities, had been tried in vain by Herman, (*Act. Petrop.* 1726): but John Bernoulli pointed out the error of Herman, and gave a general method for finding the curves required.

In the *Memoirs of the Academy of Paris* for 1730, he published his determination of the isochronous curve. In the same year, he carried off the prize of the Academy of Sciences, on the spheroidal figure of the planets, and on the motion of their aphelia; and in 1734, he shared the prize with his son Daniel, for a dissertation on the change of inclination in the planetary orbits; an occasion, as will be seen in the following article, which did not exhibit his character to the greatest advantage. His work on the management of ships, was published in 1718, and on this subject he was led into a controversy with Renau. In 1743, he collected together the various works which he had composed, and printed them at Lausanne, in four volumes quarto.

While our author held his professorship at Groningen, the university of Utrecht was solicitous to rank him among its members. His salary and appointments, however, were increased, and he continued in his office at Groningen, where a violent fever had nearly terminated his labours in 1704, till the pressing entreaties of his relations had almost induced him to return to Basle. The rumour of his departure incited the university of Utrecht to make another effort to obtain the benefit of his talents; and while he was hesitating what step to take, the death of his brother put an end to his irresolution. He returned to his native city, and succeeded his brother in the professorship of mathematics on the 17th of November 1705, where he delivered a discourse *De Fatis Novæ Analyseos et Geometriæ sublimis*. In this new situation he spent forty-two years of his life, which were zealously devoted to the discharge of his professional duties, and to the improvement of the mathematical sciences. He took an active share in promoting the objects of public instruction in his native city, and he had the honour of being twice rector, and nine times dean of the faculty of philosophy in the university of Basle. These professional labours he occasionally relieved by an epistolary communication with the first philosophers of the age; and he could number among his correspondents the names of Newton, Leibnitz, Marquis De L'Hospital, Euler, Maupertuis, Wolff, De Moivre, Mairan, Montmort, Renau, Tschirnhausen, Michelotti, Craig, Cheyne, Poleni, Cramer, Bulfinger, and Gravesende.

His correspondence with Leibnitz is published in a work in two volumes quarto, which appeared in 1745, under the title of *Leibnitii ac Bernoulli Commercio Philosophicum et Mathematicum*, and which contains much curious information respecting that campaign of problems, in which these powerful combatants shone with such distinguished lustre.

Near the close of the year 1747, he was attacked with a disorder in the bowels, which was not however sufficiently violent to interrupt his usual studies; but on the last night of the year, the disease reached such an alarming height, that he expired on the morning of the first of January 1748, in the eighty-first year of his age.

John Bernoulli had nine children, three of whom, (viz. Daniel, the subject of the following article: John, who was doctor of laws and philosophy, and professor of mathematics at Basle; and Nicholas, who was professor of law at Bern, and afterwards professor of mathematics at Petersburg,) inherited the genius of their father.

The talents of John Bernoulli as a mathematician were of the very first order; and if they were surpassed by any of his cotemporaries, the superiority could be claimed only by his brother and Sir Isaac Newton. He is represented by those that knew him, as just, sincere, and pious, possessed of much natural vivacity, and animated by a zeal and enthusiasm which often rose to extravagance.

In the angry contention which he carried on with his brother, we do not perceive any of those virtues which posterity can be called to admire. In the violence of his temper, and in the intoxication of success, we may find some apology for the vulgar sarcasms which he lavished upon Taylor and Keill; but the rude abuse which he poured upon a brother, superior to himself both in age and acquirements, and to whom he was indebted for all his mathematical knowledge, and the unnatural jealousy with which he viewed the rising reputation of his son, will long continue to cast a shadow upon his name, and must be permitted to remain upon record without either pardon or palliation.

During the whole of his life, he testified a sincere belief in the Christian religion, the doctrines of which he had studied with peculiar attention; and in a journal of the principal events of his life, which he left behind him, there are numerous expressions of the warmest gratitude for the kindness which the Almighty had shewn him. During his stay in Holland, his orthodoxy was called in question by the Dutch Theologians; and he published several polemical dissertations in defence of his tenets, and particularly an apology *pro sua fama, honore et religione*, which he pronounced as rector of the university. The controversy terminated in favour of Bernoulli; and the arm of the civil power was stretched out to silence his adversaries. (β)

BERNOULLI, DANIEL, a celebrated mathematician and natural philosopher, was the son of John Bernoulli, and was born at Groningen on the 9th of February 1700. The attention of young Bernoulli was early directed by his father to the study of mathematics; but his first attempts, though promising and successful, did not obtain that encouragement and applause which a son might have expected from the fond partiality of a father. Having one day received a problem to resolve, he carried it into his closet, examined it with attention, and returned with the solution to his father, delighted with the success of his first efforts, and anticipating the praise which they deserved. Why did you not resolve it instantly?

was the only answer he received; and the tone and manner in which it was spoken produced a temporary dislike to the mathematical sciences. Having refused to follow the profession of a merchant, to which he was destined by his friends, he entered upon the study of medicine, and went to Italy to perfect himself in that important science, under the care of Michelotti and Morgagni. His time, however, was chiefly occupied with mathematical pursuits; and he returned to his native country loaded with literary honours, alter having refused, at the age of 24, the presidency of an academy which the republic of Genoa was about to establish. In the following year he accepted an invitation to the Academy of St Petersburg; and though he enjoyed, in this situation, a handsome income, his affections were perpetually fixed on his native country: He therefore determined to leave Russia; but the court of St Petersburg, unwilling to suffer such a loss, increased his appointments, and settled upon him, during life, the half of his income, with permission to retire. This generous conduct, so seldom to be met with in the history of princes, induced Bernoulli to remain in Russia, till the loss of his health compelled him to return to the south of Europe. In 1733, when he arrived at Basle, the residence of his father, he was appointed professor of medicine, and afterwards filled the chair of physics, and of speculative philosophy, which he held at the same time.

The first work published by Bernoulli appeared in 1724, under the title of *Exercitationes quædam Mathematicæ*. This interesting production, which was printed in Italy with the approbation of the Inquisition, contained an able solution of the celebrated equation of Riccati, and several ingenious observations on recurring series, which conducted him, a few years afterwards, to a new and elegant method of approximation, for determinate equations composed of an infinite number of terms.

His attention was next directed to mathematical subjects, upon which he published several ingenious and profound memoirs. In the Commentaries of St Petersburg for 1726, he gave the most complete demonstration of the parallelogram of forces. This demonstration, though long and abstruse, was independent of the consideration of compound motion, and consisted chiefly in proving the absurdity of every other supposition. His memoir on the relation of the centre of gravity, the centre of oscillation, and the centre of forces; his researches respecting the oscillatory motion of a system of bodies placed along a flexible thread; and his determination of the direction and velocity of the two motions,—display a genius of the first order, and have greatly contributed to the advancement of theoretical mechanics. His papers on these subjects will be found in the *Comment. Petrop.* vol. vi. p. 108.; vol. vii. p. 162.; vol. ix. p. 189.; vol. xv. p. 97.; vol. xviii. p. 245.

The problem of vibrating chords, which was partially solved by Taylor in 1714, and afterwards in a more general form by D'Alembert and Euler, by means of their new calculus of partial differences, was the next subject that employed the genius of Bernoulli. He attempted to shew, that the method of Taylor, though limited by the particular hypothesis which he employed, was as general in its nature as that of D'Alembert and Euler, who had only the merit of employing a new analysis. By considering the decomposition of the real motion of a string into the isochronous vibrations of the whole string and its aliquot parts, he obtained a solution of the problem as extensive in its application as that which can

be fairly drawn from the methods of D'Alembert and Euler. From this solution he afterwards deduced the lateral vibrations of an elastic rod fixed at one extremity; and investigated the vibrations of a column of air impelled with different degrees of force and velocity; and the results of his researches were found to accord with the most accurate experiments. His memoirs on these subjects will be found in the *Mem. Acad. Par.* 1762, p. 442. *Comment. Petrop.* tom. iii. p. 13, 62.; tom. xiii. p. 105, 167. *Nov. Com. Petrop.* tom. xv. p. 362.; tom. xvi. p. 257.

In the year 1746, Bernoulli discovered a new principle in dynamics, called the *Conservation of the momentum of rotatory motion*, of which he published an account in the memoirs of the academy of Berlin for 1746. The same discovery was made nearly about the same time by Euler and the Chevalier d'Arcy.

The only separate work of any magnitude which was published by Bernoulli, appeared in 1738, under the title of *Hydrodynamica, seu de viribus et motibus Fluidorum commentarii*. The theory of the motion of fluids having hitherto been treated in a vague and unphilosophical manner, it was reserved for Bernoulli to lay the foundation of a new theory, more conformable to experience. He supposed, that the surface of a fluid, discharging itself through an orifice, always continued horizontal; and that all the points of the elementary horizontal strata, into which the fluid mass is conceived to be divided, descend vertically, with velocities inversely proportional to the horizontal breadth of the strata to which they belong. By employing the principle of the conservation of living forces, he determined the motion of the strata with such elegance and address, that the Abbé Bossut pronounces the work which contains them to be one of the finest specimens of mathematical genius. A more direct theory, however, was afterwards given by Maclaurin and John Bernoulli; but it is to D'Alembert that we are indebted for a complete theory of the equilibrium and the motion of fluid bodies.

The curious and important subject of probabilities occupied much of Bernoulli's attention. After laying down a new principle instead of that which was employed by Fermat, Pascal, Huygens, and James Bernoulli; he applied it to the subject of inoculation, to the observations of practical astronomy, to the irregularities in the motion of time-pieces, and to some subjects of political economy.

Bernoulli had the high honour of gaining ten academical prizes, which he disputed with the most illustrious geometers of Europe. At the age of 24 he carried off the prize for the best construction of a clepsydra for measuring time at sea; and in 1754, he divided the prize with his father for the best explanation of the variation in the inclinations of the planetary orbits. His father could not conceal the mortification which he felt at being thus brought down to a level with his son. The love of glory was the ruling principle in his heart; and all the feelings of a father and a man were instantly extinguished when they came in competition with his reputation as a philosopher. The reproaches with which he loaded his son might have found some palliation in the irritability of his temper, when the judgment of the academy was first pronounced, but no apology can be offered for the permanency of a resentment so unnatural and unmanly. Never, perhaps, was there a case in the rivalry of talents that afforded such an opportunity for the finest exhibition of feeling, and for the noblest

display of character; and never, perhaps, was there a case in which genius appeared in such an offensive and mortifying form. While the exultation of youthful genius ought to have been tempered in the one by filial regard, a paternal pride ought to have animated the other, and the father ought to have gloried in having transmitted to his son the full inheritance of his genius, without having impaired or resigned the original possession.

In 1740, Bernoulli divided the prize on the subject of tides with Euler and Maclaurin; and in this and the preceding dissertation he supported the Newtonian theory, which his father and his uncle had uniformly endeavoured to overturn. He carried off also the prize which was offered in 1743, for the best treatise on the mariner's needle. In 1747, he divided with an anonymous author, the prize for finding the time at sea when the horizon is invisible. His dissertation on currents gained the double prize in 1751; and in 1753, he was rewarded with the prize for the best method for supplying the action of the wind in large vessels. The last reward which he gained, was the prize for diminishing the rolling and the pitching of vessels, without injuring their other qualities. In the year 1748, he succeeded his father in the Academy of Sciences; and such was the extent of his fame, that he was elected a member of the Royal Society of London, of the Institute of Bologna, and of the Academies of Petersburg, Berlin, Turin and Mannheim.

Though Bernoulli possessed a delicate constitution, yet the regularity of his life, and the serenity of his temper, exempted him from those diseases to which he might otherwise have been subject. During a long life of 83 years, he retained the complete use of all his faculties, and the last of his works exhibits the same profound genius which marked his earlier productions. For some years before he died, he withdrew himself from the fatigues of society, and associated only with a few select friends, with whom he had been long connected. The attack of an asthma, however, began to impair his strength, and at last carried him off on the morning of the 17th of March 1782, when he was found dead in his bed.

Daniel Bernoulli was distinguished in private life by his simple and unassuming manners, which were neither marked by false diffidence, nor affected austerity. He was charitable and humane without ostentation; and though his affairs were managed with that laudable economy which shuns the expenses of an idle vanity, he was never guilty of that avarice which some of his enemies have endeavoured to fix upon his name. Actuated by a love of peace, or warned perhaps by the fatal example which was exhibited in the conduct of his father and his uncle, his life was never embittered by those malignant dissensions which generally rage among men of genius. The humour which is occasionally displayed in some of his controversial writings, is a proof that the tranquillity which he enjoyed, was more the offspring of reason than of insensibility. Possessed of such qualities, the friendship of Bernoulli was courted by the wisest and the most virtuous of his fellow citizens; his advice even upon public affairs was implicitly followed; persons of all ranks in Basle bowed to him as they passed, and the first lesson which a father taught his child, was to pay the usual respect to the aged philosopher. The regard which he showed for religion, both in his writings and his conduct, might have saved his name from the unjust suspicion of infidelity; but it is the lot of ge-

nus and virtue to suffer this unmerited odium, and though Bernoulli knew that the orthodox ministers of Basle accused him of thinking too freely, he never attempted either to confirm or to repel their charges.

Although Bernoulli was not insensible to the high fame which he enjoyed, he often related to his friends two adventures, which he remembered with more pleasure than all the honours with which he had been loaded. When travelling with a learned stranger, who was much pleased with his conversation, his companion took the liberty of asking him his name. "I am Daniel Bernoulli," replied the philosopher. "And I am Isaac Newton" returned the stranger; who felt indignant that a man so young and so simple in his manners, should counterfeit the name of one of the greatest philosophers in Europe. On another occasion, when the celebrated Koenig was dining at his house, Koenig spoke to him with much self-satisfaction about a problem, which, after great labour, he had succeeded in resolving. Bernoulli continued to do the honours of the table, and before they rose from it, he presented Koenig with a solution more elegant than his own.

A more detailed account of the life and writings of Daniel Bernoulli, will be found in his eloge by the Marquis de Condorcet, and in the history of the different sciences which his genius has illustrated. (β)

BERRY, the name of a province of France before the revolution, which is now comprehended in the two departments of Cher and Indre; the former containing what was called Higher Berry, and the latter what was called Lower Berry. See CHER and INDRE. (j)

BERTIERA, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY. (sv)

BERWICK-UPON-TWEED, so called to distinguish it from North Berwick in East Lothian, is an English town of some importance, situated on the north side of the river Tweed, and within one mile of the sea; in N. Lat. $55^{\circ} 16' 40''$. W. Long. $2^{\circ} 3'$ from Greenwich.

In Domesday-book, *Berwica* is used to denote a grange or farm village belonging to some town or manor; and is equivalent to *Bere-tun* or *Bar-ton*, still having that signification in Devonshire, and other parts of England. Chalmers, the learned investigator of Scots antiquities, hesitates between the former etymology and the Anglo-Saxon *Bar, nudus*, bare; and *Wic, vicus, castellum, sinus*; a village, castle, or curving reach of a river. See Chalmers' *Caledonia*, ii. 198, 199.

The river Tweed is navigable to this place, and although there is good depth of water close to an excellent quay, even at the lowest ebb, yet, from a bar at the mouth of the river, and a shallow called the ford at some distance below the quay, the port can only be entered by vessels of small draught. From the convenience of its harbour, Berwick enjoys a considerable coasting trade, and used to import timber, iron, and flax from Norway and the Baltic. But its principal dependence is upon the export, coastways, of large quantities of excellent salmon to London, sent fresh in boxes stratified with ice, and the distribution of the surplus farm produce of Berwickshire, Tiviotdale, North Durham, and the northern part of Northumberland, to other parts of the kingdom; having sometimes shipped in one year 60,000 quarters of grain, near 2000 packs of wool, eggs to the value of 20,000*l.* and great quantities of salmon, the fisheries of which bring in more than 10,000*l.* yearly.

Berwick, formerly belonged to Scotland, and was one of its four principal boroughs, the representatives of

which, with the chamberlain of Scotland, formed a court for determining commercial questions. But it has been long annexed to England, along with a triangular territory reaching about four miles up the river Tweed, and nearly as much along the sea, containing from four to five thousand acres of useful farm land.

This place is governed by a mayor and four bailiffs, who constitute the sheriff. The mayor, recorder, and justices, or all who have been mayors, hold general and quarter sessions, and a court of gaol-delivery at one or other of the quarter sessions, when necessary. The guild or corporation consists of the mayor and all the burgesses, nearly a thousand, in whom are all elections, and the entire management of a very valuable landed property within the bounds, the far greater part of which they divide among themselves, instead of applying to great and useful public purposes. In 1796, the population was estimated at 7930, and had probably doubled in the preceding 50 years; it is now somewhat above 8000, including a very small number of agricultural inhabitants in the liberties.

Berwick was regularly fortified on the old Spanish or Italian system, in the reign of Mary, Queen of England, and has five demi-revetted bastions, with double retired flanks, casemates, and cavaliers; but the ditch is very shallow, and has either never been revetted, or the counterfort is now ruined and obliterated. The ruins of the ancient Scots fortifications, and of a very extensive castle, are still obvious. But in the present art of war, no fortifications around this place could ever be important, as it is every where closely surrounded by commanding eminences, and hollow ways reach almost up to the walls, forming natural approaches.

About the year 1770, in excavating a foundation in one of the streets of Berwick, called Hide-hill, considerable quantities of clay were dug out, which was intimately mixed with quicksilver in small globules, insomuch, that from one piece about the size of an egg, nearly a tea spoonful of pure quicksilver was collected. But before this discovery was made, most of the clay had been thrown away; and the mineral spot being situated in the middle of the town, it was not advisable to prosecute the search. (κ)

BERWICKSHIRE. This county is situated at the south-east extremity of Scotland, on the shore of the German or British ocean, and adjoins the north-east border of England, deriving its name from the town of Berwick-upon-Tweed, which was formerly its head borough or county town; but which has been long annexed to the crown of England, though still enjoying a species of anomalous jurisdiction in some measure separate from both kingdoms of England and Scotland. Berwickshire is bounded on the east by the German Ocean, and a part of the mouth of the Firth of Forth. It bounds on the north with East Lothian, mostly along the range of hills called Lammermoor, having, however, one parish to the north-east of these hills, situated on the extreme south-eastern angle of the vale of Lothian. On the west, it joins partly with Mid-Lothian to the north, but principally with Roxburghshire. The southern boundary is formed by the river Tweed, dividing it from Roxburghshire on the west, Northumberland in the middle, and North Durham on the east: but a portion of Roxburgh in the neighbourhood of Kelso, and the township of Berwick, are both on the north side of this river.

Dunse, nearly in the centre of the shire, is its principal town, and is in W. Long. 2° , N. Lat. $55^{\circ} 49'$. The

most easterly point where this shire joins Berwick township is in W. Long. $1^{\circ} 41'$, and the western extremity in W. Long. $2^{\circ} 34'$. The most southern point on Tweed, is in N. Lat. $55^{\circ} 36' 30''$, and the most northern in N. Lat. $55^{\circ} 58' 50''$. The extreme length is $31\frac{1}{2}$, and the extreme breadth $19\frac{1}{2}$ statute miles; and the entire superficies of the county extends to about 285,000 English acres, of which about 100,000 are arable, and 185,000 are composed of moors and hill pasture.

Anciently Berwickshire seems to have included a considerable portion of the lowlands of Roxburghshire, as the old castle of Roxburgh or Rokesburghe, was formerly known by the name of March-mount, in reference to the ordinary term of the Merse or March, by which the lowlands of this county are still known. Lauderdale was formerly a separate regality, or higher and almost independent jurisdiction, under the name of a bailliary; and was a detached domain belonging to the powerful family of the lords of Galloway, which ended in the inglorious John Baliol, and his gallant but unfortunate kinsman, John the Red Cumyn, who was slain by Robert the Bruce. Lammermoor is the north eastern hill district of this county; having Lauderdale on the west, and the Merse on the south and south-west. Besides these large divisions, the county is divided into three presbyteries, Chirnside, Dunse, and Lauder; and these are subdivided into thirty-one parishes.

The mountainous districts of Lammermoor and Lauderdale are of considerable extent, in which the general range runs inland from the sea at St Ebb's Head nearly west; but intersected by many narrow vales in various directions, chiefly tending towards the south, in which most of the streamlets flow; though the rivers of the vale land principally run from west toward the east. From the main range of hills, various spurs jut out towards the south; and there are several detached or isolated hills in different places of the vale of the Merse: And even that vale is much diversified by numerous swells and knolls, and winding deep dells, in which last the streamlets of the lower country flow in search of the larger waters and rivers. The northern sides of the Lammermoor hills are of considerable steepness, but belong to East Lothian; while the southern slopes are generally moderate, and blend gradually into the lower vale. In many places the tops of the hills form extensive elevated table lands, which slope almost insensibly towards the south into the lower vales. The higher land is usually miserably bare infertile moor; while the slopes, called the moor edges, are mostly useful land, and sometimes of excellent quality. Two of the table lands are crossed by the principal great roads leading from Edinburgh to Berwick and Kelso; one at the Press inn, called Coldingham moor, once a royal forest; the other at Blackshiels. But the oryctology, or features of the country, have hardly been attended to in any survey of the country, and cannot be satisfactorily described by any person who has not carefully travelled the country for the express purpose. Clint-hill, at the north-west extremity of the Lammermoor chain, is said to be 1544 feet above the level of the sea. The general range may average about 1000 feet, declining as it approaches towards the sea and the east; and the whole terminates in three precipitous rocky promontories, at St Ebb's Head on the south, Earn's Cleugh in the middle, and Fast castle on the north. St Ebb's Head is detached from the extremity of the chain, by a deep narrow dry dell, almost level with high water-mark at spring-tides.

There is only one small lake or loch near Coldingham, of no moment. The Tweed, though it skirts Berwickshire in a winding course of forty miles, can scarcely be considered as belonging to the county, as no portion of its territory crosses that fine stream, and its rise is at a great distance in the west of Tweed-dale or Peebles-shire. Whitadder and Blackadder are the principal rivers of the county, though the former rises in East Lothian; and both united run into Tweed near Berwick. Leeder or Leader, entirely belonging to and giving name to Lauderdale, runs from north to south, and falls into the Tweed at the south-west corner of the county. Eden, which rises at the west end of the Merse, runs into Tweed in that part of Roxburghshire which lies on the north side of this river, usurping, as it were, a valuable portion from the Merse, which probably, in ancient times, formed a part of the constabulary of Roxburgh Castle or Marchmount; a separate jurisdiction independent of the adjoining sheriffdoms. The Eye, a small water, or large burn, is the only stream of any consequence in the county which runs directly into the sea.

This is by no means a mineral district. The general run of the rocks and lower hills is composed of most irregularly stratified schistic stone, or hardened clay, with yolks of whin-stone, and quartz veins, mostly very thin and irregularly branching, but much mixed with a kind of steatitic half lapidified substance, called *leck* by the quarriers. In the higher muirs, there is a good deal of amorphous and splintery trap, or bastard whin-stone. In several places there are rocks of breccia, or coarse pudding-stone, many of which are in small fragments; but a remarkable instance occurs in the rocky cape or promontory covering Eyemouth bay on the north-east, which is composed of large nodules of whin and schist, of great varieties of size, form, and colour, imbedded in lapidified clay, somewhat like steatite, of various colours, often greenish, generally very hard and tough, but soapy to the feel. This stone is very durable, even when exposed to the stormy waves of the German Ocean, as is manifest both by the mother rock, and by Eyemouth outer pier, which has stood the raging of the sea uninjured for above thirty years. In many places there is abundance of stratified silicious sand-stone, usually called free stone, much of which is coarse grained, yet useful in building; though in some places it is found of very fine grain, and beautiful in colour and texture, standing the weather admirably. No coal has yet been found worth working in the county; and, indeed, the only seam yet discovered is at Lamberton, of which there are various rumours, none of which are worthy of being mentioned for want of full and authentic information. At Ordwell, on the Whitadder, an attempt was made, many years ago, to dig for copper ore, and the gallery or mine is yet open and accessible for a considerable way. The writer of this account could never procure any report on this subject worth listening to, and he only knows that it was abandoned long ago. Agricultural reports have now been procured of all or most of the counties and districts of our country; and it were perhaps worth national encouragement, to employ scientific mineralogists and geognosts to examine deliberately and to report upon the probability of our subterranean riches.

Berwickshire is noted as an agricultural district of peculiar excellence in its general system of management, which consists in judiciously blending together the cul-

tivation of grain and grass alternately, or what is usually called the *convertible agriculture*. In this plan, a portion of every arable farm, usually about half, is in pasture, appropriated for the breeding and feeding of cattle and sheep; while the remainder is under aration, for the production of turnips, ruta baga, and hay, as winter provender for the stock, and grain of all the usual kinds for sale; and these are regularly and progressively interchanged. One remarkable excellence of this system, where it is not hampered by injudicious covenants in leases, is that in any turn of markets in favour of stock or grain, or the contrary, the farmers can suddenly take the advantage of the change by extending the branch which promises profit, and curtailing the other. But the limits of an article like the present does not admit of extending our remarks on this subject, which will be found detailed in the agricultural report of the county.

All farms in this county are held under regular leases, mostly for nineteen years' endurance, sometimes more, but seldom in those recently granted, and a few shorter. By these the farmers stipulate to pay a certain money rent yearly, hardly ever a grain rent, and there are no personal services or bondages. The rental amounts paid by farmers must, of course, vary according to the value of the lands. But the farms taken within the last six years, in good situations as to manure and markets, and of tolerably good soil on the average, have been let at from one pound to thirty shillings, two guineas, and even up to three guineas and four pounds eleven and sixpence, the English acre; which, for the Scots, are respectively $1l. : 5 : 6$, $1l. 18s. 2l. : 13 : 4$, $4l.$, and $5l. : 16 : 4$. But there is every reason to suspect that at least the extreme rents in the foregoing enumeration are beyond the golden mean; especially considering that Berwickshire contains no carse soil, and even, generally speaking, its soil is far from being of a deep and substantial nature, except around towns and villages, having only been manured since the cessation of the border wars; before which most of it lay in waste pasture, or under the miserable deteriorating system of lee and runrig.

This is entirely an agricultural or rural district, and has no manufactures worth mentioning, except that of paper; for which there are three mills in the county. Broomhouse paper-mill near Dunse having eight vats; Ayton paper-mill five; and Chirnside or Allanbank paper-mill two. There is nothing which can be called commerce at the only sea-port in the county, Eyemouth; excepting that one corn merchant exports coastwise from this place a good deal of the surplus grain produce of the county; and here likewise coals and lime are imported for the supply of the eastern inhabitants. Berwick still remains the chief commercial harbour of export and import for the whole county. There are several fishing villages of small importance, the inhabitants of which are principally engaged in the white fishery, chiefly for the Edinburgh market. The salmon fishery of the Tweed belongs principally to the township of Berwick, and the opposite English shore of that river; and the trade of salmon exclusively to the London market, sent fresh and packed in ice, centers entirely in that town.

In 1795, the rental of the county was estimated at 112,000*l.* In 1800, at 118,000*l.* In 1806, at 210,000*l.* And in 1808 for the property tax of 1807, at 226,000*l.*

One striking instance of the progressive rise in the value of land is worth recording. About sixty years ago, a farm of 300 English acres was sold for 950*l.* Its progressive rents were in successive leases of nineteen years, several of which merged into new bargains before they expired: 37*l.*, 50*l.*, 100*l.*, 400*l.*, and 615*l.* It was sold a few months ago for very near 20,000*l.*, though six or seven years of the last lease have to run; and during the whole period of sixty years, the landlord has been at no expense whatever in ameliorations or improvements, neither does the farm possess any peculiarly good soil, or any remarkable advantages, except nearness to market.

In 1755, by the returns made to the celebrated Dr Webster, the population of the county was 24,946. In 1794, as made up for the Statistical Account of Scotland, it was 30,875. And in 1801, under the population act, the numbers were 30,529. The diminution, only 346, may be more than accounted for by the drain of men for the navy, army, and militia. Berwickshire contains $\frac{1}{17}$ of the whole extent of Scotland; $\frac{1}{5}$ of the population, $\frac{1}{21}$ of the valued rent; and pays $\frac{1}{9}$ of the real rent of the kingdom. In 1783, its whole taxes to the state and the county rates were 2539*l.* In 1801, eighteen years later, they were 18,447*l.* In 1807, 44,514*l.*

This county formed a portion of the Roman province of Valentia, and was inhabited by the ancient British nation called *Outadini*, and many hill forts of the former inhabitants are to be found on its numerous eminences, interspersed with a few Roman camps. One singular remnant of antiquity, called *Herritsdyke*, may be traced in an oblique direction almost through the whole extent of the county, from a camp or hill fort, on Hareffaulds in Lauderdale, to the banks of the Whitadder near the Tweed, a distance of twenty-three miles in a strait line; which seems to have been intended as a defence against the sudden incursions of the neighbouring barbarous tribes. Home-castle and Fast-castle, present ruins of the only border fortresses of any importance. There was formerly a castle of considerable magnitude at Ayton, of which not a vestige remains; and there have been numerous towers, peels, and smaller castles in various places, for the defence of the country in the long wars between England and Scotland, to which this county was much exposed from its border situation. On a flat elevated rocky peninsula close to Eyemouth, still called the *Fort*, there are very distinct remains of a regular fortification of the more modern kind, forming a crown-work across the gorge, which joins this peninsula to the main land. This was the work of a French engineer during the minority of the beautiful and unfortunate Mary; but the jealousy of the more powerful English government insisted upon its immediate demolition.

Besides Berwick, which does not now belong even to Scotland, the towns of this county are few and inconsiderable; Dunse, Coldstream, Greenlaw, Lauder, and Eyemouth, being all that are worth naming. For any particulars respecting them which deserve notice, see these articles in our work. The various parishes of the county will be found described in the *Statistical Account of Scotland*; and *Agricultural Reports of Berwickshire* have been published by Messrs Lowe, Bruce, Home, and Kerr. See likewise the *Cal-donia* of Chalmers, more especially for the antiquities of the county. (κ)

BESANCON, the *Visontio* of the ancients, a city of France, and capital of the department of the Doubs, is a beautiful town, embosomed in mountains, and situated on the river Doubs, which divides it into two towns; the upper and the lower, which are connected by a handsome bridge. The citadel, which is very strong by nature, is built on a sharp rock, and commands the city. The town has six gates, and is defended by a wall, flanked with eight towers. The lower town consists of three long and beautiful streets, the houses of which are built with freestone, and roofed with slates. The metropolitan church, the foundling hospital, the town house, and the governor's palace, are the modern buildings most deserving of notice. The remains of Roman architecture are still visible near the church of Notre Dame, where there are vestiges of a triumphal arch, erected by the emperor Aurelian in the year 274. The garden of the palace of Granville, is a favourite place of resort for the inhabitants; and the promenade of Chammaris is much frequented. The school of artillery has been long celebrated, and the town possesses a manufactory for swords and fire-arms, and a large establishment for the manufacture of clocks. The environs of Besancon are highly picturesque. The mountain of Cnaudane is richly covered with coppice wood. At a small distance from the town are warm baths, which are well frequented. At Ornans, about three leagues from Besancon, there is a well which sometimes inundates the fields, and throws up a kind of fish called *umbres*. The famous grotto of Aussel, which contains the most beautiful crystallizations, is about five leagues from the town. According to the *Bureau des Cadas-tres*, the population of Besancon is 21,572. Chantreaux makes it 30,000. East Long. 6° 2' 40", North Lat. 47° 13' 45". See *Mém. Acad. Par.* 1712, 1726, and DOUBS. (q)

BESLERIA, a genus of plants of the class Didynamia, and order Angiospermia. See BOTANY. (w)

BESSARABIA, a province of the Ottoman empire, bounded on the east by the Black Sea and part of Russia, from which it is separated by the Dniester; on the south by the Danube; and on the west and north by Moldavia, from which it is separated by a chain of mountains. The breadth of this province from Akerman to Gretscheny is nearly 170 versts, and its length from Staraya Gangura, at the confluence of the Botna and Botniza, is sixteen versts. The soil of Bessarabia is in general fertile, if we except a tract of land on the banks of the Danube and the steppe of Otschakov. The soil along the Dniester is in good cultivation, and supports a considerable number of orchards. Hemp and flax grow wild on extensive tracts of land, and the grass is in general seven or eight feet high. Near Tatar Bonnar are some salt water lakes, on the surface of which salt is formed by the heat of the sun. The revenue from this article, which once belonged to the Khan of Crimea, has been drawn by the Pacha of Ismail since the conquest of that country by the Russians. The fruits of this province are large and of the best quality. The cucumbers grow to an immense size. The plumbs of Akerman, the apricots of Ismail, the peaches of Babahda, are much superior to those in the south of Europe;

VOL. III. PART II.

melons and asparagus grow wild in the fields; and the grapes, which are of three kinds, afford a wine of superior quality.

The peasants of Bessarabia live on meal mixed with butter, fat, and milk, which is sometimes rendered more palatable by a few balls of boiled millet. Their bread is made of barley, and their drink is *braga*, a mixture of millet-meal and water, which becomes acidulous by fermentation. In every cottage there is a loom on which the women weave linen, a coloured stuff for gowns, and a kind of net-work used for veils. In the neighbourhood of Kauscher are quarries of granite, of which the Turks form their tomb-stones; and in different parts of the province there is a considerable quantity of lapis ollaris. Lizards and tarantulae are found here in great quantities.

This province was but partly subdued by the Romans, who had only one colony at Cœtia, now Kilia. Bessarabia is a Sandgiack or government, and the principal Sandgiack, who resides at Bender, has an annual revenue of three thousand pounds sterling. The principal towns are Bender, Ismail, Akerman, Kilia, and Kauscher. Bender is now the capital, though Kauscher was formerly the capital of the part of Bessarabia which belonged to the Khan of Tartary.

BETA, a genus of plants of the class Pentandria, and order Digynia. See BOTANY. (w)

BETEL, an Indian plant of the genus *figifer*, which is employed for the purposes of luxury and health among the oriental nations. The red juice which is pressed out of the leaves by mastication, renders the lips red, and the teeth black, and while it gives sweetness to the breath, it is said to strengthen the teeth and gums, and to be of great use in disorders of the stomach.

Every person keeps a box of betel, and presents it as we do snuff, as a mark of civility. It is often given as a present among the lower classes; and in parting with a friend, a purse of betel is generally presented as a token of remembrance. (q)

BETHESDA, the Hebrew name of a pool or pond in Jerusalem, near the sheep market. Jo. v. 2—7. The word *καταμαρμαρα*, which in that passage is translated *pool*, signifies a reservoir of water, deep enough to allow a person to swim in it. Formerly there were two pools of that description in Jerusalem, near the mount on which stood the temple; the one called the upper pool, (2 Kings xviii. 7.) and the other the pool of Siloam by the king's garden, (Neh. iii. 15.) in which our Saviour directed the blind man to wash for the recovery of his sight. (Jo. ix. 7.) Some interpret the word Bethesda as signifying a *drain*, because the water used for washing the entrails of the beasts which were to be offered in sacrifice in the temple flowed into it; to which circumstance they very absurdly ascribe a medicinal quality of the pool. But Bethesda has, with greater propriety, been understood to signify *the house of mercy*, as expressive of the mercy of God to his people in the healing virtue which the water of that pool possessed. The five porches mentioned by John, are believed to be the remains of five apartments for the accommodation of the great multitude, who came to the pool to be cured of their bodily diseases. And Maundrell tells us, that when he was at Jerusalem, he saw what was supposed to have been the pool of Bethesda, contiguous on one side to St Stephen's gate, and on the other, to the area of the temple. "It is," says he, "one

hundred and twenty paces long, forty broad, and at least eight deep; but void of water. At its west end it discovers some old arches now damm'd up."

"In these porches," says the Evangelist John, "lay a great multitude of impotent folk, of blind, halt, withered, waiting for the moving of the water. For an angel went down at a certain season into the pool, and troubled the water: whosoever then first, after the troubling of the water, stepped in, was made whole of whatsoever disease he had." Whether the miracles performed at the pool of Bethesda, were confined to the season of the particular feast mentioned in v. 1st, as the words *κατα καιρον* in v. 4th would seem to imply; or whether these words, taken in a more enlarged sense, may be explained to signify that the water had its sanative quality at other Jewish festivals, cannot be ascertained. That it had not that quality at all times, but only at certain times, when an angel went down and troubled, that is, agitated, the water, is clear from the words of the Evangelist.

In order to account, in a natural way, for the sanative quality of this pool, Hammond supposes that the water became medicinal in consequence of an impregnation from the blood and entrails of the sacrifices, conveyed thither by the water in which they were washed at the temple; and that by the *αγγελος*, who troubled the water, we are not to understand an angel, but only a messenger, probably a servant of the high priest, who might be sent at a particular season to agitate the pool. But that explanation is evidently contradicted by the narrative of the Evangelist. The Greek word, translated angel, is never used in the sense which that interpretation gives it, and it is evident, that had there been no divine agency, the virtue of the water would have been confined to the cure of some particular disorder, and would have been found in the water at one time as well as at another; the very reverse of which John tells us was the case. It cured all, but it cured only one person at one time, namely, the person who first stepped in, after the water was agitated by the descent of an angel. Of whatever use, therefore, this pool might have been in the earliest ages, certain it is that He, who is the sovereign physician of soul and body, made use of it, in the days of the Saviour, for the cure of diseases, in a way which must have convinced men that these cures were effected, not by a natural, but by a miraculous operation. For the true reason, why the virtue thus communicated to the water, by the descent of an angel, was effectual for the cure of only one person, at one particular time, was to manifest the miraculous nature of the cure. Tertullian informs us, that the water of this pool ceased to be beneficial to the Jews upon their obstinate perseverance in their rejection of Christ's divine mission; another proof that it derived its healing quality directly from the agency of the Divine Being, and lost it at the precise time when that divine agency was withdrawn. We may therefore conclude with the learned Dr Macknight, that Bethesda obtained its miraculous healing quality, in honour of the personal appearance of the Son of God upon earth. See *Ant. Univ. Hist.* vol. ii. 442.; vol. x. 344. Maundrell's *Journey to Aleppo*, p. 107. Stackhouse's *Hist.* vol. v. p. 393. Calmet's *Diet.* (A. F.)

BETHLEHEM, a city of Judah, generally called Bethlehem of Judah, or Bethlehem Ephratah, to distinguish it from another Bethlehem in Zebulun. Neither eminent for the number nor the wealth of its inhabitants, it became famous by being the birth-place of the

royal Psalmist, hence emphatically named the city of David; but still more so, by being chosen by Providence to give birth to the Saviour of the world. For that reason, though now reduced to the size of a village, it has always been regarded as a place of high renown; and at present can boast of a convent of the Latins, another of Greeks, and a third of the Armenians. But its chief ornament is a magnificent church, erected by the pious empress Helena, over the place where the Saviour was born; to which a great number of pilgrims annually resort. It is built in the form of a cross, and the top of it commands a fine view of the surrounding country. The roof is of cedar, covered with lead, and supported by four rows of lofty pillars, ten in a row, and each formed of one entire piece of white marble. The walls were overlaid with the same beautiful stone, but it is said that the Turks have carried it away to adorn their mosques. The upper ends of the cross terminate in three semicircles, in each of which there is an altar. Over the chancel is a large cupola, of which the outside is covered with lead, and the inside adorned with beautiful Mosaic workmanship. Here also is a cave, or grotto, hollowed out of a chalky rock, which is highly revered on account of a tradition, that in it the Virgin Mary hid herself and her child from the wrath of Herod, for some time before she and Joseph fled with him into Egypt. On the west side of the town there is a well, called the *Well of David*, on account of his extreme desire to drink the water of it; (2 Sam. xxiii. 15.) but it now resembles a cistern more than a well, being supplied only with rain water. About two furlongs beyond it, are still to be seen the remains of an old aqueduct, said to have been the work of Solomon, for the purpose of conveying the water from Solomon's pools to Jerusalem. It runs the whole way along the surface of the ground, and is composed of coarse marble stones, united together with a cement which has become even harder than the stones themselves. For the greater security, these were covered with smaller stones mixed with a strong mortar, so that the whole work seems to have possessed a durability sufficient to withstand the ravages of time. But this strong aqueduct, which at an immense labour and expence had been carried five or six leagues, has been so completely destroyed by the Turks, that only a few scattered fragments of it remain.

For an account of the present state of Bethlehem, we shall transcribe the short description which is given of it by Volney. "This village, situated two leagues south-east of Jerusalem, is seated on an eminence, in a country full of hills and vallies, and might be rendered very agreeable. The soil is the best in all these districts: fruits, vines, olives, and sesamum, succeed here extremely well; but cultivation is wanting. They reckon about 600 men in this village capable of bearing arms upon occasion; and this often occurs, sometimes to resist the Pacha, sometimes to make war with the adjoining villages, and sometimes in consequence of intestine dissensions. Of these 600 men, about 100 are Latin Christians, who have a vicar dependent on the great convent of Jerusalem. Formerly their whole trade consisted in the manufacture of beads, but the reverend fathers, not being able to find a sale for all they could furnish, have resumed the cultivation of their lands. They make a white wine, which justifies the former celebrity of the wines of Judea, but it has the bad property of being very heady. The necessity of uniting for their common de-

fence prevails over their religious differences, and makes the Christians live here in tolerable harmony with the Mahometans, their fellow-citizens. Both are of the party *Yamani*, which, in opposition to that called *Kaisi*, divides all Palestine into two factions, perpetually at variance. The courage of these peasants, which has been frequently tried, has rendered them formidable through all that country." See Volney's *Travels*, vol. ii. p. 322. Maundrell's *Journey to Aleppo*, p. 132. Browne's *Travels in Africa*, p. 363. *Ant. Univ. Hist.* vol. ii. p. 477. Calmet's *Dict.* (A. F.)

BETHUNE. See SULLY.

BETHUNE, a town of France, in the department of the Pas de Calais, situated on a rock in the river Bietre. The castle is irregular, and, together with the city, forms a triangular figure. Population 5000. (j)

BETULA, a genus of plants of the class Monœcia, and order Tetandria. See BOTANY. (w)

BEVELAND. See ZEALAND.

BEVERIDGE, WILLIAM, was born at Barrow in Leicestershire, A. D. 1638, and was educated at St John's College, Cambridge, where he distinguished himself by his uncommon attainments in the learned languages, by his early piety and seriousness of mind, and by his exemplary sobriety and integrity of life. He took the degree of master of arts in 1660; and was ordained priest the following year. He was soon after collated to the vicarage of Yealing in Middlesex; and in 1672, was chosen rector of St Peter's, Cornhill, London. He was successively promoted to the prebend of Chiswick, the archdeaconry of Colchester, the prebend of Canterbury, and the bishopric of St Asaph. He enjoyed the episcopal dignity little more than three years; and died in the 71st year of his age, A. D. 1708. Bishop Beveridge published, during his life, the following works: *De Linguarum Orientalium, &c. prestantia et usu*, 1658. *Institutionum Chronologicarum libro duo*, &c. 1669. *Συνοδικον sive pandectæ Canonum*, S. S. &c. 1672. *Codex Canonum*, &c. vindicatus, 1679. The Church Catechism explained, &c. 1704. And after his death were published; *Private Thoughts upon Religion*, &c. *Private Thoughts upon a Christian Life*, &c. The great Advantage and Necessity of Public Prayer and Communion, &c. One hundred and fifty Sermons and Discourses, &c. 12 vols. 8vo. *Thesaurus Theologicus*, or a Complete System of Divinity, &c. 4 vols. 8vo. A Defence of the Book of Psalms, collected into English Metre, by Thomas Sternhold, &c. Exposition of the Thirty-nine Articles. In 1711, there was published in London, a very severe attack upon the bishop's works, in a pamphlet entitled, *A Short View of Dr. Beveridge's Writings*, &c. in which he is charged with a strong tendency to jingle and quibbling in his style, with inaccurate reasoning, and with defective arrangement in many of his discourses; but the writer seems to have been chiefly influenced by a dislike of his Calvinistic sentiments. Whatever diversity of opinion may be entertained on these points, it cannot easily be denied, that Bishop Beveridge was possessed of very extensive learning, and a great variety of useful knowledge; that he was remarkable for his intimate acquaintance with sacred scripture, a readiness in producing, and a felicity in explaining, the most suitable passages on all occasions; that his writings are distinguished by a truly primitive and apostolical character, and by a rare unity of

gravity and simplicity; that he was remarkably diligent, regular, and earnest in every part of his pastoral duties; and that, the higher his preferments, the more watchful and exemplary he became in the whole of his conduct, the more laborious and zealous in advancing the honour and interests of religion. He was an able and active opposer of the principles of popery, and one of the framers of the English liturgy. He bequeathed the greater part of his property to charitable purposes in his native village; and to the societies for propagating the gospel, and for promoting Christian knowledge. See *Biog. Britannica*. *Biog. Dictionary*. Noble's *Continuation of Granger*, vol. ii. *Guardian*, vol. i. N^o 74. Felton's *Dissertation on reading the Classics*, &c. p. 199. Nelson's *Life of Bp. Bull*, p. 75. (g)

BEVERLEY, a well built town of England, in the East Riding of Yorkshire, situated near the river Hull. The minster of Beverley is a large and handsome edifice. The market place contains about four acres, and is decorated with a beautiful cross, supported with eight free-stone pillars, which was erected by some of the members sent by the town to Parliament. Beverley carries on a considerable trade in malt, oat-meal, and the tanning of leather. In the common connected with the borough, is a mineral spring, which has proved of some service in diseases of the skin. Number of houses 1228. Population 5401, of whom 521 were returned as employed in trade and manufactures. (j)

BEVIEUX, a village of Swisserland, celebrated for the salt springs in an adjacent mountain. A gallery about six feet high and four broad, is cut into the mountain, through a black rock veined with gypsum. The springs rise in a solid rock, and the richest of them yields 28 per cent. of salt, while the poorest gives only $\frac{1}{2}$ per cent. Only a few cubes of rock salt have been found in the mountain, though it abounds with saline particles. Several sulphureous springs, containing a little salt, and flaming by the application of a lighted candle, occur near the salt springs. Rocks of white gypsum, with a mixture of bluish clay, are also found in their neighbourhood, as in the salt mines of Northwich in Cheshire. "After travelling in this subterraneous passage," says Mr Coxe, "near three quarters of a mile. I observed a great wheel of 35 feet diameter, which raises the brine from the depth of about 70 feet. From this place is a shaft 300 feet high, which is cut through the mountain to the surface, for the purpose of introducing fresh air. I noticed, too, reservoirs, hollowed in the solid rock for holding the brine; one was 160 feet square, and 9 in depth. Since my first expedition to these pits in 1776, the workmen had pierced the rock 25 feet deeper, and cut a gallery 100 feet in length. They had also begun to form a third reservoir, to contain 5500 cubic feet, which was nearly half finished. The brine deposited in these reservoirs, is conveyed by means of 2000 pipes, about a league to Bevioux, where the salt is extracted. The brine pits near Aigle contain only from 2 to $\frac{1}{2}$ per cent., and yield annually about a third as much as those of Bevioux, or about 5000 quintals. The salt is much whiter and heavier than that of Bevioux, and consequently bears a higher price. These, which are the only salt-works in Swisserland, scarcely yield a net yearly profit of more than 3000*l.* and furnish only one-twelfth of the annual consumption of the cantons. The remainder is procured chiefly from France, which by treaty provides the Swiss States with this commodity at a moderate price. Indeed, so high is the tax

upon salt in that kingdom, that even the French salt is sold two-thirds cheaper in Switzerland than in many parts of France. The ordinary price of common salt throughout the canton, is three halfpence per pound." See Cox's *Travels in Switzerland*, vol. ii. p. 104. Letter xliii. Bevicux is three miles south of AIGLE. (v)

BEWCASTLE, a village of England, in the county of Cumberland, situated on the river Line, remarkable for some Roman antiquities, and a famous obelisk decorated with figures in bas-relief, and containing a Roman inscription. A particular account of these ancient relics will be found in Hutchinson's *History of Cumberland*. (j)

BEWDLY, or BEAULIEU, a town of England, in Worcestershire, finely situated on a declivity on the banks of the river Severn, over which there is a bridge erected by Edward IV. A curious hermitage, with a chapel and several apartments, is hollowed out of the beautiful rock at the edge of the water. The manufactures of Bewdly chiefly consist in tanning, malting, and horn-work, and it carries on a considerable trade in malt, leather, salt, and iron ware, by means of the Severn, which is here navigable. Number of houses 787. Population 3671, of whom 939 were returned as employed in trade and manufacture. See Nash's *History and Antiquities of Worcestershire*. (j)

BEY, or BEGH, the name of an inferior officer in the Turkish empire, who governs one of the seven sandjacks into which each province of that empire is divided. See TUNIS, TURKEY, and Sonnini's *Travels*, p. 424. : Browne's *Travels in Africa*, p. 47. ; and Volney's *Travels*, vol. i. (j)

BEYKANEER, a province in the north-east of Hindostan, bounded on the south by Joudpore ; on the south-west by Jesselmere ; on the west by the Desert ; on the north by the country of the Batnians ; on the east by Hurriana ; and on the south-east by Jypore. Its width from east to west is about 80 coss, and its length, from north to south, 120 coss. The soil of this province is very unproductive, excepting near some of the villages at its eastern boundary ; but even there the labour of the husbandman is scarcely repaid. Hence the inhabitants are obliged to import from their neighbours, rice, corn, sugar, salt, opium, &c. In consequence of the rapid absorption of the rain in the sandy soil, the inhabitants are obliged to dig pits for the preservation of the water, which are generally 100 and 200 feet deep, and sometimes even 300. Every family has a cistern of this kind ; and sometimes the drought is so great, that whole families are compelled to emigrate. Soorut-Sing, the rajah of Beykaneer, has absolute power over the lives and properties of his subjects. By dissipating the treasures of his ancestors, he has oppressed his subjects with the most cruel exactions ; and is obliged to maintain his power by an army of 4800 infantry, 3200 cavalry, and 50 pieces of artillery. Though he has several Europeans in his service, his invasions of the Batnians and of Cluroo have generally been unsuccessful. The revenues of this province are about three lacs of rupees, though this sum has been sometimes doubled by imposts upon the merchandise which pass through the country. This rapacity, however, has forced the merchants to carry their goods by a different route. (H)

BEYKANEER, the capital of the province of Beykaneer, is a large and well built town, surrounded by a wall. About an English mile to the south-east of the town is situated the fort, which is the residence of the

rajah. It is a strong place, encircled with a wide and deep ditch. This place, however, derives its chief security from the *disette* of water in the neighbourhood. (H)

BEZA, THEODORE, a celebrated French reformer, was born of noble parents, at Vezelai, in Burgundy, on the 24th of June 1519. His uncle, who was counsellor of the parliament of Paris, took the charge of him during his infancy, and sent him to Orleans in 1528, to be instructed by Melchior Wolmar, under whom he continued about seven years, and made rapid progress in the various branches of polite literature. When Wolmar returned to Germany, his native country, in 1535, Beza was sent to study law at Orleans ; but he preferred the cultivation of classical learning, and employed a considerable portion of his time in the composition of verses. In 1539, he took his licentiate's degree, and went to Paris, where he was provided with two good benefices. He succeeded also to the benefices of his elder brother ; and his uncle, the Abbe de Froimond, had promised to resign his abbey to him, which was worth 15,000 livres a-year. In such opulent circumstances, Beza was strongly tempted to continue in the Catholic faith, though he declares, that he never gave up the resolution of abandoning it. Having been afflicted with a dangerous illness, he renewed his vow to profess the reformed religion ; and as soon as he had recovered sufficient strength, he fled to Geneva, along with a lady whom he had formerly promised to marry, and arrived in that city on the 24th October 1548. In the following year he accepted of the Greek professorship at Lausanne, where he continued nine years fulfilling the duties of his office, and occasionally reading lectures on the New Testament to several French refugees who resided in that town. In consequence of an assembly of 400 Protestants having been surprised and taken prisoners at Paris in 1557, Beza, along with Farellus and John Budeus, went as a deputy to some of the German princes, to beg their intercession with the court of France in behalf of the persecuted Protestants ; but he returned to Lausanne, without having completely gained the object of his mission. Desirous to devote himself wholly to divinity, and actuated by other motives which Beza himself declines to mention, he left Lausanne, and returned to Geneva, where he became the colleague of Calvin, both in the church and the university, and co-operated with that zealous reformer in promoting the great objects of the Reformation. At the earnest solicitation of some of the leading men in the kingdom, Beza was invited to Nerac, to convert the king of Navarre ; and, at the desire of this prince, he assisted at the conference of Poissy. His speech before this assembly was received with the utmost attention, till he declared, "that the body of Jesus Christ was as distant from the bread and wine, as the highest heaven is from the earth." At this sentiment the prelates murmured, and made a noise : Some of them exclaimed, *Blasphemavit !* others left the assembly ; and the Cardinal de Tournon requested the king, either to silence Beza, or to permit him and the other ecclesiastics to withdraw. The king however refused to interfere, and Beza concluded his able and intrepid harangue.

At the desire of Katherine de Medicis, Beza remained in France. After the Massacre of Vassy, on the 1st of March 1562, he was deputed to complain of this violence to the king ; and, during the civil war which ensued, he attached himself to the Prince of Conde, and

was present as a clergyman at the battle of Dreux. After the confinement of the Prince of Conde, Beza lived with admiral de Coligni, till his return to Geneva, after the peace of 1563. In 1568, he went to Vezelai, to settle his father's affairs, and to attempt the conversion of his sister, who had retired to a convent. In 1571, he again went to France, to assist at the synod of Rochelle, where he was elected moderator; and, in 1572, he was present at the synod of Nismes, where he opposed the introduction of a new discipline, proposed by the party of John Morel. In 1574, the Prince of Conde invited him to Strasbourg, to go on a mission to Prince John Casimir, administrator of the palatinate. In 1586, he was engaged in the conferences of Montbeliard, and in those of Bern in 1588. Having lost his wife, he married, during the same year, a widow, who survived him. In consequence of a report raised by the Jesuits, that Beza was dead, and had professed on his deathbed the Catholic religion, he wrote verses full of vigour against that body; and in the year 1600, he wrote a *votiva gratulatio* to Henry IV. His health now began to decline, and he died on the 13th of October 1605, and was buried in the cloister of St Peter.

It is difficult to discover the true character of Beza amidst the gross calumnies of the Catholics, and the exaggerated encomiums of his own party. He has been accused of hypocrisy, infidelity, murder, and crimes that cannot even be named; but there is every reason to believe, that these charges were the malicious inventions of his theological opponents. It does not appear, however, from a careful examination of the life of Beza, that he was distinguished by that untainted purity and irreproachable conduct that we would wish to admire in the character of a reformer.

Beza was the author of numerous works in theology, of which his Latin translation of the New Testament is the principal. His *Juvenile Pieces* were published at Paris, in 1597, under the title of *Theod. Bezae Poemata Varia*. See Anton. Fayus *De Vita et Obitu Theod. Bezae*; and Bayle's *Dict.* (π)

BEZIERS, the *Biterre* of the ancients, a city of France, in the department of Herault, beautifully situated on a declivity near the junction of the great south canal and the river Orbe. The objects chiefly deserving of notice are—its cathedral; its college, founded in 1599; its academy of sciences and belles lettres; its ancient wall, flanked with old towers and bastions; and the remains of a Roman amphitheatre. Its principal manufactures are cloth, fustians, silk stuffs, brandy, and distilled spirit of wine. Beziers was once a populous and flourishing city; but in 1209, during the crusade against the Albigenses, no fewer than 50,000 of its inhabitants were put to the sword. Within sight of Beziers there are eight sluices of the superb canal already mentioned, which form a cascade 156 toises long, with a declivity of 11 toises. The soil around Beziers is the best in the department. Population 14,211. E. long. $3^{\circ} 12' 33''$, N. Lat. $43^{\circ} 20' 41''$. (q)

BEZOAR, the name of a calcareous concretion found in the stomach of a species of goat, or, according to others, in individuals of the antelope genus. It derives its name from the Persian *pazar*, a goat, or from the Persian *pazachar*, from *pa*, against, and *zachar*, a poison, the bezoar stone having long been regarded as an antidote against poison, and, in short, as an universal medicine. Dignified with such inestimable virtues, bezoar stones, when only an ounce in weight, have some-

times been sold in India for 100 livres; and their value increased with their magnitude, according to a very rapid progression. In the centre of the oriental bezoar, which is composed of smooth concentric lamina, of an olive colour, is generally found, in a nucleus, pieces of straw or hay, small stones, hard seeds, &c. but most commonly the pod of a particular kind of fruit.

The occidental bezoar is more rough in its surface than the oriental, and has sometimes been found in the camel tribe. The specific gravity of the oriental bezoar is 1.666, and that of the occidental 2.233. (u)

BEZOUT, STEPHEN, a celebrated French mathematician, was born at Nemours, in the department of the Seine and Marne, on the 19th of March 1730. His attention was accidentally directed to the study of mathematics, by some elementary works on geometry which fell into his hands, and by the perusal of Fontenelle's *Lives of the Academicians*, from which he saw, that tranquillity and glory were the high rewards of a successful study of the sciences. The youthful ardour which was thus inspired, was at first checked by the opposition of his father; but every restraint was found to be unavailing, and Bezout was at length permitted to give his undivided attention to the study of geometry.

Before he had reached his 28th year, he presented to the Academy of Sciences two memoirs on the integral calculus, in consequence of which he was appointed adjunct mechanic on the 8th of April 1758. In the first of these memoirs he determined the form of similar functions, in which the variable quantities are connected by an equation, and which, multiplied by constant factors, and added together, become algebraically rectifiable; and in the second memoir he gave the general equation of rectifiable curves. By these memoirs the fame of Bezout was so much extended, that in the year 1763, the Duke de Choiseul appointed him examiner to the marine, and requested him to draw up a course of mathematics for the use of those destined for the navy. In 1768, he was chosen associate to the Academy of Sciences, and member of the Marine Academy; and upon the death of Camus, he succeeded him as examiner to the royal corps of artillery. In 1779, he published his *General Theory of Equations*, a work on which he had laboured with unremitting assiduity since the year 1762. During these researches, Bezout obtained a solution of a particular class of equations of all degrees. This method, which was entirely new, was general for equations of the third and fourth order, and became particular in equations of the fifth degree. By means of several new theorems on the calculus of finite differences, he discovered a general method for the extermination of unknown quantities, by which he was enabled to avoid the tedious and complicated calculations which would otherwise have been necessary, and to determine beforehand the form and degree of the final equation. His *Course of Mathematics for the Marine* was completed in 6 vols 8vo in 1764; and in 1770, he finished his *Course for the Corps of Artillery*, in 4 vols 8vo. These elementary works have passed through several editions, and have been used in a great number of seminaries as peculiarly adapted for initiating the young in the elements of mathematics. The private studies of Bezout were greatly interrupted by the nature of his public duties. The examination of the marine and artillery schools, and the frequent journies which he was on this account compelled to take, occupied much of his time; but harassing

as these duties must have been to a man of genius, they were discharged by Bezout with the most unremitting assiduity, and with the utmost tenderness and affection for his pupils. During an examination at Toulon, two of his pupils were prevented by the small-pox from attending it publicly. In consequence of this misfortune, their progress would have been retarded a whole year, had not Bezout, at the risk of catching the infection, examined them in their own apartments. Though the attention of this able writer was chiefly directed to geometry, he found leisure to study mineralogy and several branches of physics. He was the first who gave any account of the crystallized stones of Fontainebleau, of which more full and recent accounts have been given by M. de Lasome.

Bezout married when he was very young, and was the father of a family whom he rendered happy by his domestic virtues. Fond of retirement and study, his manners were reserved and cold, and his conversation marked by no uncommon qualities; but the warmth and sensibility of his heart were apparent to those who knew him well, and the natural sagacity and extensive knowledge which he possessed were displayed only to his particular friends. The regular and abstemious life which he led, held out to him the prospect of a long life; but the fatigues of his public duties, the severity of his private studies, and the bitterness of personal chagrins, triumphed over the natural strength of his constitution. A malignant fever, to which he fell a victim on the 27th September 1783, carried him off from the cares and labours by which it was engendered.

Besides the works of Bezout which we have already mentioned, he published several mathematical papers among the Memoirs of the Academy for 1758 and 1762. He also wrote a paper on the Integration of Differentials, in the *Memoires des Savans Etrangers*, vol. iii.; and another containing Experiments on Cold, in the Memoirs of the Academy for 1770. (β)

BIAFARAS, a nation of Africans inhabiting a district lying between 11° and 12° of N. Lat. and from 13° to 14° 30' W. Long. bounded on the south by the Rio Grande. Very little is known either of themselves or the limits of their country; but it appears that they formerly possessed more extensive territories to the south west, and in particular the island Bulama, which we unsuccessfully attempted to colonize. From these they were expelled by their warlike neighbours towards the end of the seventeenth century, when they retired further up the Rio Grande merely for the enjoyment of peace. In stature the Biafaras are rather tall, but of a slender feminine figure, unlike the strong and robust natives of other parts of Africa, and are also unlike them from being a mild, peaceable, and inoffensive race, whence they are held in great contempt by the Bijugas, another nation with whom they are constantly at war. They are of a lively disposition, have a wonderful propensity to talking, and seem to be endowed with a ready apprehension of things within the limits of their understanding. Captain Beaver, to whom they paid frequent visits, relates, that one evening, having several Biafaras in his room, he shewed them prints by candle light, but it was some time before they could comprehend that they were intended to represent living or inanimate objects in nature; and probably they would not have done so, had he not casually turned to a view of Sierra Leone, where an elephant and a monkey were introduced, which highly delighted them. Then resorting to the plates of Lavater's Physi-

ognomy, he at length came to that of the *angry wicked man*. The instant the Biafaras beheld it, they all screamed and fled out of the room.

No calculation can be formed of the numbers composing the Biafara nation. It is certain, that they are governed by different chiefs, and that they have several towns, among which are named Goli, Gonfode, Ghinala, and Bulola. According to M. Durand, the first contains 4000 inhabitants; a fact we are much inclined to doubt, as well as other parts of his account of the western coast of Africa, so far at least as respects his personal acquaintance with them. Ghinala, or Inala, is thirty miles from the mouth of the Rio Grande, and Bulola seventy. There were two kings or chiefs in the district of Ghinala while Captain Beaver was on Bulama, with whom he made a treaty for the island, and likewise for a large portion of their continent. Bulola was governed by a woman. The Biafaras are said to trade to some extent with the Portuguese. They brought ivory, cloths, and poultry to the English settlement, and were extremely desirous that Captain Beaver should establish himself among them. See Beaver's *African Memoranda*. Lajaille, *Voyage au Senegal, par Labarthe*. Durand's *Voyage to Senegal*. (c)

BIANCHINI, or **BLANCHINUS**, FRANCIS, a mathematician and astronomer, who is chiefly remarkable for the dispute between him and Cassini, respecting the diurnal rotation of Venus, of which we have already given a full account in the article **ASTRONOMY**, p. 585. Bianchini was born of a family of rank at Verona, on the 13th of December 1662, and was educated for the clerical profession. After obtaining the degree of doctor in divinity, he was appointed librarian to Cardinal Ottoboni, afterwards Pope Alexander VIII., and was subsequently promoted to two canonicies in Dainaso. His mathematical knowledge obtained him the situation of secretary to the congregation for the reform of the calendar; and, on this occasion, he published two dissertations, entitled, *De Calendario et Cyclo Cesaris, ac de canone Paschali Sancti Hippolyti Martyris*. In his work, *De Nummo et Gnomone Elementino*, he gives an account of his operations in tracing the meridian line in the church of the Chartreux, at Rome; in memory of which, Clement XI. ordered a medal to be struck. During eight years he was employed in continuing the meridian through the whole of Italy, and when engaged in this occupation, he was cut off by the dropsy, on the 2d of March 1729. Though Bianchini has not left behind him any lasting monument of his talents, yet such was the reputation of his learning, that he was admitted a foreign associate in the Academy of Sciences at Paris, in 1706; created one of the nobility of Rome; and the inhabitants of his native city erected a bust to his memory in the cathedral of Verona. Besides the works already mentioned, he published, in 1726, a treatise on the discovery of a subterraneous building, entitled, *Camera ed Inscrizioni Sepolcrali di Libertii Servi, ed ufficiali della casa di Augusto*, &c.; in 1728, his *Hesperii et Phosphori Nova Phenomena*, &c.; in 1680, his *Dialogo Físico Astronomico contro il sistema Copernicano*, 4to.; in 1684, his *Cometes anno 1684 mensibus Junio et Julio, Romæ Observatus*; in 1684 his *Nova Methodus Cassiniana Observandi parallaxes et distantias Planetarum a terra*; in 1703, his *Solutio Problematis Paschalis*, &c. and, in 1697, appeared the first volume of a great work on universal history, entitled, *La Istoria Universale provata con monumenti, et figurata con Simboli de gli Antichi*, &c.; and an edition of *Anastasius's Lives of the Popes*, with dissertations and notes.

A posthumous work, with plates, entitled *Francisci Bianchini Veronensis utriusque Signaturæ referendarii, et prelati domestici, de tribus generibus instrumentorum musica veterum organicæ dissertatio*, was published at Rome in 1742, in 4to. The various papers which he wrote will be found in the *Memoirs of the Academy* for the years 1702, 1703, 1704, 1706, 1707, 1708, 1713, and 1718. In 1737, Eustachio Manfredi published the observations of Bianchini, under the title of *Francisci Bianchini observationes selectæ Astronomicæ, et Geographicæ Romæ et alibi per Italiam habitæ, ex ejus autographis excerptæ, una cum geographicâ meridiani Tabulâ, a mari supero ad inferum, ex iisdem observationibus collecta et concinnata*; Veronæ, fol. Among the observations of Bianchini, those upon Venus are very singular; and we are much at a loss whether to consider them as absolute fabrications, or as the result of optical illusions which he had not the sagacity to discover. The disadvantages attending the use of the long refracting telescopes were considerably, though not altogether, removed by the contrivance of Huygens, by which tubes were rendered unnecessary. In 1712, Bianchini brought to Paris a contrivance of his own for the same purpose, which was described in the memoirs of the academy for 1713. With long telescopes, to which this invention was adapted, he seems to have observed Venus with unremitting assiduity. He perceived, or thought he perceived, seven large spots towards the middle of her disc, which communicated with one another by four straits; and towards the extremities of her disc he observed other two spots, which had no communication with the former. He saw even promontories or projections of these dark regions into the lighter part of her disc. In imitation of Riccioli, he called those spots and promontories after eminent men, among whom were, the king of Portugal, Galileo, Cassini, Columbus, Vesputius, Magellan, and several Portuguese generals who had distinguished themselves by their conquests in the Indies. From the change of position in these spots, Bianchini concluded that Venus revolved about her axis in 24 days 8 hours. It is a very remarkable circumstance, that the admirable telescopes employed by Herschel and Schroeter have never yet been able to discover any of these spots perceived by Bianchini; and we are the more inclined to suspect some great source of error, as it is now proved, by the accurate observations of Cassini, Herschel, and Schroeter, that Venus revolves about her axis in a little less than 24 hours, instead of 24 days, as Bianchini determined. For farther information respecting the life of this author, see his Eloge in the *Hist. Acad. Par.* 1729; in the *Nouvelles Littéraires de Leipzig*, Jan. 1731; and in Fontenelle's *Eloge des Académiciens*, in the *Oeuvres de Fontenelle*, tom. vi. p. 213. See also La Lande's *Voyage d'Italie*, tom. iv. p. 311, edit. 1786. (o)

BIBERACH, an ancient city in the Confederation of the Rhine, belonging to Baden, situated in a valley traversed by the river Reiss. It was formerly a free and imperial city, under a government similar to that of Augsburg. The paper and the fustians manufactured in this place have been long celebrated. The cold bath of Jordan is very near the town. Population 6600. E. Long. 10° 2', N. Lat. 48° 4'. (j)

BIBLE. See **CHRISTIANITY**, **SCRIPTURES**, and **THEOLOGY**.

BIBLIOGRAPHY. (from βιβλος, a book, and γραφω, to write,) a name which has been recently employed by many continental writers to comprehend every thing

that relates to books; and as every branch of knowledge is contained in books, they have, by a strange process of reasoning, employed the word **BIBLIOGRAPHY** to denote a science which comprehends all the other sciences. M. Peignot has preferred the more general term of *Bibliology*, which he divides into seven different heads, viz.

1. **GLOSSOLOGY**, or the knowledge of languages.
2. **DIPLOMACY**, or the knowledge of writings.
3. **BIBLIOPEDIA**, or the composition of books.
4. **TYPOGRAPHY**, or the knowledge of printing.
5. **BIBLIOPOLY**, or the knowledge of bookselling.
6. **BIBLIOGRAPHY**, or the knowledge of books.
7. **UNIVERSAL LITERARY HISTORY**.

These various heads are branched out into innumerable subdivisions, embracing every subject to which the human mind has ever been directed. To have accomplished such a task, with even tolerable success, would have required the universal powers of a Bacon or a D'Alembert; but when it has been executed by one who does not pretend to a knowledge of the sciences, our readers may well conjecture what a mass of bad arrangement has been heaped together under the sacred and dignified name of a science.

In arranging the books of a library, it is certainly necessary to follow some general division of human knowledge, but it would be neither proper nor convenient to adopt that scientific classification which results from a perfect acquaintance with the sciences, and the various relations by which they are connected. This subject will naturally come under our consideration in the article **LIBRARY**; and under the word **Books**, we shall lay before our readers that information which some of them might have expected to find under the present article. (w)

BIDEFORD, a market and sea-port town of England, in Devonshire. It is situated chiefly on the slope of an eminence on the banks of the river Towridge, a little above its junction with the Taw, which falls into Barnstaple bay. The streets are clean, and the houses well built, though they are chiefly constructed of timber, brick, and mud. The quay is conveniently situated near the centre of the town, and at high tides will admit a vessel of 500 tons. The river is crossed by a stone bridge of 24 irregular arches, built about the middle of the 14th century. Biddeford carried on a great commerce with Newfoundland about the middle of the last century. It still enjoys a considerable trade in the importation of fish from Newfoundland, and the salt with which the herrings are cured is brought from Liverpool and Warrington; but the vessels belonging to the port, which amount to nearly 100, varying from 20 to 250 tons, are principally employed in the carriage of coal and timber, and in the exportation of oak and bark to Scotland and Ireland. Large quantities of earthen ware are manufactured here and sent to Wales. Number of houses 582. Population 2987, of whom 325 were returned as employed in trade and manufactures. See Watkin's *History of Biddeford*, and Maton's *Tour through the Western Counties*. (j)

BIDENS, a genus of plants of the class Syngenesia, and order Polygamia Æqualis. See **BOTANY**. (w)

BIENNE, a town of France in the department of the Haut Rhine, and formerly the capital of a district of the same name in Switzerland. It is situated at the foot of Mount Jura, near the northern extremity of the lake of Bienna. The town is built in the ancient style; and

is chiefly remarkable for its tanneries, its manufacture of printed cloths, and a fine inexhaustible source of water, which supplies the pipes of 60 public fountains. A large common between the town and the lake, belonging to the burghers, is laid out in small kitchen gardens.

The lake of Biemme, which is of an oval form, is nine miles long and four broad. Its margin is decorated with villages and castles, and affords many beautiful and picturesque views.

The lake of Biemme is celebrated by the island of St Peter, which was the temporary residence of Rousseau when he withdrew from Moitier. The island of St Peter is about two miles in circumference; on its southern side it slopes gently to the lake; but in other directions it is steep and rocky. Large oak, beech, and chestnut trees, decorate its gently undulating surface, which is traversed by agreeable walks, terminating in a circular pavilion in the centre of the island. Parties from Biemme, Nidau, and the surrounding country, resort in the time of the vintage to this enchanting spot, which has been rendered classical by the short residence of Rousseau. This singular character lived in the farm house, the only one in the island, which belonged to the steward of the general hospital at Berne, to whom he paid 40 shillings per month for his board and lodgings. He remained here only two months, and the room that he occupied, from which there is a fine view of the glaciers, is shown to strangers as an object of curiosity. A full account of the ancient district of Biemme, which is now included in the department of the Higher Rhine and a more particular account of the lake, may be seen in Cox's *Travels in Switzerland*, vol. i. p. 210, 211, &c. and vol. ii. p. 152. See also *Dict. de la Suisse*, (π)

BIEQUAL THIRD, in music, is a name given by earl Stanhope, in his *Principles of the Science of Tuning*, to an interval, two of which added to a major third make up an octave, consequently two of them is equal to a minor sixth; and its ratio, in his lordship's monochord system, is $\sqrt[10]{\frac{10}{4}} = 207\frac{1}{2}\Sigma + 4f + 18m$ (see Plate XXX.) this exceeds the perfect IIIrd by $10\frac{1}{2}\Sigma + m$, $= \frac{2}{2}\epsilon$ nearly: the logarithm of this biequal third is .8979400,0867; and it may be worthy of remark, that it exceeds a minor third by $L + \frac{1}{2}\Sigma$, and is $\frac{1}{2}\Sigma$ larger than a deficient flat fourth.

In the *Equal-beating* system of his lordship, that is, where his two successive thirds, composing a true minor sixth, are made to *beat equally quick*, two other biequal thirds arise, having finite ratios, the largest of which is $\frac{15}{19}$, whose logarithm is .8973376,5811; and the smallest has a ratio of $\frac{19}{23}$, whose logarithm is .8985423,5924; whence it appears, that one of these is larger and the other smaller than the monochord biequal third, first described; circumstances of which the noble earl seems not to have been aware, any more than that two of such successive biequal thirds as produce *no beating between the two beatings*, (which his lordship last proposed, as the mode of tuning his *equal beating* intervals, *Phil. Mag.* xxviii. p. 151.) are *not equal* to each other in any case whatever. The theorems whence the above ratios were deduced, and whence those of his lordship's triequal thirds and others may deduced, will be given under the article EQUAL-BEATING *Intervals*, which see. (g)

BIENNIAL PLANTS. See GARDENING.

BIGAMY. See POLYGAMY.

BIGGLESWADE, a town of England, in the county of Bedford, situated in a line valley on the banks of the Ivel, which is here navigable. It has one of the largest markets in England for barley, pease, and oats, and there is also here a small manufactory of thread lace and edgings. Several old houses were thrown down in this town by an earthquake, which was felt on the 25th of February 1792. Number of houses in 1801, 301. Population 1650, of whom 258 were returned as employed in trade and manufactures. See *Beauties of England and Wales*, vol. i. (j)

BIGNONIA, a genus of plants of the class Didymia, and order Angiosperma. See BOTANY. (w)

BIGORRE, the name of a district in Guyenne, one of the former provinces of France, but now included in the department of the Upper Pyrenees. See PYRENEES, UPPER. (j)

BIJORE, the name of a mountainous province of Hindostan. Its history is devoid of interest, and we have no statistical information respecting it that is worth communicating. See Rennel's *Memoir*, p. 159. (w)

BIJUGA, or BISSAGOS ISLANDS. The western coast of Africa, between the River Gambia and the Rio Grande, consists of a chain of low fertile islands, separated from each other, and also from the continent, by narrow navigable canals, in consequence of the sea encircling them. To the south-west of these islands is an archipelago, consisting of 18 or twenty islands, stretching above 40 leagues from north-west to south-east, called the Bijuga Islands, bounded on the one side by immense shoals, which, being little known, are frequently fatal to navigators; and on the inside by a channel, about five leagues in width, called the Bijuga channel. Neither the exact limits of these islands, however, nor their number, are definitely ascertained; but thirteen are said to be inhabited. We are disposed to consider them a separate and distinct groupe from those on the north-east side of the channel, though other geographers rank the latter along with them.

The Bijuga channel is deep, and is fit for the navigation of the largest vessels; it stretches nearly 50 leagues in length, and terminates with the island Bulama. The islands gradually rise from the shore towards the interior; none are above six leagues in length, nor any where appear to be above 40 feet higher than the level of the sea. Some navigators consider them of volcanic origin; others think that they are alluvial, and that they have been formed, in the course of time, by the deposit of the Rio Grande and the neighbouring streams, on the extensive sand banks which serve for their base. The Bijuga islands are rich and fertile, abounding in all the necessaries of life, beautiful, and well-wooded, whence they have long been recommended as suitable for European settlements. Warang, also called Formosa, Cazegoot, Canabac, Bulama, Carashe, and Suoga, which was peopled but lately, are those of principal note. The three immediately north-west of the channel, Jatte, Bassis, and Bissao, have usually been added to their number, though, as we have said, we think they should be separated from them. See BISSAO.

The people inhabiting the Bijuga islands are said to be originally Papels, a tribe still dwelling on the continent: they are above the middle size, muscular, bony, well proportioned, and have the appearance of great strength and activity. Their noses are flatter, and their

lips thinner, than those of the neighbouring tribes; their teeth, which they sometimes file to a sharp point like a saw, are good; and their hair is woolly. They cut their hair into many fantastic forms, and always dress it with red ochre and palm oil. They wear little clothing; a scanty girdle, and, in the colder season, a goat's skin thrown over the shoulders of the men, being their only covering: That of the women is equally simple, consisting of a girdle, six inches deep, of the shred of the palm leaves, which forms a thick fringe.

The Bijugas are a brave and warlike race; they are never at peace with the surrounding nations; and their chiefs, being endowed with uncommon intrepidity, are always to be dreaded. Captain Beaver describes one of their kings, with whom he had intercourse while on the island of Bulama. "Bellchore is the dread of the neighbouring people, and is reckoned the greatest warrior that the Bijuga nation ever produced. He still boasts of having set fire to the town of Bissao, notwithstanding its strong fort and numerous garrison; and to others he will probably boast of his triumph over us at the western point of Bulama. He is old, but upright and active, and stands full six feet high; his large black eyes, the fire of which seventy rains have not yet extinguished, are the most penetrating I ever beheld; his nose is large and projecting; his teeth regular and white; his limbs are well proportioned; his understanding is clear and acute; and in body and mind he stands pre-eminent among his countrymen. But his courage, his policy, his restless activity, his daring enterprises, and his love of war, which have rendered him the admiration of his own countrymen, have procured him, at the same time, the hatred and detestation of all those nations that lie within the reach of his lawless expeditions." Only a few days of the year are devoted by the Bijugas to their rude agriculture, in preparing the ground for rice; all the rest are occupied in war and hunting. Their arms are a long buccaneer gun, a spear, and a solingen sword about four feet in length, and literally as sharp as a razor; while in the left hand is carried a round convex shield, formed of withies interlaced, covered with the hide of a buffalo. The Bijugas perfectly understand the use of arms, and pride themselves in keeping them in the most perfect order. Captain Beaver relates, that their aim is so sure that they seldom miss their object, and that he had seen a spear, from the distance of twenty yards, strike a reed about ten inches long, and as small as a tobacco pipe; he likewise witnessed their extreme expertness at the broad sword. In war, after discharging their guns kneeling, and throwing them down, they cast their spears, and then have recourse to the sword. They approach in a squatting posture to the attack, while the shield nearly covers the whole body. Its convex form and strength are so well adapted for turning aside the shot of an enemy, that a musket ball will not pierce it. In 1696, the Portuguese took 300 Bijugas into their service, to aid an expedition against the Balantes, another tribe of Africans; but not anticipating the rainy season about to commence, their arms were rendered un-serviceable, and they were defeated with great loss. Their war canoes are of considerable size; fortunately for their less enterprising neighbours, they do not understand the use of sails, which is more surprising, as the vessels visiting their islands are provided with them.

The Bijugas, in common with most African nations, are cruel and treacherous, always ready to seize advan-

tages, and to overpower strangers. Those who have intercourse with them cannot be too much on their guard; whence ships repairing to the Bijuga islands, for the purposes of traffic, never allow more than the crew of a single boat to come on board, and even then the guns are primed and matches lighted. About 30 years ago, the crew of a French vessel, wrecked on the island of Yoko, were all massacred or led into captivity. The inhabitants of another island likewise endeavoured to seize M. Delajaille, when surveying the coast, as Labarthe informs us, and mortally wounded one of his companions. More recently they treacherously cut off some of captain Beaver's people, and would have effected his own destruction, had not his personal intrepidity, and a fortunate concurrence of circumstances, oftener than once prevented it. It has been asserted, that suicide is common among the Bijugas, and that the smallest chagrin will prompt them to leap into the sea, or terminate their existence with a dagger.

All the Bijugas are idolaters; they offer propitiatory sacrifices, and put implicit faith in divination. If they form a treaty with a stranger, or are about to undertake a warlike expedition, they sacrifice a cock, from inspecting the gizzard of which conclusions are drawn of good or evil omens. M. Brue, the French governor-general of Senegal, having anchored off the isle of Cazegoot, was visited by a near relative of the king, with whom he carried on a conversation, and supplied him with brandy, a liquor which these people will make every sacrifice to obtain. Meantime a canoe from the island arrived, and one of the natives came on board, holding a cock in his left hand, and a knife in his right. After kneeling before M. Brue, he arose and turned to the east; then cutting the animal's throat, he sprinkled a few drops of blood at M. Brue's feet, and afterwards performed the same ceremony at the masts and pump, which being finished, he presented the cock to the French commander. When M. Brue inquired into the meaning of the ceremony, the native told him, that the wise men of his country viewed the whites as the gods of the sea; and that the mast was a divinity which made the vessel walk, while the pump was a miracle raising the water up, whose nature it was to fall down. The Bijugas likewise firmly credit the efficacy of gris-gris, or charms, which consist of certain sentences of the Koran written on paper by the Mandingo priests: They are neatly sowed up in cloth, or leather, and attached to different parts of the body. A lucrative traffic is carried on in these gris-gris, which the fabricators will assert render whoever wears them invulnerable; and should any one accidentally escape an impending evil, the priest preparing the charm is esteemed far superior to any of his fraternity.

A traffic is carried on in the Bijuga archipelago, chiefly by small vessels from the Portuguese settlement of Bissao, and the English to the southward, for slaves and hides. The slaves being prone to revolt, and commit acts of desperation, commanders of ships are obliged to take more than usual precaution in securing them; for, on the slightest neglect, the slaves will murder them, seize the vessel, and run her ashore. M. Delajaille gives a list of all the articles suitable for the Bijuga islanders.

It has been so peculiarly the interest of the Portuguese to repel all strangers from that part of the African shores, that other nations are very imperfectly acquainted with the history of the native tribes. In 1687, while a French-

man, named Dekafond, was trading with the Isle of Cazegoot, the natives stole some of his property: A favourable opportunity of retaliation immediately occurring, by the arrival of a French ship of war, he induced the commander to engage with him in pillaging the whole island. Accordingly 200 men were landed, who invested the town, and burnt the king in his hut; but, except ten or twelve, the whole population, consisting of 2000 or 3000 people, fled to the woods, and escaped their sanguinary invaders. The French, however, had the address afterwards to conciliate the natives, and carry on a friendly traffic with them. More lately, during the projected settlement of Bulama, Captain Beaver, in 1792, made an amicable treaty with two of the kings, from whom he purchased that island for a quantity of goods. See Beaver's *African Memoranda*. Durand's *Voyage to Senegal*. Delajaille, *Voyage au Senegal*. (c)

BILBAO, originally *Bilbao*, or the Good Ford, is a town of Spain, and the capital of Biscay Proper. It is pleasantly situated on the Bay of Biscay, at the mouth of the river Ausa, which is navigable for boats. Bilbao was built in 1300 by Diego Lopez de Haro. The houses are high and well built, with projecting roofs, which shelter the pavement below from the sun and rain. The streets are paved with small square stones, and are kept remarkably clean and cool, by means of several canals which convey the water from the river. In this town there is a naval academy, several docks for building merchant vessels, four parishes, three convents of nuns, one chapel, and two asylums. There is here a highly decorated promenade, called the Arenal, which stretches along the bank of the river, and is planted with oaks and lindens, and bordered with warehouses, gardens, and houses adorned with paintings. In time of peace, this port is frequented by vessels from England, France, Holland, Bremen, and Hamburg, which import the productions of their manufactures and colonies, and export the wool of Old Castile, the anchors of Guipuzcoa, some rigging, iron, and chesnuts. It generally imports about 160,000 quintals of salt fish, and 6000 barrels of train oil. There were formerly a number of tan-yards here, but of late they have considerably diminished. The air is extremely damp, though the town seems to be healthy. The town contains about 200 mercantile houses. Number of houses 1200. Population 15,000. See Laborde's *View of Spain*, vol. ii. p. 356; and Bourgoing's *Travels in Spain*, chap. i. (π)

BILE. See ANATOMY, CHEMISTRY, and PHYSIOLOGY.

BILEDULGERID, an appellation given to one of the divisions of Northern Africa; but which has been continually varying in the extent of its application. It was understood by the older geographers, to comprehend all the countries formerly known by the name of Numidia; and was described as including the southern part of Algiers, with the whole tract of land between that kingdom and Egypt. It has been confined by De Lisle to a province called Biledulgerid Proper, situated to the south of Tunis, but properly speaking, under the government of that state, from which it is separated by a ridge of high mountains. In several later maps, however, and especially by the modern Arabs, the name Biledulgerid is applied to the whole of that district which lies between the maritime states of Barbary and Sahara, or the desert; which extends from 10 degrees west to 15 east longitude; from 29 to 33 north latitude; and which comprehends Lower Susse, Dara or Drala, Taflet or Tafilet,

Sigilnessa, and Biledulgerid Proper. The word has been analysed by some authors into Bled-el-Jerid, "the land of dates;" by others, into Bled-el-Jeraad, "the land of locusts;" but Dr Shaw, who writes it Biat-el-Jeride, and Mr Jackson, who makes it Bled-el-Jerrède, unite in giving it the interpretation of "the dry country." The country, especially in the central regions, is sandy, barren and mountainous, and almost entirely destitute of rivers and fresh water springs. In the districts nearer to the Atlantic, water may generally be found by digging three or four feet below the surface, but it is of a brackish taste, and unwholesome quality. The climate is extremely hot and unhealthy; especially in the months of July, August, and September, when a suffocating wind, loaded with particles of sand, and extremely pernicious to the eyes, blows very tempestuously from the desert. In many parts of this extensive tract, very considerable ruins are to be found, from which it would seem to have been formerly better peopled, and more carefully cultivated; but now its principal and almost only produce is dates, which grow every where in the greatest variety and abundance; though, in some spots of the more western provinces, a little Indian corn, rice, wheat, and barley, are produced: In these also a very superior breed of goats are reared, which are in high repute among the inhabitants of Morocco. The natives of Biledulgerid are chiefly composed of wild Arabs, who come originally from Sahara, and who resemble the wandering tribes, already described under the article BARBARY. Those of them who border upon the northern states, are rather more civilized and stationary in their habitations, frequently engaging in agriculture and the mechanic arts; but the inhabitants of the interior are a set of miserable and murderous banditti: They are a meagre, swarthy race, with shrivelled complexions, and almost continually afflicted with ophthalmia. Their principal food is the fruit of the date tree, the indigestive effects of which they are accustomed to correct by the use of dried fish. They use also camels milk, and goats flesh; and, on account of the intolerable heat, their principal meal is always after sun-set. They are extremely liable to a most inveterate scurvy, which affects their gums, loosens their teeth, and sometimes spreads over their whole body. In other respects, they are said to be vigorous and healthy, living to a very advanced age, and seldom subject to sickness and disease. The small-pox, and even the plague, the great scourges of Barbary, are said to be unknown in Biledulgerid, though the countries are so contiguous, and the inhabitants have so much intercourse. The natives are chiefly employed in predatory excursions, in serving occasionally as mercenaries under the neighbouring states, and particularly in hunting the ostrich, which supplies them with various necessaries. The flesh is used as food, the fat as medicine, the claws as ornaments; the skin is made into pouches, and the feathers constitute their most valuable article of traffic. All these Arabs profess the religion of Mahomed; but have little knowledge of its tenets, or regard to its precepts; and mix with it an endless variety of Jewish ceremonies, and Pagan superstitions. See *Mod. Univ. Hist.* vol. xvii.; and Jackson's *Account of Morocco*. (q)

BILL. See EXCHANGE.

BILL. See PARLIAMENT.

BILLIARDS, from the French BILLARD, which comes from *bille*, a ball, is a game of skill, which was originally invented by the French, and is now much in practice among all civilized nations. The apparatus necessary

in this game is a billiard table, which is a rectangular table about 12 feet long, and six feet wide, placed in a horizontal position, and covered with green cloth, and surrounded with cushions, a cue, a mace, and ivory balls. At each of the angles, and in the middle of the two longest sides, is placed a hole, net, or pocket. The cue is a thick piece of wood several feet long, tapering gradually to a point about half an inch in diameter. It is held by the fore finger and thumb, and is laid over the left hand to strike the balls. The mace, which is chiefly used in this country, is a long straight rod of wood, with a head at one end, made either of bone or ivory. It is held by the small end, and the ivory ball is struck with the other. The object of the player is to make his adversary's ball roll into one of the holes, either by striking it directly by his own, or by making his own ball rebound from the sides of the table, and then strike his adversary's ball, so as to carry it into one of the holes. When a ball is thus put into one of the holes, it is called a hazard, which is reckoned for two in favour of the player.

In order to play billiards well, attention must at first be paid to the method of holding the mace; to the position in which the player should stand, and the manner of delivering the ball from the mace; but these are much more easily acquired by observation, or by the direction of a good player, than by written rules. A person who plays with his right hand must stand with his left foot foremost; and, on the contrary, he who is left-handed, must place his right foot foremost, by which he will stand more steady and firm.

There are various games at billiards; viz. the white winning game; the white losing game; red, or carambole winning game; the red losing game; the simple carambole game; the winning and losing carambole game; the bar-hole game; the bricole game; the caroline game; the choice of balls game; the commanding game; the cushion game; the doublet game; the four game; the hazards; the limited game; the one hole game; the Russian carambole; and the fortification billiards: an account of each of which we shall give from Hoyle.

Rules and Regulations to be observed at the White Winning Game, played with two White Balls.—The game scored from winning hazards is twelve in number when two persons play, and fifteen when four play.

1. String for the lead, and the choice of balls. 2. When a person strings for the lead, he should stand within the limits of the corner of the table, and must not place his ball beyond the stringing nails or spots; and the player who brings his ball nearest the cushion, at the upper or baulk end of the table, wins the lead. 3. After the first person has strung for the lead, if the adversary who follows should make his ball touch the other, he loses the lead. 4. If the player holes his own ball, either in stringing or leading, he loses the lead. 5. If the leader follows his ball with either mace or cue past the middle hole, it is no lead; and if his adversary chuses, he may make him lead again. 6. The striker who plays at the lead, must stand with both his feet within the limits of the corner of the table, and must not place his ball beyond the stringing nails or spots; and his adversary (only) is bound to see that he stands and plays fair, otherwise the striker wins all the points he made by that stroke. 7. After a hazard has been won, the balls are to be separated, and the striker is to lead as at first. When a hazard has been lost in either of the corner holes, the leader is

obliged (if his adversary requires it) to lead from the end of the table, where the hazard was lost; but if the hazard was lost in either of the middle holes, it is at the leader's option to lead from either end of the table he pleases. 8. If the striker does not hit his adversary's ball, he loses one point; and if by the said stroke his ball should go into a hole, over the table, or on a cushion, he loses three points, viz. one for missing the ball, and two for holing it, &c. and he loses the lead. 9. If the striker holes his adversary's ball, or forces it over the table, or on a cushion, he wins two points; but when he holes either his own ball, or both of them, or forces either or both of them over the table, or on a cushion, he loses two points. 10. No person has a right to take up his own ball without permission from his adversary. 11. If the striker should touch or move his own ball, not intending to make a stroke, it is deemed an accident; and his adversary may put the ball back to the place where it stood. 12. If the striker forces his adversary's ball over the table, and his adversary should chance to stop it, so as to make it come on the table again, the striker nevertheless wins two points. 13. But if the same events happen to his own ball, the striker loses nothing by the stroke, and he has the lead: because his adversary ought not to stand in the way, or near the table. 14. If the striker misses the adversary's ball, and forces his own over the table, and it should be stopped by his adversary, as before mentioned, he loses one point, but retains the lead, if he chuses. 15. If the striker, in playing from a cushion, or otherwise, by touching the ball, makes his mace or cue go over or past it, he loses one point; and if his adversary requires it, he may put the ball back, and make him pass the ball. 16. If the striker, in attempting a stroke, does not touch his ball, it is no stroke; and he must try again. 17. If when the balls are near each other, and the striker by accident should make his ball touch the other, it is nevertheless a stroke, though not intended as such. 18. If the striker should make his adversary's ball go so near the brink of a hole, as to be judged to stand still, and afterwards should fall into the hole, the striker wins nothing; and the ball must be put on the same brink where it stood, for his adversary to play for the next stroke.—N. B. There is no occasion for challenging the ball if it stops, as some persons imagine. 19. If the striker's ball should stand on the brink or edge of a hole, and in playing it off he should make the ball go in, he then loses three points. 20. If a ball should stand on the brink or on the edge of a hole, and should fall into the same, before or when the striker has delivered his ball from his mace or cue, so as to have no chance for his stroke, in that case, the striker's and his adversary's balls must be placed in the same position, or as near as possible thereto, and the striker must play again. 21. The striker is obliged to pass his adversary's ball, more especially if he misses the ball on purpose; and the adversary may oblige him to place his own ball where it stood, and play until he has passed. 22. If the striker touches his own ball twice, or plays both balls from his mace or cue, so that they touch at the same time, it is deemed a foul stroke; and if discovered by his adversary, and a dispute should arise thereon, he has an undoubted right to appeal to the disinterested company then present; and the marker, if required, after desiring silence, must go round the table to each person separately, and be particularly careful to ask, if he has any bet depending thereon, if he understands the game, and the nature of the dispute then in

question; and if determined by the majority of the disinterested company, and the marker, if needful, to be a foul stroke, then it is at the adversary's option (if not holed) either to play at the ball, or take the lead. But if his adversary shall not discover it to be a foul stroke, then the striker may reckon all the points he made by the same, and the marker is obliged to score them. 23. No person has a right to discover to the player whether the stroke is fair or foul, until asked by him, or by him or his partner in a match of four. 24. If by a foul stroke the striker should hole his adversary's ball, he loses the lead. 25. If by a foul stroke the striker holes his own or both balls, or forces his own or both balls over the table, or on a cushion, he loses two points. 26. If the striker plays on a ball when it is running or moving, it is deemed a foul stroke. (See art. 22.) 27. If the striker plays with both feet off the floor, without the permission of his adversary, it is deemed a foul stroke. (See art. 22.) 28. If the striker plays with a wrong ball, he loses the lead, if his adversary requires it. 29. If the balls should be changed in a hazard, or on a game, and it is not known by which party, the hazard must be played out by each party with their different balls, and then changed. 30. If the striker plays with his adversary's ball, and holes or forces the ball he played at over the table, &c. it is deemed a foul stroke. (See art. 22.) 31. If the striker plays with his adversary's ball, and holes or forces the ball he played with over the table, &c. he loses two points; and if he misses the ball he plays at, then he forfeits three points. 32. If the striker plays with his adversary's ball, and misses, he loses one point; and if his adversary discovers that he has played with the wrong ball, he may part the balls, and take the lead. 33. In all the before-mentioned cases of the striker playing with the wrong ball, (if discovered) his adversary must play with the ball the striker played at throughout the hazard, or part the balls, and take the lead. 34. Whoever stops a ball when running, loses the lead, if his adversary does not like the ball, he has to play at the next stroke. (See art. 22.) 35. If any one retains his adversary's cue or mace when playing, it is deemed foul. (See art. 22.) 36. If the striker stops or puts his own ball out of its course, when running towards a hole, and adjudged by the marker, and the disinterested company then present, to be going into a pocket, if he missed the adversary's ball he loses one point; and if going into a hole by the same stroke, three points. 37. If any player stops or puts his adversary's ball out of the course when running towards or into a hole, or puts his adversary's ball into a hole, it is deemed a foul stroke. (See art. 22.); and he is also subject to similar penalties as stated in article 36. 38. He who shakes the table when the ball is running, makes it a foul stroke. (See art. 22.) 39. He who throws his mace, cue, or stick upon the table, so as apparently to be of any detriment to his adversary, makes it a foul stroke. (See art. 22.) 40. He who blows on the ball when running, makes it foul. (See art. 22.) And if his own ball was running towards or near the hole, he loses two points. 41. He who leaves the game before it is finished, and will not play it out, loses the game. 42. Any persons may use either mace or cue, or change them in playing, unless otherwise previously agreed on; but when the parties agree to play mace against cue, the mace-player has no right to use a cue, nor has the cue-player any right to use a mace during the game or match, without permission. 43. When a person agrees

to play with the cue, he must play every ball within his reach with the point of it; and if he agreed to play with the butt, he has no right to play with the point without permission: and also when agreed to play point and point of the cue, neither of the parties has a right to use a butt during the game or match, without leave, &c. but they have each a right to play with the point of a long cue over a mace, &c.; and likewise when the parties agree to play all point with the same cue, they have no right to use any other during the game or match. 44. Whoever proposes to part the balls, and his adversary agrees to it, the proposer loses the lead. 45. Two missings do not make a hazard, unless it is previously agreed on to the contrary. 46. In all cases, the betters are to abide by the players on the determination of the hazard, or on the game; and the betters have a right to demand their money as soon as their game is over. 47. Every person ought to be very attentive, and listen for the stroke before he opens the door of a billiard room. 48. The striker has a right to desire his adversary not to stand facing nor near him, so as to annoy or molest him in the stroke; and if he is impeded by his adversary, or any spectator, he has a right to strike again. 49. Each party is to attend to his own game, and not to ask—If his adversary's ball be close?—If he touches his ball?—If he can go round the ball?—nor any like question; nor is any person to be set right, if going to play with the wrong ball. 50. Spectators should stand from the table, and give room for the players to pass round. 51. The parties who play ought to be particularly careful and attentive to the hazard or the game, more especially when any bets are depending upon it; for even if they play carelessly, the bets must be decided by their strokes. 52. No person in the room has a right to lay more than the odds on a hazard or on a game. But should appeal to the marker; or to the table of the odds, which ought to be hung up in the billiard room for inspection. 53. Each person who proposes a bet, should name the sum, and likewise be very careful not to offer a bet when the striker has taken his aim, or is going to strike, lest it may disturb or interrupt him; and no bet ought to be proposed on any stroke (at the losing game especially) that may be supposed to have any tendency to lessen or to influence the judgment of the player. 54. If any bets are laid on the hazard, and the game is eleven, and the striker loses the game by a miss, and should afterwards go into a hole, it cannot be a hazard, the game being out by the miss. 55. If A proposes a bet which is accepted by B, it must be confirmed by A, otherwise it is no bet. 56. When four persons play, each party may consult with and direct his partner in anything respecting the game, &c. and the party who misses twice before a hazard is made, is out, and it is his partner's turn to play; but if, after the two missings have been made by the party, his adversary should hole a ball, so as to make a hazard at the stroke following the said two missings, yet the party who did not make the two missings is to play, as he cannot be supposed to be out, who has not made a stroke.

White Losing Game, played with two white Balls.—The game is twelve in number, the points of which are reckoned by losing and double, or winning and losing hazards.

When a person is tolerably well acquainted with the winning game, he should then learn the losing game (the reverse of the winning,) which is a key to billiards

in general. It depends entirely upon the defence, and the knowledge of the degree of strength with which each stroke should be played, either to defend or make a hazard: for if a person who has a competent knowledge of the game should not have a hazard to play at, he must endeavour to lay his own ball in such a position, that his adversary may not have one to play at the next stroke. For a losing game, hazard is much more easy to be made, when well understood, than a winning game hazard is in general. For an account of the rules, see *Hoyle's Games*.

The White Winning and Losing Game is a combination of the two preceding; and all the balls put in by striking the adversary's ball first, reckon towards the game.

Red or Carambole Winning Game, played with three Balls, two white and one red.—The game is 16 or 18 in number, formed from winning hazards and caramboles.

There are two methods of playing this game; one by the players striking alternately, in which the number of points is usually 16; the other where the players follow their successful strokes, and then the points are 18: the latter mode is now generally used.

The red or carambole winning game is full of variety; and there being so many chances in it, which make it a game of great uncertainty, the odds of it are not calculated, but bets are generally laid according to fancy, or to the custom of the table where they are usually played at. For the rules, see *Hoyle*.

Red or Carambole Losing Game, played with three Balls, two white and one red.—The game is 16 or 18 in number, as in the red winning game, scored by caramboles, losing and double hazards.

The red or carambole losing game requires greater judgment than the winning, and depends materially on the skill of the player; the chances in it may happen sometimes to vary more than at the winning carambole game, and especially if the players do not properly understand the skilful part. For the rules, see *Hoyle*.

The Simple Carambole Game, played with three Balls, as in the others.—The game is 12 in number, arising from caramboles and forfeitures.

This game, possessing very few chances, requires both skill and judgment, and is seldom played alone, but generally by able proficients against the winning and losing, or the winning game of novices, considered equal to giving 15 out of 24 points. It is also played two different ways; in one the hazards lose, in the other they are not reckoned; the first mentioned is the customary method, where the striker, upon making a hazard, loses as many points as he, by that stroke, would have gained in either the winning or losing game. For the rules, see *Hoyle*.

The Winning and Losing Carambole Game, played with three Balls, two white and one red.—The game is 21 or 24 in number, reckoned both from winning and losing hazards and caramboles.

This game, now very frequently played, is, agreeable to its title, a combination of the foregoing red winning and losing carambole games, and to which all the rules and regulations, both for the white and red games, are applicable, except where any of them may happen to be contradictory to another, and then the rules for the winning games are to have the preference.

The Bar-hole Game.—This is so styled, because the hole which the ball should be played for is barred, and the player strikes for another hole. When this is played

against the common game, the advantage to the last mentioned is calculated at six points.

The Bricole Game.—Bricole signifies being required to strike a cushion, from whence the ball is to rebound so as to hit that of the adversary, reckoned equal to giving eight or nine points. When both parties play bricole, the game is ten scored from bricole, hazards, and forfeitures.

The Caroline Game.—This is played either on a round or square table with five balls, two white, one red, another blue, and the caroline ball yellow. The red ball is to be placed on its usual spot, the caroline ball exactly in the middle of the table, and the blue ball between the two at the lower end of the table. The striking spot is at the upper end, in a parallel line with the three balls. The game is 42 scored from caramboles and hazards; the red hazard counts three, the blue two, and the yellow, when holed in the caroline or middle pocket, is reckoned as six points.

Choice of Balls Game.—In this game the player chuses his ball each time, an incalculable advantage generally played against the losing and winning game.

The Commanding Game.—At this game the adversary fixes upon the ball which the striker is to play at, reckoned equal to having 14 points out of 24; usually given by a skilful player against the common game of an indifferent one.

The Cushion Game.—This game consists in the striker playing his ball from the top of the baulk cushion instead of following his stroke upon the table, and is generally played in the winning or winning and losing game, reckoned equal to giving six points.

The Doublet Game.—This Game is ten in number, played with two balls, most commonly against the white winning game, and no hazard is scored unless made by a reverberation from the cushion, calculated as equivalent to giving five points.

The Four Game, consists of two partners on each side at any of the common games, who play in succession after every winning hazard lost. See rule 56 of the *White Winning Game*.

The Hazards.—So styled as depending entirely upon making of hazards, no account being kept of game. Many persons may play at a table with balls that are numbered, though, to avoid confusion, seldom more than six play at once. The person whose ball is put in pays a fixed sum for each hazard to the player, and he who misses pays half the same to him whose ball he played at. The only general rule is, not to lay any ball a hazard for the next player, which may best be done by always playing upon him whose turn is next, and either bringing his ball close to the cushion, or putting it at a distance from the rest.

The Limited Game is very seldom played. In it the table is divided by a line, beyond which, if the striker passes his ball, he pays forfeit.

The One-hole Game.—All balls that go into one hole are counted at this game, and the player who best lays his ball at the brink of that particular hole, has the advantage. The lead should be given from that end of the table where the last hazard has been made.

The Russian Carambole.—This game varies from the common carambole in the following particulars:

The red ball is to be placed upon the usual spot; but the player, at the commencement of the game, or after his ball has been holed, is at liberty to place it where he pleases. The leader, instead of striking at

the red ball, should lay his own gently behind it, and the opponent may play at either of them. If the said opponent plays at and holes the red ball, he scores three; then the red ball is to be replaced upon the spot, and the player may take his choice again, always following his stroke till both balls are off the table, he gains two points for every carambole; but if, in doing that he holes his own ball, then he loses as many as he would otherwise have obtained; and if he strikes at the red ball, caramboles and holes that ball and his own, he loses five points; and when he holes all three balls he loses seven, which respective numbers he would have won had he not holed his own ball.

Fortification Billiards.—First, there are ten wooden forts in the form of castles, which are loaded with lead, so that they may keep their places. In the front of each fort, at the bottom, is an arch to admit the ball, which is to be put through it to attack the fort, and within each arch a small bell is hung. Secondly, the pass through which each of the adversary's attacking balls must pass, before a fort can be taken. Lastly, the grand batteries, and ten flags or colours.

Two of the forts, called the grand forts, are to be made larger than the rest, and to have an arch cut through them of the same size as the others. Five of the forts, including one of the grand forts, one of the batteries, and five of the flags or colours, are usually painted red, and the forts and battery like brick-work, which denotes them to be English; on each fort one red flag is to be hoisted on the centre of its front. The other five forts, grand fort included, battery, and colours, are to be of a white colour; the forts and battery to be painted with black like stone, are called French, and one white flag to be hoisted on each.

The pass, which serves for the purpose of both parties attacking balls to go through, is to be made in the form of the grand forts, but rather longer for distinction, and to have an arch of the size of the grand forts, and painted of different colours, viz. one of the ends where the arch is of a red, to continue half way of each side, and the same on the top; the other end of the arch is to be white, and to continue in the same colour over the other half. There are likewise two flags to be hoisted on the pass, viz. one red and the other white; the red to be hoisted at the English and the white at the French end. The pass is to be placed in the centre of the table, the red end facing the English, and the white end the French forts.

The limits of each party's quarter is from the end cushion, where his forts are placed, to his pass on each side of the table. The English forts are to possess one end of the table, called the English quarter, and the French forts the other end, called the French quarter. The two forts in each quarter in the first angle from the pass are to be taken first, and are called the advanced forts. The two forts in the second angle are to be taken next, which are called the reserved forts. Lastly, the grand fort, with the battery placed before it, is the last to be taken.

The height of the advanced and the reserved forts is to be $5\frac{1}{2}$ inches, the breadth and length of the advanced forts 5 inches to the square, and the length of the reserved forts are $5\frac{1}{3}$ inches, and the back of them to be rounded off. The height of the grand forts is to be $5\frac{1}{4}$ inches, the breadth and length $6\frac{1}{4}$ inches. The batteries are made in a triangular form, the height of them are 3 inches, the breadth at the extremity are $2\frac{1}{2}$ inches, and

the length $3\frac{1}{2}$ inches. The height of the pass is $5\frac{1}{2}$ inches, the breadth $6\frac{1}{4}$ inches, and the length 7 inches. The height of the concave in the forts where the attacking ball must enter, is 3 inches, the breadth $2\frac{1}{2}$ inches, and the depth $2\frac{3}{4}$ inches.

The bell which is to be within the arch in each fort must be hung $1\frac{1}{2}$ inch within it.

The balls which are to be played with at this game, are to be $1\frac{3}{8}$ inch diameter.

Rules.—The game is twenty in number.

1. The player who strikes the opposite cushion, and brings the ball nearest the cushion he struck from, shall have the first stroke, and also the English side of the forts, and must begin the attack.
2. Each party has one attacking, and two defending balls.
3. The balls are placed on the spots, the attacking ball in the middle, and the defending balls on each side of it.
4. The ball for the attack, on the English side of the forts, must be spotted with red, and the defending balls with small black circles.
5. The ball for the attack on the French side of the forts must have white, and the two defending balls eight black spots on each.
6. Before you can attack any of the forts, you must make the pass.
7. When the pass is made, you must take down your adversary's colours, and then attack either of his advanced forts, which must be taken first.
8. If, after you have made the pass, you do not take down your adversary's colours, you must make the pass again from your own side of the forts; but you must not return to the spot.
9. If you take either of your adversary's forts, after you have made the pass, and have not taken down your adversary's pass colours; you lose two points, and must return to your spot again.
10. After you have regularly made the pass, as in art. 7, and have taken a fort, you must return to your middle spot again.
11. When you have taken a fort, you win 4 points.
12. If you do not take down your adversary's colours when you have taken his fort, you must take the said fort again, and must be put back those four points you won by the same.
13. Missings at this game reckon nothing.
14. After you have regularly made the pass, you are not obliged to go through it again.
15. In each fort there is a bell, which gives notice at being taken. The bell must be made to ring, otherwise the fort is not taken.
16. The besieged may defend his own forts, or may send his attacking ball into the besiegers quarter to attack his.
17. The besieger must take his adversary's forts with his attacking ball.
18. If the besieger should take his adversary's fort with either of his defending balls, he loses two points, and returns to his spot.
19. If the striker plays with either of his adversary's balls, he loses two points, and if he played on either of his own balls, that must be put on its proper spot again, if his adversary requires it.
20. Either party may send his defending ball or balls into his adversary's quarter.
21. After having taken the two advanced forts, you must take the two forts in the next angle, which are called the reserved forts; and lastly, the grand fort.
22. He who does not take the forts according to the above direction, and takes either of the last for the first, loses two points, and must return to the proper spot.
23. After a fort has been taken, or a ball holed or forced over the table, the striker is bound to place the ball on its proper spot; and if he does not, he shall reckon nothing for any forts, &c. he shall take during the time the ball is out of its place.
24. After having taken a fort, either by storm or otherwise, if the adversary takes the ball out of the fort.

though he does not take down his colours, nevertheless the said fort is deemed as taken, and the colours are to be taken down. N. B. Taking a fort by storm is, when the party having made his utmost efforts finds it so well defended by his adversary, that he is obliged to have recourse to stratagem, that is, by laying his ball in a proper angle, and striking the ball against the end cushion, and bringing the ball back again into his adversary's fort. 25. If the striker force either of his adversary's balls into his own fort which has not been taken, he makes him a prisoner of war, and wins six points. 26. If the striker force either of his adversary's balls into his own fort which has been taken, it is no prisoner of war, but the said striker wins two points. 27. If the striker forces either of his adversary's balls into his adversary's fort, he wins two points. 28. If the striker holes any of his adversary's balls, for each ball so holed he wins two points. 29. If the striker holes his own ball or balls, for each ball so holed he loses two points. 30. If the striker force his adversary's ball or balls over the table, or on a fort or cushion, for each ball he wins two points. 31. If the striker forces his own ball or balls over the table, &c. he loses two points for each ball. 32. If the striker forces his adversary's ball over the table, or on a fort or cushion, or into a hole, and regularly takes his adversary's fort by the same stroke, he wins six points. But if by the same stroke the striker's ball should go into a fort which has been taken, or is out of the angle, he loses two points. 33. If the striker holes his own or his adversary's ball, or forces them over the table, or on a fort or cushion, he loses two points. 34. If the striker forces his ball into any of his own or adversary's forts, which had been taken, or into any of his adversary's forts out of the angle, he loses two points. 35. When a ball is holed or forced over the table, or on, &c. such ball is to be placed on its proper spot; but if it happens that the spot should be occupied by another ball, then the ball is to be placed behind, so as not to touch the other ball. 36. Whoever takes a fort after it has been regularly taken, and the colours are down, loses two points. 37. When the adversary's ball is out of sight (that is, lying behind a fort so that it cannot be seen,) and the striker wishes to strike the cushion first, and hit the said ball backwards, by giving warning, saying, *I do not see*, if he should hit the said ball, he wins two points; but if he should not hit the ball, he loses two points. 38. If by this stroke, the striker should hit the ball, and hole his own ball, or force it over the table, or on a fort or cushion, or into either of his own forts, or into either of his adversary's forts, which has been taken, or is out of the angle, (See 21. and 22.) he loses two points. 39. If either of the adversary's balls should lie before either of the striker's forts which has not been taken, and (the said ball being out of sight) the striker wishes to strike the cushion first, and hit the said ball backwards, to make a prisoner of his adversary's ball, by saying, *I do not see*, if he hits the ball, he wins two points, and if he makes a prisoner of his adversary's ball, he wins six points more, and his adversary's ball must return to its proper spot. 40. When the striker gives warning, saying, *I do not see*, his adversary, or the company, have a right to be judges, or the marker, in case of any dispute. 41. If the striker holes, or, &c. either of his adversary's defending balls, it is at his adversary's option to place the said ball on either of the proper spots, if they are both vacant. 42. Whoever touches both balls with mace or cue, makes a foul stroke.

He cannot therefore reckon any points made by the said stroke, if it is discovered by the opponent, and proved to be so by the company and the marker; but if it is not discovered, the marker is obliged to reckon all the points made by the stroke. But if the said stroke is proved to be foul, then it is at his enemy's option either to break the balls, or to make him return to his proper spot. 43. If the striker makes a foul stroke, and holes his own ball, or forces it over the table, &c. he loses two points for each of his own balls so holed or forced over the table; and it is at his adversary's option to part the balls. 44. If the striker moves the ball, it must be put back to the proper place it was moved from. 45. Blowing on any of the balls when running is deemed foul, (See art. 42.). 46. If the striker, by blowing on his own ball, should put it out of its proper course, especially when running near a hole, he loses two points; and it is deemed foul, (See art. 42.) 47. Stopping a ball with stick or otherwise, after the stroke, is deemed foul, (See art. 42.). 48. Playing with both feet off the floor, without permission from his adversary, is deemed foul, (See art. 42.) 49. Playing upon a ball when running, is deemed foul, (See art. 42.) 50. Whoever retains his adversary's cue or mace, when playing, loses two points; besides it is foul, (See art. 42.) 51. Whoever gets the first twenty points, each fort being regularly taken is four points, wins the game. 52. When four parties play a double match, he who plays before his turn loses two points. N. B. The rest of the necessary rules are the same as the rules, &c. of the White Winning Game. See Hoyle's *Games*, and the *Dictionnaire des Jeux* in the *Encyclopedie Methodique*. Some account of the principles of the game of billiards may be seen in the *Dictionnaire des Jeux Mathematiques*; *Journal de Physique*, xlv. 45; *Observations par Rozier*, xl. 19; and Dr Young's *Natural Philosophy*, vol. i. p. 81.

BILSTON, a large village of England, in Staffordshire, between Wolverhampton and Birmingham. It is about a mile and a quarter long, and contains numerous manufactures of japanned and enamelled goods. The buckle chafes manufactured here are particularly celebrated. The country about the town is covered with smelting furnaces for iron ore, forges, and slitting mills, and abounds with mines of coal and ironstone. An orange coloured sand, which is in great request among founders, is also found here; besides a quarry, consisting of twelve horizontal strata of remarkable stones, gradually increasing in thickness downwards. These stones are principally employed in the formation of cisterns, troughs, &c. By means of numerous canals, Bilston communicates with the rivers Dec, Mersey, Ribble, Ouse, Derwent, Trent, Severn, Humber, Thames, and Avon. Number of houses in 1801, 1246. Population 6911, of whom 2414 were returned as employed in trade and manufactures. See Shaw's *History of Staffordshire*. (j)

BINARY ARITHMETIC. See ARITHMETIC *Index*.

BINARY LOGARITHMS, are a species of logarithms contrived and calculated by M. Euler, (*Tentamen Nova Theoriae Musicae*, chap. vii.) for facilitating musical calculations; wherein 2 is made the unit, or modulus, instead of 10, as in the common logarithms, or 1 in the hyperbolic logarithms.

In these logarithms, the powers of 2 have successively 1, 2, 3, 4, &c. for their logarithms, as in the following table, for the first 10 numbers, viz.

Numbers.	Binary Logarithms
1	0.000000
2	1.000000
3	1.584963
4	2.000000
5	2.321928
6	2.584963
7	2.807356
8	3.000000
9	3.169925
10	3.321928

The great ease with which musical calculations are performed by the binary logarithms, owing to the same representing the *decimal values* of the intervals, in terms of the *octave* as unity, induces us to give here another table of these logarithms, answering to the several elementary intervals, which are represented in Plate XXX, on which there was not room for this column.

Charac- ters.	Names of Intervals.	Reciprocals of the Bina- ry Logar- ithms.
m	Minute	0.000045
f	Lesser Fraction	0.000259
d	Medius Fraction	0.000893
F	Greater Fraction	0.001411

6 th	Minor Sixth	0.678072
VI.	Major Sixth	0.736966
VIII.	Octave	1.000000

By help of the above, and the tables of equations among the musical intervals, given under the several

articles APOTOME, COMMA, &c. the binary logarithms of any other interval of the diatonic scale may be found. (e)

BINCHE, a town of France, in the new department of Temmapes, situated on the banks of the river Hairre. It was burned in the year 1554 by Henry II. of France, but was soon afterwards rebuilt. Population 3798. (j)

BINGEN, a town of France, in the new department of Mont-Tonnerre, situated near the confluence of the Rhine and the Nah, the latter of which is crossed by a fine stone bridge. The corn which supplies the neighbouring country passes through this town, which also furnishes it with drugs, and articles of foreign commerce. Near Bingen is the famous Bingen loch, or gulf of Bingen, formed by the conflux of the Nah and the Rhine, by a chain of narrow rocks, where the water precipitates itself in cataracts. The navigation of this part of the Rhine is very dangerous. Not far from Bingen is a small island in the Rhine, called *Maustburn*, or the Tower of Rats, in consequence of a tradition, that the archbishop of Mentz was devoured by these animals, for having compared the poor to rats that preyed upon the substance of the rich. The fortifications of Bingen were destroyed in 1689 by Louis XIV., but it was again fortified by the desire of Bonaparte, when he was first consul. Population 2663. E. Long. 7° 33', N. Lat. 49° 54'. (π)

BINOCULAR TELESCOPE, the name of an instrument invented by Father Rheita, in which the object was observed by both eyes. Binocular telescopes have been long completely exploded. (w)

BINOCULUS, a genus of crustaceous animals that inhabit fresh water. See CRUSTACEA. (f)

BINOMIAL THEOREM. See ALGEBRA *Index*.

BIOGRAPHY, (from *βίος*, *life*, and *γραφω*, *to write*;) is a species of history which describes the lives of persons of eminence. In tracing the history of biography, we find it at first, in all countries, in the hands of the minstrels. The exploits of the chiefs were the subject of their song; and, as their heroes were raised into demigods, actions were ascribed to them surpassing human ability. This was the fabulous age of biography, when nothing was too marvellous for credulity. In Iceland and in Arabia the harper was the first historian; and both in ancient and modern Europe, the period of youthful romance preceded the sober day of truth. Legitimate biography was scarcely known in Greece till that country had passed the age of manhood; for what was done by Xenophon, in the institution of Cyrus, when Athens was in its glory, is of too equivocal authority to be classed under that head. It was not till the commencement of the 2d century, that Plutarch gave to biography the place which it now occupies among the departments of literature; and to him we are indebted for a more intimate acquaintance with the principal characters of antiquity, than we have with many persons of the first distinction in modern times. Writers of greater elegance, and of more philosophical views, may have followed in his track, but none have succeeded better in accomplishing the great ends of this species of writing, in combining entertainment and instruction, in stamping upon his productions the indubitable character of truth, in presenting a near and familiar view of the subjects of his records, and in filling up the sketches which the historian is obliged, by the nature and extent of his design, to leave to the biographer. During the long night of ignorance which preceded the revival of

learning in Europe, biography, degraded from the rank it once held, was enlisted in the service of superstition. The only men of letters in those times were the ecclesiastics, who were disqualified, both by credulity and artifice, for the office of the historian. In their hands biography exhibited a strange mixture of truth and falsehood, gravity and puerility, simplicity and fraud. Fabulous without being romantic, wanting both the authority of truth and the grace of fiction, their tales of wonder could neither instruct the judgment, nor delight the imagination. The subjects of their pen were supplied by the calendar of saints, some of whom were adorned with great virtues, and displayed a heroism in the defence of their opinions which entitle them to the veneration of posterity; whilst others had no better title than is conferred by successful hypocrisy spreading the cloak of sanctity over pride, avarice, and ambition. The narrative of their lives, instead of developing the nature of man, and marking the progress of passion or of intellect, was for the most part a record of nothing but miracles pretended to have been performed by themselves, or entailed upon their ashes. Since the restoration of letters, biography has extended itself through a much greater space than it occupied in ancient literature. This was a natural consequence of the invention of the art of printing, by which the sources of information are multiplied, and made more certain, as well as more easy of access. To this advantage we are indebted for Bayle's elaborate work, which even his great industry and acuteness of research could not have produced without it. The wide circulation of books, and the prodigious increase of the number of readers, to whom no literary productions are more generally acceptable than well written biographies, have engaged a good portion of talent in this department; and though it is true, that, in the long catalogue of biographies which the last century has supplied, many will be found which have little to recommend them, either in the subject or in the execution, a list might easily be made out sufficiently honourable to modern literature. In this number, the works of such men as Middleton, Jortin, and Johnson, are entitled to particular notice, as specimens of fine writing, and as depositories of useful and ingenious remark; and from the eulogies of the French academicians, and some periodical publications of our own country, a selection might be made, affording a display of more than ordinary elegance and ability.

The rules which have been laid down by criticism for historical composition are generally applicable, but with some qualification, to the style proper for biography. If it wants simplicity, the work will appear to be rather the production of the rhetorician than of the honest narrator; if it wants dignity, or that grace which is always nearly akin to dignity, it will degenerate into the vapid garrulity of the story-teller. A well-written biography, however, will have an air of much greater familiarity than belongs to the most approved historical style. We are best entertained, and perhaps not least instructed, by memoirs which abound in anecdotes; and to communicate them in a style which mimics the majestic march of the history of nations must provoke ridicule, the proper chastisement and best corrective of affectation. In works of this sort, splendor of imagery, elaborate description, and rhetorical ornament, in general, would want propriety, and therefore beauty; their character should be that of elegant simplicity.

By whatever rule the comparative value of literary
VOL. III. PART II.

productions ought to be estimated, biography will be found to occupy no inferior place. Its object, like that of poetry, is both to delight and to instruct, and this in effects, in common with all authentic history, by the relation of facts. It invites the attention, even of the most indolent, by the ease and familiarity of its address; it teaches, not by precept, but example; and is heard the more willingly, because it speaks rather as a companion than a monitor. The biographer, sitting in the circle of his hearers, and assuming no superiority of talent, or office, enforces the best lessons of morality in the best possible way. But though his pretensions are not arrogant, his task is not therefore easy, and within the compass of every ordinary capacity. The art of narration, indeed, seems at first view to require no endowment which rises above mediocrity. Diligence in the investigation of facts, fidelity, perspicuity, and ease in the relation, are the great requisites in historical composition. The poet, if he aspires to the first order, must soar to the highest heaven of invention; and if he would be enrolled in any order of his art, his track must rise far above the ordinary level, and lead through scenes of beauty and of interest. He may want the truth, but not the fire of inspiration: and his conceptions must swell with an enthusiasm, that, like charity, will cover a multitude of faults. But the historian has fulfilled his promise, when he has made his reader acquainted with that portion of the history of man which he proposed to delineate, by a faithful narration of the facts in the order of their succession, and by referring events to their proper causes, or to such at least as will be thought most probable by a judge of human character and actions. What is so simple in the design will scarcely be thought difficult in the execution, unless by those who have learnt that simplicity is the last attainment of art. The history of empires and nations, however, embracing a multitude of agents, and great variety of events, to which their true place and operation must be assigned, is evidently a work far above the execution of limited capacity. To reduce the chaos of events to their proper order; to exhibit them in their actual connection; to draw with a faithful pencil the portraits of the principal agents; to describe the endless diversities of character, and the doubtful lights and shades of virtue and of vice, in each maintaining, at the same time, a strict regard to testimony and to truth,—is a design of such magnitude, that it is no wonder, if, of those who have made the attempt, few have been very successful in the execution. Here the theatre is wide, the drama extended, the characters various and numerous, the incidents almost inexplicably interwoven, and the passions engaged in perpetual conflict. But biography exhibits persons, not empires; it traces the chain of events, not through centuries, but during the short period of the life of one man; and in this period, of those events only in which he had a principal concern. It attends upon history as the artist upon the navigator, who, with his pencil in his hand, is contented to depict single and detached spots, where the view is concentrated, and the outline commanded at a single glance. Whilst history traces the actions and progress of man, from the first twilight of tradition to the present hour, presenting him in patriarchal simplicity, and invested in all the culture of civilization, shewing the same creature through all the variety of political arrangement, biography chooses, from the multitude of mankind, persons on some account distinguished from the rest, and, subjecting them to particular inspection, presents a

chart of their lives for the benefit of succeeding generations.

Biography, in this view of it, may be properly considered as a supplement to history. Where the historian could give only a sketch, the biographer presents us with a finished picture. He selects from historical groups the most distinguished figures, advances them into the fore ground, and gratifies us with the means of a nearer contemplation. His ory proposes to introduce us to the knowledge of particular persons, and their actions, so far only as is necessary to carry on the chain, and mark the connection of events which it describes: it shews the soldier in the field, the statesman in the senate, and sometimes in the cabinet; but it does not lead us within the threshold of his retirement, and exhibit him in the interesting relations of domestic life: it gives us the public, but not the private man; or no more of the private man than is necessary to the elucidation of public transactions. When his principles, passions, and conduct, have borne with powerful influence upon the great stream of human action, they are brought into nearer view, and subjected to closer inspection. Still he is seen but at a distance in the great historic gallery; the finer shades of manners, from which actions and characters of the same class derive difference and individuality, are seldom distinguished in this general survey. Here biography steps in with peculiar advantage; it leads us into the familiar walks of life; it shews the monarch in his family, the hero in the circle of his friends, the orator no longer declaiming in the senate or the hall, but conversing on the level of his associates, and unbending his eloquence to negligence and playfulness; it enables us to see the great man divested of his state, the conqueror descended from his car, the mock-patriot in his sphere of private oppression, and the true one supported under public injustice and ingratitude by the lofty consciousness of rectitude.

Biography being one of the numerous departments of history, it has some objects common to them all. It proposes to ascertain and record what is true in fact, and to this end it separates the fabulous from the authentic, discharges the false colouring of prejudice and party, weighs opposing testimonies, exposes the representations of falsehood, and labours, like the Cretan judge, to administer impartial justice to the dead. To accomplish this task, it is necessary that the biographer be capable of patient investigation and diligent research. Not only must his love of truth raise him above the cloudy region of prejudice and faction; he must be endowed with no ordinary share of sagacity, that he may detect specious fabrications, and through the distortions of envy, and the exaggerations of flattery, discover what is probable and credible. Another, and a principal object of biography, is to record what is instructive in example. It has been remarked, and perhaps truly, that there is no man, however confined his capacity and sphere of action, a faithful narrative of whose life would not furnish lessons of useful instruction; if it disclosed nothing new in human nature, it might at least serve to illustrate and confirm what was already known. But since equal benefit is not to be derived from every life, biography takes out of the long roll of those who have performed the same journey before us, the names of those, whose wisdom or whose weakness, whose virtues or whose errors, are likely to make the deepest and most salutary impression; it thus gives us an opportunity of enriching our own minds with the treasures of experi-

ence, which have been collected by others, and collected often at a great price of labour and of pain. A question has been made by the critic and moralist, respecting the epic poem, whether it is necessary that the hero of the piece be distinguished for virtue, as well as for the splendour of his qualities and exploits; and, though the poet has not always chosen or constructed his story in conformity to such a rule, it must be owned, that had he done so, he would have rendered an important service to the interests of virtue, instead of leaving it, to say no more, very questionable, whether his productions have not, in some instances, militated against them. Unless the hero be encircled with a radiance sufficient to dazzle even a strong sight, his poem will soon be found to be any thing but poetry; and if a character intrinsically bad be made powerfully to engage admiration, the principles of virtue must be much better understood, and more generally, and at a much earlier age settled in the mind than they are in fact, to prevent admiration becoming sometimes the forerunner of imitation. The same objection does not lie, however, against making a man of depraved manners the subject of a biographical memoir; for in such cases it is the fault of the biographer, and not an inevitable result of that species of writing, if the admiration of splendid talents is made to prevail over the detestation of depravity. Biography proposes to rescue what is memorable from the spoils of time. In every age, men of more than ordinary endowment, have risen above the plain of their cotemporaries, who, by their actions or writings, have not only commanded an extensive influence over the times in which they lived, and the people with whom they mingled; but even over succeeding ages, and over nations far removed from the immediate sphere of their activity. Destroyers, or benefactors of mankind, they were the volcano whose eruption carries desolation in its course, or the heights that send their streams to fructify the land, and give plenty to the inhabitants. We contemplate the records of their lives as monuments of generations which have been long extinct; and travelling up the stream of time, we gain a sort of pre-existence to the short life which is allotted us among our cotemporaries. We converse with the greatest and wisest of our progenitors, and are sometimes privileged to enjoy a sort of confidential acquaintance with them, to visit their solitude, and penetrate the recesses of their minds, the principles and motives of their conduct. It is also consolatory to know, that though the common law of our nature extends its rigorous necessity to the wisest and the best, as well as to the least and worst of mortals, yet every memorial of them shall not perish with their lives; their memory, if not their existence on earth, shall be perpetuated, and shall kindle a kindred flame in the breast of their successors, when they and their ashes have long lost "their wonted fires." One end of biography is to add to the stock of human knowledge, and of that part especially which it most concerns all men to possess,—the knowledge of human nature. In the study of man, as well as of every other species of being, if we would not substitute fiction for reality, we must begin with particulars, and proceed to what is general. The individual must be known before it can be ranged under its proper class. Nothing so much retarded the progress of knowledge as the pursuit of a contrary method through a long succession of centuries. The philosopher was degraded into the mere schoolman, and was employed in forcing and torturing natural objects into a conformity to his factitious cate-

gories and predicaments, instead of pushing his inquiries by observation and experiment into the actual properties of surrounding beings. A like error is committed by him who first constructs an elaborate theory of man, and examines the individuals with no other view than to fit them to his preconceived philosophy. Some errors in morals, and more in metaphysics and theology, might have been avoided, had the only method of science been pursued, the study of particulars; had the philosophy of man been built upon the knowledge of the individuals which compose the species. In such a pursuit, biography offers its ready help, by making men of every age, nation, temperament, profession, and character, pass in review; and enabling the philosophical speculatist to form his opinions respecting the nature of man, not from dogmas, apothegms, and maxims, whether fashioned in the cloister, or collected in the court, but from actual survey, and critical examination of the nature of man, exhibited under all the diversified forms of individual existence.

But the object which biography especially proposes to accomplish, and for which it has advantages above every other species of writing, is, to make entertainment the vehicle of information and improvement. Its superior utility on this account will appear by comparing it with general history on the one hand, and on the other with tales of fiction. A great portion of history is occupied in relating the intrigues of courts, the operations of the camp, the adjustment of treaties, and the causes of the rise and decline of nations, in poising the interests of different states, and unravelling the intricacies of state policy. These details, however interesting to the statesman, the politician, and the soldier, are capable of little practical application to ordinary life, and administer more to the gratification of the curious than to general improvement. To a great proportion of readers, they are found even wanting in entertainment. The subjects of narration are too remote from their own observation and experience, to awaken any very powerful sympathy; and the information which they convey is desired rather for ornament than use. But in the perusal of the lives of eminent persons, we contemplate the man as well as the politician and the warrior. By a nearer approach to him, by seeing him in different relations, private as well as public, and following him step by step from the cradle to the grave, we participate in his feelings, enter into his designs, and appropriate, in some measure, the results of his experience. But whatever means the biographer may possess of making instruction steal upon the reader in the way of entertainment, fiction appears to have some advantages which are not to be found even in his department. In constructing a tale of fiction, the author may shape his characters, and connect incidents in any way that does not violate probability, and trespass beyond the limits of nature. Within this line he has license to range at large, and collect and combine whatever, and in what manner soever he may think best suited to the accomplishment of his design. He may throw into the lives of his chief actors the experience of many ordinary, and even extraordinary lives, and contrive every passage of them with such skill and address, that each shall point to some moral, or lead to some train of useful reflection. He can suppose facts with a direct reference in every step of his invention, to the conclusion which he wishes to be drawn from them; while the historian must take facts as they are, connect them

as they are actually connected, and pursue utility in no track but that of historical truth. This restriction, it must be admitted, narrows the basis of his structure; but it gives it at the same time a solidity and stability which fiction wants. The latter, indeed can produce correct imitations of nature and of manners; it can also describe a series of actions that shall inculcate lessons of wisdom not different from those which proceed from actual experience; but the dignity and impression of truth are still wanting; the orders which are issued are good, but they have not the seal of authority. We are delighted, but little practical conviction springs from the delight. That it is but fiction, will inevitably occur, if not during the perusal, so as to weaken the interest of the tale, yet at the conclusion, when emotion has subsided, and the moral and practical application remains to be made. If any moral feeling be instinctive, it is respect for truth. The child has no sooner learnt the meaning of the word, than he asks is it true, at the close of the narrative which has affected or surprised his young mind. If he finds it to be fiction, it shares the fate of the toy which, having amused him for a second, is no more thought of; but assure him of its truth, and if the moral be not above his reach, he will pluck it, and make it a part of the little system of associations which govern his practice. Whatever good therefore may be effected by fiction, and much it can effect, biography has a great superiority over it from its power of uniting in a much higher degree the two objects of entertainment and instruction.

These are its legitimate objects, instead of which, not unfrequently have been substituted such as it would be difficult to reconcile with the nature of morality. This censure is pronounced not so much upon direct and palpable fabrication, which generally involves its own disgrace and condemnation, as upon false construction, partial representation, and fallacious colouring of facts, which are in the main true, either with a view to some end distinct from utility, or on the mischievous principle of promoting good ends by any means. This is an abuse of biographical writing to which all whose minds are possessed by a sectarian spirit are naturally prone. With them it is a part of religion to maintain the immaculate character of the founders, or principal ornaments of their sect; and to accomplish this, as much ingenuity, and not seldom as little honesty, is displayed as in the eloquence of the bar. By a very common confusion of ideas, the credit of the man, and the truth of that system of opinions which he conceived or supported, are thought to have an indissoluble connection, and the one must at all events be established for the sake of the other. Another abuse, which is indeed akin to the former, and issues from the same source, is, the attempt to make biography subservient to the purposes of political or religious party. With this view a name is chosen which men have been accustomed to venerate; and though the man was born "not for an age," or a sect, but for all mankind, his name is forced into the service of authoritative signature to certain sets of opinion. The violence which is done in such instances to historical truth, is not the whole of the evil; the purpose for which evidence is suborned, and testimony perverted, is condemned by every friend of truth. Few causes have thrown such impediments in the way of enquiry, and, given such stability to error, as the imposition of

names. When authority is opposed to argument, reason must be silent; from that moment it is put out of court; the cause is referred to arbitrary decision; it is to be determined, not by an appeal to the common understanding of mankind, but to the judgment of one whose powers of discrimination might not exceed, and whose means of information probably fell below, those which are possessed by some of his successors. But the most perverted use is made of this kind of history, when it is employed in the service of malice and detraction. Not only is living excellence exposed to the persecution of envy; its malignity has dared to penetrate the sanctuary of the tomb. Long after the curtain has been dropt, the hiss of jealousy or malevolence has been prolonged, and though it may have been drowned at first by general applause, it has found its time to be heard, and that too often with effect. The honest and able biographer holds the balance of departed merit, and feels his office to be one of high responsibility; but when the libeller of the dead places himself on the bench, envy usurps the seat of justice, merit is robbed of its reward, the chambers of the dead are violated, and sacrilege is added to injustice. This abuse of biography is the more dangerous, because the detractor will never want an audience as long as envy and ill-nature are found among mankind; the little-minded will always crowd around him, and it is well if mediocrity does not lend a patient ear to representations, which seem to give it elevation by lowering the standard of comparison. The faults which have been mentioned have little claim upon indulgence; but there are errors incident to biography which are entitled to greater lenity. It is natural that the writer should contract something like a friendship for the subject of his memoirs; and it is no wonder, if, under its influence, he is sometimes tempted to produce too flattering a picture. Not contented to set down nought in malice, he may be bribed by his feelings to suppress what ought to be set down in justice, to throw a veil over failings, and place merit in a light too strong for truth. This is a weakness, which it requires as much apathy as strength of mind to regard with extreme severity, especially if the historian was the associate and friend of the subject of his history: the partiality is amiable, and though our judgment must condemn it, the heart of every good man will plead in palliation of the offence. Still it is a weakness and an error, and one which is not innocent in its effect, whatever it may be in its source: by shaking the authority of the whole relation, it frustrates the design of it, if that design was, as it ought to be, moral improvement. It may also be directly prejudicial to the mind in which right principles of action are not fully established; for it is too much to expect, that the relaxation of rigour which has been admitted in judging the actions of others should have no influence in the judgment we pass upon our own: the apologist of other men is not likely to be a very severe critic upon himself; it is enough that he is not more lenient to his own failings than to theirs; he cannot in reason be required to pronounce a more rigorous sentence when his own cause is determined.

If the historian has his partialities and prejudices, all other men have also theirs. Nations are not free from them any more than individuals, and there are some to which duration, and general suffrage, have given a sort of prescriptive right to govern. It is the duty of the biographer to be upon his guard against the

influence of public prejudice, scarcely less than his own. Though it may be presumed, that the judgment which has been passed upon characters by successive generations, or by a great majority of any single generation, has reason on its side, this must not be laid down as a universal and infallible rule. There is a fashion both in praise and censure, which one age transmits to the next, till it has acquired the sanction of antiquity: it is not easy to account otherwise for the manner in which some names are recorded in history, one being the signal for extravagant panegyric, and another for unqualified censure, though nothing is produced in evidence respecting either, which can justify such warmth of applause or condemnation. The memory, as well as the lives of men, is often attended with a good or ill fortune, that seems to preside over the reputation after death, as it did over the condition in life, with little regard to the true measure of merit or demerit in either. In these instances, the biographer must dare to oppose the stream of opinion; a duty that requires both fortitude and address, whether the opinion respect persons or principles: and as every error has its own antagonist, he who undertakes this labour, is also himself in danger of being enticed by the love of singularity, and of that notice which is attracted by it, to affect new views of characters and actions, widely differing from those which are commonly received, but differing without sufficient evidence and reason. Of this affectation, a late eminent writer, Lord Orford, has been accused; and notwithstanding the ingenuity with which he has added probability to novelty in many of his biographical views, the charge will scarcely be thought to be altogether unfounded.

In taking a survey of the difficulties that press upon biography in particular, the first which presents itself arises from the nature of the authority upon which a principal part of the biography must often rest. National history can refer to national archives, and public documents are the vouchers of public events; but the principal facts in biography, from their nature, will be frequently supported only by private testimony and traditional report. These are authorities which are not always accessible, and when they are so, they are not always the most intelligible or secure. Yet they may be the best, and indeed the only witnesses that can be called in, upon the faith of whose representations new facts are to be produced, false statements to be corrected, some matters of general belief to be controverted, and others to be set in an entirely new light. Hence the biographer will not find it easy to satisfy the public, nor always to assure himself, that his authorities, although the best the case admits, are entitled to unlimited confidence. They form the pedestal of his work, but he cannot conceal from himself that it is sometimes a very tottering pedestal. There is one defect which is inseparable from biography, and must therefore be charged upon the nature of the undertaking, and not upon any unskilfulness in the execution. The causes upon which the principal events of a man's life are suspended are often unknown even to himself. His days have taken their complexion from influences, of which he became sensible only in their remote effects. Impressions were made at a time, and in a manner, that prevented their being marked down; but though no minute of them is preserved, they have left a bias upon the whole conduct of his life, perhaps determined his pursuits, and decided his condition, and his character. We are naturally in-

quisitive respecting the beginning of whatever has become admirable in its progress, and great in its completion. The sources of the stream that inundated and enriched a wide extent of country, could not fail to become an object of eager curiosity; and, in perusing the lives of men who have explored new regions of science, and discovered mines which successive generations have worked without exhausting them of their treasures, we cannot avoid wishing to see the track by which they advanced to the discovery, and to trace it to the very first step that was taken in such a happy direction. The same curiosity in a greater or less degree attends the contemplation of every kind and measure of eminence. We wish to see it in its causes; to inspect the spring, and to compare its force when motion commenced, and before it was communicated to the long chain of instruments by which it acted with the ultimate effect, when the whole machine was brought into play. Such an analysis would not only be gratifying to curiosity, but might lead to reflections of great practical utility, especially in the important business of education. It is seldom, however, that we have the means of looking so narrowly into the mechanism of the lives of the most eminent persons, any more than of those below them. Though the superiority of their powers may have been, and probably was always apparent to the sagacious observer, yet the circumstance, or combination of circumstances, which gave them their direction for the most part, eludes the enquiry even of him whose life was passed under its influence. The story of the fall of the apple, which is said to have directed the penetration of a Newton to the law of gravitation, is well known; and whether it have authenticity or not, it has served to show the eagerness of curiosity to possess such facts. But as every man is a moral agent, and whatever be his powers, deserves to be contemplated principally on account of his moral capacity and relations, the most interesting view that we can take of a man's life, regards it as a process for the formation and development of moral character. It is at the same time the view which it is most difficult to take with exactness, and exhibit with fidelity and entireness. In men of eminence, and biography professes to record the lives of such only, it is not too much to presume, that the grand features of the moral character will be marked with sufficient strength, to make it an easy task to present a faithful portrait. The impression of their virtues or vices will be left in their actions, the best and only certain memorial of what they were, a memorial which every man is able to decipher. But the philosopher and the moralist will wish to look much farther, not only to infer the moral constitution of the mind from the habits and actions of the life, but to see that constitution in its elements, to trace it in its growth, and note the influences under which it was expanded into beauty, or distorted into deformity. He would see, if it were permitted him, the moral habits in the process and act, as it were, of crystallization, and penetrate the subtle and secret action of the mind by which they were fashioned and defined, such as they appear in the life. This insight, however, into the actual impressions and motions of the mind, whilst character was forming, the biographer can scarcely be expected to obtain, since it is seldom that a reflecting man could give a complete and certain history of his own moral formation. He must be content to supply the deficiencies of recollection by conjecture; to account for the changes, or determination of character,

by assigning probable causes, rather than such as are proved by the memory of past consciousness to have actually existed; and if, instead of trusting to recollection, he has made minutes of the feelings, as well as the events of life during the whole of its progress, there is still room for suspecting, that some impressions, which were very influential in producing character, escaped present and immediate observation. These remarks furnish, perhaps, the best apology for the prolix and minute detail of conversations, and occurrences not much distinguished for wisdom and interest, which is found in some biographies. If this minute prolixity be pardonable in any writer, it is in the historian of particular lives, who must sometimes give what is little, and almost puerile, and certainly tiresome, a place in his memoirs, in order to set in its true light what is important, and full of instruction. It is a fault too upon which few are very severe, but critics by profession. The reader, finding himself amused, and interested in the most trifling detail that regards men of extraordinary endowment, easily forgive the fond partiality, the habitual garrulity, and even the communicative vanity of the narrator, when these serve to make him better acquainted with the subject of his tale. Notwithstanding the censure that has been incurred, and in part merited by the biographer of Johnson, his voluminous *Memorabilia* have not found the fewer readers for their particularity and chit-chat prolixity. We are not apt to be violently disgusted with this sort of minuteness, when it is employed on the lives of extraordinary men: it is only when bestowed upon ordinary persons, who did, or possessed nothing when living, which could entitle them to occupy so much space in the annals of the dead, that we turn from it with the impatience that is natural to one who suffers from impertinence.

On comparing the different species of biography, some persons have given an opinion in favour of memoirs, of which the subject is his own historian. Of this number is the author of the *Idler*, who considers the advantage of a perfect knowledge of the facts to be recorded, as more than a balance to the disadvantages inseparable from such an undertaking. In these memoirs, the author cannot deviate from truth through ignorance, or involuntary error. His memory is competent to the task, and his conscience demands that it be faithfully executed, if it be executed at all; and though it is inevitable that his narrative should have the colouring of self-love, every man is sufficiently acquainted with the strength of that principle in his own breast, to make due allowance for its operation. The reader is therefore upon his guard against its delusive representations, and less liable to imposition, than when the narrator pretends to the impartiality of an indifferent observer, or when the bias, if he can be suspected of any, is only such as is impressed by friendship, whose partiality may be judged indifference, when compared with the influence of self-love. There is, however, one kind of biography, which appears to unite in a good degree the advantage which each of the other possesses separately; in which the narrative of the historian is supported, and elucidated by the epistolary correspondence of the subject of his history. Recent examples of this sort are before the public in the lives of the contemporary poets Burns and Cowper.

It would seem needless to remark, that this kind of biography should be appropriated to names of the first eminence on account of its voluminous form, had not

instances occurred in which it is employed on subjects of inferior consideration. But whatever may be the gratification and advantage of possessing such biographies, all who know how to estimate entire confidence between man and man, will enter their protest against an unlicensed, unwarranted, and unfeeling disclosure of what was penned only for private inspection, and in full confidence that it would never be exposed to the public eye. (J. M.)

BIRCH, THOMAS, was born in London in the year 1705. His parents were Quakers; and his father, who was a maker of coffee-mills, intending to instruct him in his own profession, consented with reluctance to indulge his predilection for literary pursuits. He received the elements of grammatical education at Hemel Hempstead, in Hertfordshire, where he afterwards officiated as usher. He sustained the same office in several other public seminaries, and was always remarkably attentive to promote his own improvement by the opportunities of information which they afforded. He never enjoyed the benefit of an university education; but took orders in the church of England, about the year 1728; and married, soon after, the daughter of a Mr Cox, to whom he was acting in the capacity of a curate. His wife died about twelve months after marriage; and Mr Birch, upon that occasion, wrote a copy of verses of considerable merit, which appeared in the Gentleman's Magazine, and are inscribed, with much approbation, in Mrs Rowe's miscellaneous works. Having been recommended to lord chancellor Hardwicke, he was presented by him to the living of Ulting in Essex, A. D. 1732; and in 1734, was appointed domestic chaplain to the unfortunate earl of Kilmarnock. In 1735, he was chosen a member of the Royal Society, under the patronage of sir Hans Sloane; and was soon afterwards admitted also into the society of antiquaries. He passed through a variety of preferments; and the last which he attained, was the rectory of Debden in Essex, A. D. 1761. He received the degree of doctor of divinity from the Mareschal college of Aberdeen; was elected one of the secretaries of the Royal society; became also a trustee of the British museum; and was held in great respect by a number of literary friends; when he was suddenly killed by a fall from his horse, A. D. 1766, in the 61st year of his age. Dr Birch had been very liberal to his relations during his life; but as none of his near kindred survived him, he bequeathed his books and manuscripts to the British museum; and left the remainder of his fortune, about 500*l.* for the purpose of increasing the salaries of the assistant librarians. His literary productions were exceedingly numerous; but chiefly confined to history and biography. He wrote the greater part of the General Dictionary, historical and critical, 10 vols. folio; a variety of lives and memoirs; several historical disquisitions; a number of communications to the Royal Society; a history of its progress and transactions; and left behind him an incredible collection of manuscript extracts and transcripts. Though not ignorant of classical learning, Dr Birch was distinguished chiefly by the variety of his knowledge. He excelled in modern history, particularly in that of his own country; and though by far too minute in his details, is admitted to have been a most judicious compiler. By his habits of early rising and regular application, he was able to accomplish his nu-

merous literary undertakings; and, at the same time, to enjoy a great degree of general intercourse in society. He was of a cheerful and social temper; of simple and unadorned manners; of a very obliging and benevolent disposition; and a friend to civil and religious liberty. See *Biog. Britannica*, and *Biog. Dictionary*. (g)

BIRDS, MIGRATORY. Throughout the whole range of natural history, there is not a more wonderful, nor perhaps a more interesting phenomenon, than that of the migration of birds. We have our summer and our winter birds of passage; but to what countries, some of them, after leaving us, take their flight, has not been yet accurately ascertained. We well know, however, that when the weather is favourable, they are most regular, both in their arrival, and in their departure. The long aerial journeys which they undoubtedly make, while they excite our wonder, must convince us, that this *instinct*, or whatever it may be called, can be nothing but a divine energy, impelling and conducting them, through the trackless regions which they have to explore. The much boasted reason of man is often frail and fallible, but the instinct of brutes seldom forsakes them, and when followed never leads them into error. Strange too, that this sagacity of migration, although in the face of many difficulties and dangers, should always be performed with the utmost alacrity and pleasure. For their subsistence and propagation, Providence has certainly given them this inclination, and power of betaking themselves to such countries and climates, as are best suited, for the time, to yield them proper food, and that are the safest and most convenient for their incubation.

There are a few naturalists, however, and among those principally Daines Barrington, who have disputed, at least doubted, that birds pass any considerable extent of ocean, and are incapable of taking the long flights, which the supporters of what he calls the *hypothesis* of migration maintain.* This assertion, the author of this article, independently of other proofs, can, from his own personal observations, completely confute; for in particular, while on a voyage, during the months of September and October 1799, on board of the Kenyon, bound from New York to Liverpool, in about N. lat. 48°. W. long. 31°, according to governor Pownall's chart of the Atlantic Ocean, he saw several land birds perch upon the rigging of the ship, and among these were two or three hawks, and an owl, which visited them for several successive nights; and he was so fortunate as to catch a species of the *alauda* (lark,) which, though not a bird of passage, shews at least a power of wing equal to a very long flight, being then more than seven hundred from any continent, and not less than four hundred and fifty miles from Corvo, the nearest island from which they could come. Those writers who deny the probability, if not the possibility, of the migration of birds to other countries, and to other climates, find much difficulty to account for their regular disappearance, and to find out into what holes and fastnesses they can hide themselves, when they become invisible here. They generally say, that they creep into hollow trees, into clefts of rocks, into crevices of old buildings, and remain in such places *in a torpid state* during the winter.—Nay, some affirm that swallows retire under the waters of pools, lakes, rivers, and seas; that after this submersion,

* Philosophical Transactions, vol. lxxii.

they revive before the coming spring; and that these birds of summer, with feathers unruffled, and in vigorous case, emerge from their cold, suffocating, and uncomfortable winter retreat. Testimonies, however, of people of supposed veracity, clergymen, justices of peace, &c. have been brought forward to support this most incongruous tale. We have for a long course of years searched through many parts of the kingdom, old towers, decayed buildings, churches, barns, hollow trees, clefts of rocks, and also occasionally used trawl or dr g nets, in ponds, lakes, and rivers, and never were so successful as to find, either in life or in a torpid state, a single reputed bird of passage in any of those places. Another circumstance which these sceptics in migration offer in defence of their system, is to produce some well authenticated proofs of woodcocks being seen, and hatching in England during the summer. That a few instances of this kind have happened, cannot be disputed; but such things are at least unknown to us in Scotland, with one exception; having in the middle of June flushed a wounded woodcock, while traversing a wood in the east corner of Perthshire. As to field-lares, red-wings, and snow-flakes, &c. these gentlemen are much puzzled how to dispose of them, and are therefore in a great degree silent on that head. Barrington, on the improbability of migrations, says, "that it is surprising, if true, that migratory birds are never, during their passage, either heard, or seen by sailors, while navigating our seas." We admit that they are not so often perceived as might be expected; but this we apprehend is owing to the great acuteness of their sight, which keeps them at such a distance, as to be unobserved by vessels, that might otherwise annoy them, on their eager destination. He then rather triumphantly observes, "Besides this, the eastern coast of England, to which birds of passage must necessarily come from the continent, hath many light-houses upon it; they would therefore, in a dark night, immediately make for such an object, and destroy themselves by flying with violence against it, as is well known to every bat fowler." This would imply that they never do so; but he is much mistaken, for woodcocks are frequently known to dash upon Cromer, and other lights upon our eastern coast; and at Cape Henlopen, upon the point of Delaware Bay in North America, there is a lighthouse, the lantern of which is about eight feet square, and from its situation and glare, vast numbers of migratory and other birds are attracted, and often destroyed by flying against it; and to prevent them from breaking the glass, it was found necessary to cover it with a wire lattice of uncommon strength. Here in one morning upwards of a hundred birds of various kinds were found dead.* This evidently shews that birds at times fly during the night; a fact denied by this naturalist, and upon which he founds one of his leading arguments against migration.

Immediately after our summer visitants take their departure for the more temperate climates of the south, those of winter, to avoid the more cold and icy regions of the north, arrive in Britain. It is somewhat surprising that birds of passage, although it may seem much against the facility of their migration, and which is analogous to the swimming of fish against the stream, al-

ways delight in steering their course against the wind, if not too strong for their flight. Those of summer return to hatch on the same grounds and spots on which they themselves were hatched, while the parents frequently reoccupy their former nests, and those of winter invariably take possession of the same fields and woods which they left previous to the commencement of our spring. Other particulars will come to be mentioned, when we treat separately, of our most noted birds of passage; and then we shall also produce a few specimens of the opinions and testimonies of both the writers, for and against submersion and migration.

The most early harbinger of spring, among our birds of passage, is the *Swallow*. He appears in April before the *Cuckoo*. Upon their arrival, the swallows first attract our notice, when skimming along some village green, or adjacent pool; they then seem in good case, their feathers unruffled, and in no respect the worse of a long flight. Of this genus, we have four species that visit this island. The chimney swallow (*hirundo rustica*), the house martin (*hirundo urbeica*), the sand martin (*hirundo riparia*), and the swift or black martin (*hirundo apus*), which does not appear till May. In this order they arrive, one after another, the chimney swallow preceding the others by several days. This is the bird that has given rise to so much controversy concerning its winter retreat; some naturalists, however, take in the whole tribe, indefinitely, in this dispute. Olaus Magnus, Etmuller, Biberg, Forster, Barrington, and even Linnæus, seem to favour the opinion of the submersion, and after resuscitation of the swallow.† We shall quote a few of the most striking, from the many authorities given in support of this wild and supposed process in natural history.

"Mr Peter Brown, a Norwegian, and ingenious painter, informs me, that, from the age of six to seventeen, whilst he was at school near Sheen, N. lat 59°, he with his companions hath constantly found swallows in numbers *torpid* under the ice, which covered bogs, and that they have often revived, upon being brought in a warm room."

"Mr Stephens, A. S. S. informs me, that when he was fourteen years of age, a pond of his father's (who was vicar of Shrivenham in Berkshire) was cleaned during the month of February; that he picked up himself a cluster of three or four swallows (or martins,) which were caked together in the mud; that the birds were carried into the kitchen, on which they soon flew about the room in the presence of his father, mother, and others, particularly the reverend Dr Pye."‡

"Dr Wallerius, the celebrated Swedish chemist, wrote in 1748, Sept. the 6th. O. S. to the late Mr Klein, secretary to the city of Dantzick, "That he has seen more than once swallows assembling on a reed, till they were all immersed, and went to the bottom, this being preceded by a dirge of a quarter of an hour's length. He attests likewise, that he had seen a swallow, caught during winter, out of a lake, with a net, drawn, as is common in northern countries, under the ice; this bird was brought into a warm room, revived, fluttered about and soon after died."

"I can reckon myself (Forster) among the eye wit-

|| We suppose this must have been what that most marvellous natural historian Pontoppidan calls the swallow's song, which every one knows they chant before sinking under water. *Nat. Hist. of Norway*.

nesses of this paradoxon of natural history. In the year 1735, being a little boy, I saw several swallows, brought in winter, by fisherman from the river Vistula, to my father's house, where two of them were brought into a warm room, revived, and flew about. I saw them several times settling on the warm stove (which the northern nations have in their rooms,) and I recollect well, that the same forenoon they died, and I had them when dead in my hand.*

In the same style, innumerable affidavits from North America, and other parts of the world, have found their way, into our newspapers, journals, and magazines. The Statistical Account of Scotland furnishes us with a specimen, somewhat more circumstantial, but of the same kind with the foregoing, and from being nearer home we shall with it close our proofs for this submerging system.† "We have no uncommon migratory birds; and it is doubtful whether all birds, usually reckoned of this class, do really belong to it. The ground of this doubt well appears, from the following observations respecting the swallow. Owing to a hint given to me by a neighbour, I have been for some seasons pretty attentive to the first appearance of this bird, but not accurate enough to mark the dates, till last spring, when on the 2d of May 1793, I saw them for the first time, pretty early in the morning, in considerable numbers on the loch (about eighteen yards from the bottom of the garden,) from which they seemed to be just then in the process of emerging, though, as there was some rippling in the water, it was difficult to discern the breaking of the surface, but the observer is positive, they just then arose from the lake, and therefore must have lodged or lain somehow at the bottom, since the time of their disappearing last year. The weather all day continued as it began in the morning, moderate with an easy breeze from S. W. and the swallows sonetimes in bodies, sometimes in detachments, enjoyed themselves, in skimming along the surface, or soaring aloft in the air, or fluttering about the shores, but went very little way off the water till evening, when they collected over the lake, and disappeared within observation. With anxious expectation they were looked for next morning, and all day through, but no appearance of them, nor for several days following; and therefore there can be no doubt of their descending into their lodgings at the bottom; having from that day's experiment, felt or judged the air not sufficiently encouraging for them to live in. Nor were they seen till the 11th of May, when they were again observed in the process of emerging from the lake, and continued playing their gambols, and fluttering about the shores of it, until evening, when they disappeared as formerly, and were seen no more till the evening of the 21st of May, when the manner of their disappearing was exactly the same as before mentioned. The last experiment succeeded; they felt, it should seem, the temperature of the air encouraging, and in a few days began to prepare their summer dwellings."

It is an unpleasant task to express our doubts, respecting the accuracy and truth of these seemingly well attested statements; our readers, however, can give such degree of credit to them as they think they may upon the whole deserve. For our part, we can hold

them in no other light than we do the certificates obtained and annexed to the advertising bills of quacks and mountebanks, enumerating the various cases of persons restored to health, by their never-failing medicines. We at the same time admit, that natural history ought not to be studied from conjectures and opinions, but from a history and collection of well known facts. But here, where the fences of probability, nay of the laws of nature, are broken down, to give way for a wild hypothesis, and groundless system, we must pause, and have at last recourse to unbelief. But we shall now proceed to offer our reasons, for doubting the correctness of the preceding narratives. The specific levity of a swallow must prevent it from being able to descend to the bottom of a rapid river. No bird could continue for six months under water, without suffocation or corruption. That celebrated anatomist and naturalist, the late John Hunter, tells us, "That he had dissected many swallows, but found nothing in them different from other birds, as to the organs of respiration," and consequently draws this conclusion, "that they could not remain for any time under water, without being drowned." It is an incontestible fact, that swallows do not moult in this country, and if they hibernate under water, it is simply impossible that they can undergo that operation, or at least acquire new feathers there. We may therefore ask, where do they moult? The ingenious and inquisitive Reaumur says, that he was often promised, from several of his correspondents, ocular demonstration of bundles of swallows to be found under the ice, or that might at any time be discovered torpid in old buildings, &c. but that none of these gentlemen ever kept their words with him. We have also holy writ to confirm us in the belief of the migration of the swallow, "yea the stork in the heaven knoweth her appointed times, and the turtle, and the crane, and the swallow, observe the time of their coming." (Jeremiah chap. viii. v. 7.) From all these considerations, we infer, that the whole of the swallow genus are birds of passage, and that they do not remain torpid with us during the winter, either above or under water, or in any state whatever. That some in holes and bores may be found dead, or others drowned, we shall not dispute; nor shall we pretend absolutely to determine, to what countries they go after leaving us. We are, however, rather inclined to imagine, with Willoughby and Buffon, that they winter in Africa; an opinion which is much strengthened by the following observations of Adanson when at Senegal: "(February) The hut where I lodged was large and commodious, but as dark as a subterraneous cavern, even at noon day, because it had no other opening but a door pierced at each end. Here I must observe, that a great number of our *European swallows* resorted hither every evening, and passed the night upon the rafters; for, as I have elsewhere mentioned, they do not build nests in this country, but only come to spend the winter." Voyage to Senegal.

The writer of this article has also to mention another circumstance, which entirely convinced him that the whole of the swallow genus, previous to the setting in of winter, migrate from cold to warm countries.

On the 11th day of October 1791, when on board the ship *Pigou* from London, bound for Philadelphia, be-

* Forster's notes to Kalm's Travels, vol. ii. p. 6--8.

† Account of the Parish of Rescobie, Forfarshire, by the Rev. Thomas Wright.

tween the capes of May and Henlopen, he observed immense flocks of swallows,* flying towards the south. Next day when he came within the Delaware, myriads also appeared, all stretching and steering their course in the same direction, which was down the river. Pennant, a naturalist whom we must always mention with veneration, although he sneers at the idea of the submersion of the swallow, yet yields, in some degree, to the opinion, that the latter hatches, or broods remain in this country and become torpid during winter; but he has brought forward no satisfactory evidence to establish this point. The swift disappears about the middle of August, the chimney and house swallows from the 10th to the 15th of October, and the sand martin soon after them.

The bird, that in spring (April) immediately follows the chimney swallow and house martin, is the *cuckoo*, (*cuculus canorus*,) the only species of the genus *cuculus* that we have in Britain. His monotonous and short call, although somewhat unmusical, gives always delight, as it is the never-failing indication of approaching summer. The cuckoo often calls when flying, is restless, and seldom sits, or continues its notes long on one tree. The prevailing opinion is, that it neither hatches nor rears its own young. But as we are, in general, unbelievers in most of the supposed anomalies of nature, we shall offer our doubts respecting the truth of this assertion. The opinion respecting this unnatural act of indifference of the cuckoo towards its own offspring, may be traced so far back as the days of Aristotle, who has written on the subject, and who was afterwards followed by Pliny. These naturalists differ a little in their accounts; the first averring, that the cuckoo destroys all the eggs in the hedge sparrow's nest, and then deposits her own single one; while the last author says, that the hedge sparrow, notwithstanding the disparity of size, hatches the additional egg, with the whole of her own, which remain untouched. The general study of natural history, has enabled us to judge of the degree of credit, that should be given to the many idle stories, which formerly disgraced her volumes; such as the ostrich laying her eggs in the hot sands of Africa, and the sun hatching them without any regard on the part of the parent. Of the fretful porcupine shooting his quills against those who assailed or annoyed him, and with many others of the same kind. But late travellers have convinced us of the falsity of these and such reports. We are also apt to think, that this popular story respecting the cuckoo, will soon, like these, pass away as a mere vulgar error. We never yet, after much pains and search, could find a cuckoo's egg, either in the nests of wood pigeons, hedge sparrows, larks, wagtails, or yellow hammers. To make all these birds stand as the foster dams to the cuckoo, is surely a most glaring absurdity. Some of them are not insectivorous, which all cuckoos are; and we can hardly imagine, that they would change their food and habits of life, and become, contrary to nature, the affectionate guardians of such unaccountable orphans. Wood pigeons and yellow hammers feed upon grains and seeds; cuckoos upon caterpillars, meal worms, maggots, dragon flies, &c. Birds, too, that are not domesticated, would hardly submit to have their own eggs thrown out, and to have such a huge one placed in their stead, without forsaking their nest. Mr John Hunter, whom we have formerly

mentioned, dissected many cuckoos, and found them well fitted and formed for incubation as any of the birds that are said to hatch them. Indeed, we have frequently made inquiries about this popular belief, of the cuckoo not hatching her own eggs, nor of rearing her own young, but we never were able to get any well authenticated accounts of such an unnatural abandonment of parental care. We therefore are rather inclined to be of opinion, that, upon a close investigation, the cuckoo will be found to build its own nest, to lay more eggs than one, and to bring them into life from its own incubation. Many more fabulous stories are told about this silly bird, of its being discovered in stacks of wheat, with its feathers pulled off, and of its lying hid in hollow trees, &c. but all such tales are void of truth, for the cuckoo undoubtedly migrates early in the season, in order to pass the winter in some more temperate climate than that of Britain.

The rail, corn crake, or daker hen, (*rallus crex*) arrives in Scotland about the middle of May, and his note is heard, whenever the meadow, sown grass, or corn fields, are so long as to cover or conceal him when running. Its call is pleasant, from the circumstance of its ushering in our summer. We name them *crakes*, from the sound which they emit resembling crake, crake, crake. They run along the ground with surprising swiftness, and their cry may be heard in every corner of an inclosure, of 20 or 30 acres, in a very few minutes. Although they are unquestionably birds of passage, they are seldom seen either going from, or returning to this country. There are great numbers of them in Scotland, Ireland, Anglesea, and some other parts of Wales; but they are rather scarce throughout England, except in the northern counties. They generally lay from eight to twelve eggs, and the young crakes run as soon as they burst the shell; but the mower's scythe is frequently fatal to them, by sweeping away the nest before this period arrives. The partridge fowler falls in with them among the turnips and the late standing corns, in which they take shelter when the other fields become bare. They frequently foil the pointers, by making sudden stops and squats, by which means they often overshoot them; but a known dog is commonly aware of this trick; however, they have always much difficulty in springing them, and are obliged sometimes to run hard to force them on the wing; they fly slowly, and are easily brought down, even by an inexperienced fowler. They leave us whenever the fields are clear of the growing corns.

It has been said, that wherever rails are plentiful, there also quails abound, (*tetrao colturnix*). This is an assertion which we know to be ill founded, as the quail is a scarce bird with us, although crakes are numerous. Indeed, they seem to delight more in haunting warm than cold climates, for in Italy, and other parts of the south, a hundred may be found for one that we have in our northern kingdom. We have seen a few heaves in the county of Haddington, and two or three single birds in Fife, but in no other places of Scotland. Daniel, in his *Rural Sports*, tells us, "that the quail seems to spread entirely throughout the old world, but does not inhabit the new." From what source he derives this information we cannot say, but he is certainly much mistaken, as we have shot many hundreds in America, and have seen thousands in a day brought both to the mar-

* *Hirundo cauda aculeata*, *Americana*. Catesby.

kets of Philadelphia and New York. They are, it is true, on account of their great size in comparison with the European quail,* (weighing about eight ounces,) called by some Dutchmen and old English inhabitants partridges, but they have all the distinguishing marks of *the real colturnus*, and also the peculiar note of whit, whit, whit, which quails often repeat when running, flying, or calling to their young. If pressed by dogs, they frequently perch upon trees, which partridges seldom or never do. They are the only species of the *tetrao* genus that migrate, and this characterises them in America, as well as in every other part of the world. As grouse and partridges are the principal birds of sport with our British fowlers, so are quails with those of America. In the state of New York, one person, with a dog and a gun, will often kill six or seven brace before noon. In America, they frequent the wheat and maize stubbles during the day, and retire generally to the woodlands to pass the night. Instead of the quail pipe and net, the farmers there generally use traps, or gins; these they place in the tracks which those birds make in their way from the woods to the cornfields. It is upon the first appearance of dawn that they traverse this ground; and they are then taken in great numbers, and are brought to market by the country people along with the rest of their poultry. The time of the arrival of the few which we have in Scotland has not been well ascertained, but they depart early in October.

The goat-sucker, (*caprimulgus Europæus*.) called in several places of England the goat-milker, fern and churn owl, appears in Scotland about the first of June. It derives its name from the once received belief of its sucking the teats of the goat. This opinion was, so far as we know, first patronised by Aristotle, although perhaps held as a truth long before his time. But the idea is now, by every rational naturalist, completely exploded. When twilight sets in, the goat-sucker is commonly discovered sitting upon the stump or bough of a leafless tree, or fluttering amidst the dust of some beaten road. It emits a singular vibrating sound, something (as has been observed) like the noise of a large woollen spinning wheel; and when pursuing or addressing its mate, gives a shrill quick cry, which is supposed to be the language of love. Kalm and Linnæus seem to confound this bird with the *caprimulgus minor Americanus* of *Catesby*, both making them only varieties, and not a distinct species, which they undoubtedly are. Kalm says, "their shape, colour, size, and other qualities, make it difficult to distinguish them from each other." In shape, as being birds of the same genus, they certainly have some resemblance, and they are both migratory. But they differ in every other thing; the plumage of the American is by many shades darker, more spotted, and also in respect of size somewhat larger, than the European goat-sucker. What particularly distinguishes the first, is its peculiar call, *whiff-poor-will*, from which the Anglo-Americans give it that name. They fly during the day, which none of our species ever do. About the beginning of September the European goat-sucker disappears in Scotland.

The foregoing are our principal migratory summer land birds. We now come to the most noted, and we believe the only summer water fowl, excepting perhaps the puffin, which we can with absolute certain-

ty determine to be migratory. The gannet, solan, or soland goose, (*pelicanus Bassanus*). We apprehend they breed in no other part of the world but Scotland, and there only in the rocky and steep isles of the Bass, Ailsa, and St Kilda. Pennant says, on the authority of Dr Pocock, bishop of Meath, that a few hatch on the Skelig isles, off the coast of Kerry, in Ireland. This we rather doubt, although we shall neither offer to affirm nor contradict it. Smith in his history of Kerry, seems to leave us in the dark respecting this matter. Gesner, Aldrovandus, and Jonston, call it *anser Bassanus sive Scoticus*. The chops of the solan goose are notched, or jagged like a saw. The plumage of the old birds is of a dirty white, except the greater quill feathers, which are black; but the whole body remains of a dark brown colour, somewhat spotted, until the second year of their age. They have a pouch under the chin, in which they can carry several sprats, pilchards, or herrings; with these they feed their young, who draw them out of this bag in a most artful manner. Their legs and toes are black, edged with a stripe of beautiful green. Their wings are so very long, that when they light on the ground they have much difficulty in rising again. They lay or at least hatch, but one egg. They appear in the firth of Forth in the month of March, and depart in the end of September. It has been said, however, that since the herrings of late years have continued there in winter, many of the gannets bred upon the Bass never leave it. When they quit our firth, they fly along the coast of England, remain some time in the channel, especially about Cornwall, where they find immense shoals of pilchards; and, when these become scarce, they then betake themselves farther to the south, and have been observed in December fishing for sardines, (a species of the genus *clupea*.) off the Berlingas, and the rock of Lisbon. We have seen several of the old birds (these are such as have changed their colour to white) during winter, in America. Indeed, we have eaten them there, and at that time had no doubts of their being emigrants from Scotland. The young gannets, while scarcely fledged, are brought from the Bass to the Edinburgh market. They for a very long tract of years used to be sold at 1s. 8d. but the price is now somewhat advanced, generally about 2s. each. In these isles they have a very dangerous method of taking gannets. Before they are able to fly, a person is let down from the top of the perpendicular rocks, hanging upon a long rope, which is tied about his waist, and, while thus suspended in the midway air, he is lowered, or drawn higher, from cleft to cleft, according to the management of those who hold it from above, and upon whom his sole dependence of preservation is placed. On the rough surge beneath a boat attends, into which, after killing them, he drops the birds from the nests above; he sometimes, however, fixes them to a string, or puts them into a bag, which he has slung over his shoulders for that purpose.

Of our migratory land birds that come to pass the winter with us, the first is the red wing, swine pipe, wind or wood thrush, (*turdus iliacus*). Its whole appearance is similar to that of our common song thrush, but only smaller, and reddish under the wings. In its own country, Sweden, where it breeds, it sings most delightfully, from the top of its favorite tree the maple. It is almost mute while with us, and is a solitary bird,

* This is a rare instance, in opposition to the hypothesis of Buffon, "That animals common both to the old and new world are smaller in the latter."

Keeping at the bottom of hedges, or in bushes, excepting upon its arrival and departure, when they congregate. They are commonly seen a few days before the fieldfare, or juniper thrush, (*turdus pilaris*), who continue in large flocks during their residence here; they frequently perch upon trees in the day time, but always roost upon the ground during the night. These two last-mentioned birds are also migratory in Italy, and other parts of the south of Europe; they were the turdi of the Romans, which they fed with so much care and attention, in their aviaries. When they became fat, they were highly esteemed by the epicures of these days.

The woodcock (*scotophax rusticola*) appears generally with the Michaelmas moon, which favours its flight across the German or northern sea. When they land on our coast, they seem stupid and worn out with fatigue. This is somewhat surprising, as their passage is so much shorter than that of those birds from the southern climes, who are always fresh and vigorous when they first make their appearance in this country. Mr Pennant says, that woodcocks take the advantage of a mist, or of a thick night, in accomplishing their passage. We, on the contrary, have constantly observed more numerous arrivals when there were clear moonlight nights, than in dark and foggy weather. We also think, that their flight depends more on that luminary than on the wind; that is to say, if it does not blow very hard while the moon shines. Their departure from the northern parts of Europe, Norway, Sweden, &c. commences about the first week of October, and detached birds, as they seldom congregate, continue to migrate until the end of November. When they first arrive here they drop upon heaths, and among furze and other bushes, and, after having settled and rested for two or three days, betake themselves to coppice or wet woods; there and about the adjacent springs, they continue for the winter, unless often flushed, and driven off by men and dogs. Woodcock shooting is a favorite sport with our fowlers. The vast numbers that are sent, during the winter season by stage coaches, from the provincial towns of England to the all-devouring capital are truly astonishing. The American woodcock is in all respects the same as the European, only of less size. They return from Britain to their native haunts in February and the beginning of March.

The snow bunting, better known in Scotland by the name of snow flake, or flight, (*emberiza nivalis*). It is late in the season before these birds shew themselves here; they are commonly the heralds of hard and snowy weather, and sometimes, if fatigued, fall on vessels while on their passage across the Pentland Firth. We apprehend they do not quit Lapland, Norway, or the northern parts of America, until, by the heavy storms of these rigid climates, they are forced to seek a comparatively milder temperature. It is said, that a few breed in the mountains of Scotland, but we never saw, nor indeed heard of, any person who discovered during summer a nest or even a straggling bird of that species. They are not often observed in England, as their excursions to the south generally terminate in the Cheviot hills. They assemble in great flocks, are sudden in their arrival, and equally so in their departure.

The Bohemian or waxen chattering, or the silk tail, (*ampholis garrulus*) is a singularly beautiful bird. It is bigger than a sky lark, the length, from the tip of the tail, being nine, and the breadth, when the wings are extended twelve inches. The bill is of a deep black; on

its head there is a crest. The breast is chestnut, the belly ash, the back bay, the rump of a dun colour. The outward wing feathers black and spotted. Upon the tips of the seven small quills are horny appendages, of a fine vermilion, somewhat resembling sealing wax. They are gregarious, and visit us but with a short stay, and that only in two or three years, and not annually, as alleged by Pennant and the late Dr Ramsay. We have at different times seen small flocks of them about Collington, a village to the west of Edinburgh, where several have been shot, and afterwards preserved. They come always in February, remain a few days, and then return to their native country, Bohemia.

The hoopoe (*uphupa uphus*). Not breeding in Scotland we shall set it down as a winter bird of passage. They come from Italy and Germany, are desultory in their motions, and observe no stated times in their appearance; indeed few are to be met with in this country at any season. We have seen only two here, one which the late Mr Weir found near Edinburgh, and had afterwards preserved in his museum, and another which was sent us from the east nook of Fife, by a gentleman who had shot it there. The hoopoe is near the size of the lapwing, but does not weigh one half so much. The head is adorned with a fine crest, of two inches high, reaching from the bill to the nape of the neck; both the plumage and the figure are truly elegant, and many take it to be one of the most beautiful birds in Europe. Its appearance used formerly to be reckoned by the vulgar as a presage of some direful calamity. A few of the *anas* and *mergus* genera, who breed during summer in the retired lakes and swamps of Lapland, Norway and Finland, arrive here early in the winter.

Before leaving this article, we have to regret, that such a *desideratum* as a thorough knowledge of the migration of birds should have been so little studied, and so long neglected. Indeed, until it is more sought for in the fields than in the closet, any farther insight into this divine impulse cannot well be expected. What excellent opportunities have our clergymen, sportsmen, and travellers, to inform themselves and the world of the curious particulars, which attend this wonderful subject! They might easily, by taking observations, which are so often within their reach, soon remove the various doubts and uncertainties that still hang upon this most interesting branch of our natural history. (A. D.

BIRD-CATCHING, denotes the art of taking birds or wild fowl; and is performed in various ways, according to the season of the year, or the species of bird intended to be caught.

If the flame of sulphur be held under the trees, on which birds are observed to perch during the night, they soon become suffocated and fall down in a state of insensibility: In this manner pheasants are frequently caught.

If a portion of wheat, or any other grain, be steeped in a mixture of wine lees and hemlock juice, and then scattered in those places where birds are known to resort, they will speedily be inebriated by eating it, and drop down upon the ground, or become unable to escape.

When the ground is covered with snow, choose a spot within 20 or 30 yards of a window, door, or any other shelter, by which you may be concealed from the birds; and clear away the snow from a space about six or seven feet square. In the middle of this space place a wooden table or board; fasten to its sides several pieces of pipe staves, about six inches long and one broad.

in such a manner that it may easily turn upon the nails; and under the four ends, which are not nailed, put four pieces of tile or slate, that they may not penetrate the ground, so as that the table may fall down upon the slightest jog. Make a small notch in the end of the table, in order to put into it the end staff, which should be seven inches long and one broad, and let the other end rest upon a piece of slate or tile. Arrange the whole in such a manner, that the board would be ready to fall towards the place where you stand, if it were not supported by the end staff; and to the middle of this staff let one end of a small cord be fastened, while the other end is conveyed to your station. To make the board fall more readily, a little earth, or any other material least likely to frighten the birds, may be laid upon it; the whole is then to be covered with straw, and some grain scattered underneath and round about the board. When the birds perceive the ground free from snow and covered with straw, they will readily fly to pick up the corn round the board, and will gradually proceed to that which lies under it; the cord is then to be pulled, and the stick being thus drawn out, the board will fall down and secure the birds underneath.

The smaller kinds of birds are frequently taken with bird-lime, which is one of the most eligible modes in frost or snow, when all sorts of small birds assemble in flocks, and which may be used in various ways. Put the bird-lime into an earthen dish, with the addition of one ounce of fresh lard to every quarter of a pound, and melt the whole gently over the fire. Take a quantity of wheat ears, with a foot of the straw attached to each, and having warmed the lime that it may spread the thinner, lime about six inches of the straw from the bottom of the ears. Scatter a little chaff and threshed ears over a compass of 20 yards; stick the limed straws into the ground with the ears inclining downwards, or even touching the surface; traverse the adjoining places, in order to disturb the birds, and make them fly towards the snare; and by pecking at the ears of corn, they will become so entangled with the limed straws as to be easily taken with the hand. The lime may also be applied to cords, rods, and twigs, especially when it is intended to entangle the larger birds, such as snipes and field-fares; and for this purpose the following mode may be adopted. Take the main branch of any bushy tree with long straight and smooth twigs, such as the willow or birch; clear the twigs from every notch and prickly; lime the branches to within four fingers of the bottom, leaving the main bough, from which the others rise, untouched with the composition; and then place the bush where the birds resort. For small birds, two or three hundred single twigs, about the thickness of a rush, and three inches in length, may be stuck in sheaves of flax and corn. In hot and dry weather the twigs may be placed around the rivulets, ditches, and pools, to which the birds come for drink; covering the waters at the same time with brushwood, so that they can have no access to quench their thirst, except at the spot where the twigs are fixed. For this purpose, the rods or twigs should be about a foot in length, limed to within two inches of the thickest end, which is stuck into the bank in such a manner, as that they may lie within two fingers breadth of the ground; and as the birds do not alight at once upon the place where they are to drink, but gradually descend from the higher trees to the lower, thence to the bushes, and lastly to the bank, it is usual to fix a few branches about a fathom from the water;

in a sloping direction, with a few lime twigs fastened upon them, on which the birds will as frequently be caught as on those which are placed nearer to the water. The best time for this sport is from ten to eleven in the forenoon, from two to three in the afternoon, and about an hour before sun-set, when the birds come to the watering places in flocks before they retire to roost. Spallanzani describes, in the 6th volume of his Travels, the following mode of taking swallows by means of bird-lime, (at the time when they are building their nests,) with which he amused himself in his younger years. He took a slip of birch wood about an inch in length, covered it with bird-lime, and fastened it across a light feather. He then ascended the roof of the out-houses, around which the swallows were flying, blew the feather to a little distance with his mouth, and as it was carried away by the wind, or fell slowly downwards, it was seized by the birds, and entangling their wings by the bird-lime, made them fall suddenly to the ground. Various means are employed to collect the birds together, and draw them towards the spot where the lime twigs are fixed. They may be attracted by imitating their notes with the mouth, or a bird call; by living bats or owls, which will be followed and gazed at by the other birds; and even by having their skins well stuffed, or their figures carved and painted in wood; by a bird of the same kind with those which are to be caught placed in a cage upon forked sticks, a few inches from the ground, at a fathom's distance from the twigs; or by fastening some of the birds that have been taken to a packthread extended between two sticks, allowing them so much freedom that they can stand easily on the ground, and when the string is pulled can fly up to a small height, in order to attract those which are hovering in the air.

Birds are taken also by various kinds of traps, which are frequently formed in a very simple manner, of nooses made of hair, and which are placed in different ways for different kinds of birds. The wheat-ears are so extremely timid, that they take shelter under a stone, or creep into holes whenever the sun is obscured by a cloud; and, by digging a number of small holes in the ground, in each of which is placed a noose of hair, they are taken in the open downs in great numbers. Wood-cocks and snipes are caught in a similar manner, by placing the nooses along their paths, in marshy and moist grounds. Larks and other small birds may be taken in the same way, when the ground is covered with snow, by stretching along the surface 100 or 200 yards of packthread, pegging it down at the distance of every 20 yards, and fastening, at every six inches, a noose of double horse hair. Some white oats are scattered along the line among the nooses, in order to entice the birds; and when three or four are taken, they must be removed from the noose, lest the others should be debarred from approaching.

One of the most successful modes of bird-catching is by the net, which is chiefly employed during the night, and which requires several other accompaniments. Take, for instance, two light and straight poles, ten or twelve feet long; tie two corners of the net to the smaller ends of these poles, and fasten the other two corners as far as they can be stretched towards the thicker part, connecting the sides of the net along the poles with a little packthread. Search for a bush or thicket to which the birds are likely to have retired; unfold the net, and pitch it exactly to the height of the bush, between the wind and the birds, as they always roost with their

breasts towards the wind. Let a person, with a lantern or lighted torch, stand behind the middle of the net, while another beats the bushes on the opposite side, driving them towards the light, when they will readily fly to the quarter where the torch is held, and fall into the net. This method succeeds best in woods, where holly bushes grow under the trees, and when the weather is cold and dark. In open countries a trammel-net may be used, which is generally about thirty-six yards in length, and six in breadth, the lower end of which is plumbed to make it lie close, while the upper end is kept suspended at the two corners, and is thus dragged along the ground at about a yard in height. At each end lights must be carried, and persons stationed with long poles to raise up the birds as they proceed, and to take them as they ascend under the nets. Along with the nets and lights, a bell is frequently employed in open countries and stubble fields, from the middle of October to the end of March. At night, when the air is mild, take a low bell of a deep and hollow sound, and of such a size as to be conveniently carried in one hand; and provide a lantern or a square box, lined with tin, and open at one side, into which two or three large lights are to be placed. Fix the box to the breast, carry the bell in the left hand, and with the right hold a hand-net, about two feet broad and three long; or the light may be held in the hand, with the arm extended forward, while the bell is tied to the girdle, and hangs down upon the knees, by the motion of which it is made to sound. A companion may walk on each side, provided with a hand-net three or four feet square, but keeping a little behind, that he may not be within the reflection of the light. The sound of the bell makes the birds lie close, while the light also tends to overpower them; so that the net may easily be spread over them, as they are seen lying on the ground. Birds are also taken with nets during the day, especially in those seasons of the year when they change their situation; in the month of October, for instance, when the wild birds begin to fly, and in March when the smaller kinds assemble for pairing. They are chiefly on the wing from day-break to noon, and always fly against the wind. The bird-catchers, therefore, lay their nets towards that point to which the wind blows. The nets employed in this way are generally twelve yards and a half long, and two and a half wide; and are spread on the ground parallel to each other in such a manner as to meet when turned over. They are provided with lines fastened in such a way, that, by a sudden pull, the bird-catcher is able to draw them over the birds, that may have alighted in the space between those parallel sides. In order to entice the wild birds to alight among the nets, *call-birds* are employed, of which there must be one or two of each of the different kinds which are expected to be caught, such as linnets, goldfinches, greenfinches, woodlarks, red-polls, yellow hammers, titlarks, aberdavines, and bullfinches. Besides the *call-birds*, there are others denominated *flur-birds*, which are placed upon a moveable perch within the net, called a *flur*, and which can be raised or depressed at pleasure; and these are secured to the *flur* by means of a brace or bandage of slender silk string fastened round the body of the bird. The *call-birds* are disposed, at proper intervals, in cages, at a little distance from the nets; and as soon as they see or hear the approach of the wild birds, which they perceive long before it can be observed by the bird-catchers, they announce the intelligence, from cage to cage, with the greatest appearance of joy; and they pro-

ceeded to invite them to alight, by a succession of notes, or short *jerk*s, as they are termed by the bird-catchers, which may often be heard at a considerable distance. The moment that this call is heard by the wild birds, they stop their flight, and descend towards the nets; and so great is the ascendancy and fascination of the *call-birds*, that they can induce the others to return repeatedly to the nets, till every bird in the flock be caught.—Nightingales are taken with small trap-nets, without the aid of *call-birds*. These nets are not much larger than a cabbage-net; are surrounded at the bottom with an iron ring; and are baited with a meal-worm from the baker's shop.—In fine sunny weather, sky-larks are allured within reach of the clap-nets, by means of small bits of looking-glass fixed in a piece of wood in the middle of the nets, and put into a quick whirling motion, by a string in the hand of the bird-catcher. Grouse and partridge may be taken in the evening, by observing where they alight, and drawing a net over them; or, in the day-time, by employing a steady dog to point at them; and while their attention is fixed upon the animal, a large net, drawn by one person at each end, may easily be passed over them.

In the first volume of Vaillant's *Travels in Africa*, is described the following ingenious method of procuring birds alive, and without injuring their plumage. He put into his fusce a larger or smaller quantity of powder, as circumstances required. Above the powder he placed the end of a candle, ramming it well down; and then filled the barrel with water. With the musket loaded, in this manner he fired at the birds which he wished to procure; and they were so stunned and wetted by the water, as to be brought to the ground, and easily picked up before they could injure their feathers by struggling, or recover themselves to fly away.

Jays, blackbirds, and magpies, but particularly the former, may be taken in the following ludicrous manner: Take a tame jay into the woods where others of that species are known to resort, lay the bird upon the ground on his back, and, with two pegs, pin down his wings in such a manner, as to keep him fast without hurting him. Retire to your station, and watch the issue. The cries of the jay, while struggling for liberty, will attract all of his own species in the neighbourhood; and, as they are fluttering and leaping around him, he will not fail, in his desperation, to seize with his bill and claws any one that may come within his reach, and to hold it fast till you approach to seize the prey. The jays will return repeatedly to the spot; and thus, with the same bird, many captures may be successively secured.

In the Orkney Isles, eggs and young birds are collected by the inhabitants, in a most daring and hazardous manner. They climb up rocky precipices, more than 50 fathoms above the sea, where the shelves or ledges are scarcely broad enough for the birds to rest, or to form their nests; and, passing from one ledge to another, collect the eggs and birds, and descend again with the greatest ease and indifference. In most cases, however, they make the attempt from above; and are let down by a rope frequently made of straw or hogs bristles, which are less apt than those made of hemp, to be cut by the sharpness of the rocks. A single assistant lets down his companion in this manner, and shifts the rope from place to place, according to the signals which he receives. His associate, in the mean time, "hovering in mid air," springs from the face of the rocks by the aid of a staff.

to avoid the projecting cliffs, and thus conveys himself along from place to place, rifling the nests as he proceeds.

A similar method is practised in the Feroe Islands, where the cliffs are in many places 200 fathoms high. The fowlers provide themselves with a rope about 100 fathoms in length, which is fastened round the waist of one of their number, who is then lowered down the precipice by six associates; and a piece of board is laid on the margin of the rock to prevent the rope from being cut by the friction. The adventurer is, at the same time, furnished with a small line, by which he gives signals for his being raised, lowered, or moved from place to place; and with a strong thick cap to defend his head from the stones, which are frequently displaced by the shifting of the rope. With inconceivable dexterity he pushes himself with his feet several fathoms from the front of the precipice, surveys the haunts of the birds, and darts into the openings where he has discovered their nests. When these recesses are deep, he disengages himself from the rope, which he fastens to a stone; collects the booty at his leisure, and suspends himself as before. He will sometimes even spring from the rock, and, with a fowling-net fixed to the end of a staff, catch the old birds that are flying around their retreats. At other times the party go in a boat to the foot of the precipice; and one of the most daring, with a rope about his middle, and a long pole, with a hook at one end, in his hand, either climbs, or is pushed by his companions, to the nearest footing place. By means of the rope he draws up the other adventurers in succession, each provided with his cord and fowling staff. In this manner they proceed upwards, till they reach the habitations of the birds; and the booty is slung down into the boat, which is rowed along to attend their operations. They frequently divide themselves into pairs, and proceed in different directions; and when they discover the nests of the birds below their station, one of them suffers himself to be let down by his companion, depending upon his single strength for safety. In these perilous pursuits the fowlers often spend seven or eight days at a time, and lodge during the night in the recesses of the rock.

In Mexico and China aquatic birds are taken by the natives in the following very simple but ingenious manner. Empty gourds are left continually floating on the lakes, to which the birds resort, that they may be accustomed to approach them without alarm. The bird-catcher enters the lake with his body under water, and his head covered with a gourd; quietly advances to the ducks and geese that are swimming on the surface, and pulls them by the feet under the water, securing in this manner as many as he can carry away.

In some of the remoter parts of Russia, great quantities of golenottes or grouse are taken by a large funnel, or inverted cone, which is made of long birch twigs stuck in the earth, very near to each other, and forming an opening at the top, about a yard in diameter. In this opening is placed a wheel made of two circles, intersecting each other, surrounded with straw or ears of corn, and turning on an axis fastened to the sides of the funnel. Above the cone is a cross stick, which rests upon two long forks planted upright, and from which is suspended a bundle of ears of corn. The birds, first of all, perch upon this transverse piece of wood; and then descend to the corn placed upon the wheel. As soon as

they alight upon one of the projecting parts of the circles, the wheel turns, and they fall headlong to the bottom of the trap.

In different parts of Italy, the wild pigeons, on their return from the northern and western countries of Europe, are caught by means of nets, which are stretched across the hollows of the mountains, through which the birds direct their course. These nets are hung upon trees or lofty poles planted for the purpose; and, by means of a pulley, are made to drop in a heap upon the slightest impulse. A watchman is stationed, on a lofty circular turret, at a little distance from the place where the snare is laid; and when he observes the doves approaching, he slings a stone, or shoots an arrow trimmed with hawk's feathers above them. Upon this, the whole flock, apprehending the object as it is falling down to be a bird of prey, descend with the utmost speed, to pass under the trees; dash in a body against the net, which instantly falls to the ground; and are thus entangled in such a manner, as to become an easy prey to the active hand of the fowler. See a variety of other modes of bird-catching detailed in Pennant's *Birds of Great Britain. Encyclopedie Methodique. Arts et Metiers*; tom. v. p. 573. Reaumur, *Histoire des Insectes*, tom. vi. Buffon, *Histoire des Oiseaux*, particularly the articles *Allouette Spirolette, Rouge-gorge, Motteux ou cul-blanc, Mesange, Becasse, Pluvier.* (y)

BIRD-LIME, a glutinous matter of a very peculiar nature, is employed for catching birds, mice, and other vermin; and prepared from different substances, in a great variety of ways. In former times, it was made chiefly from the berries of the mistletoe of oak, which were first boiled in water, then pounded, and the water poured off, in order to carry away the seeds and rhind. In England, it is generally made from the middle bark of holly, which is boiled in water, seven or eight hours, till it become soft and tender. After the water has been drained off, it is laid in masses in the earth, covered with stones, and left to ferment during a fortnight or three weeks. When thus changed into a kind of mucilage, it is taken from the pit; pounded in mortars till reduced to a paste; washed and kneaded in river water till freed from all extraneous matters. It is left in earthen vessels, four or five days, to purify itself by fermentation; and is then put up for use or commerce. In every kingdom, however, and almost in every district, there is a different mode of preparing this substance; and some profess to make a secret of their peculiar process. The mode employed by M. Bouillon Lagrange is, to take a sufficient quantity of the second bark of holly, to bruise it well, and boil it in water four or five hours; to pour off the water, to deposit the bark in pits in earthen pans, to moisten it from time to time with a little water; to let it remain till it become viscous, and to cleanse it by washing, when it has obtained a proper degree of fermentation.

Bird-lime may be procured from the young shoots of the common elder tree, and from the second bark of the *viburnum*, or wild vine; from the roots of hyacinth, narcissus, asphodel, and black bryony; from slugs, snails, and the pods of certain caterpillars; but the best is that which is made from the prickly holly, and which is of a greenish colour. That which comes from Italy is made from the mistletoe; and that from Damascus is supposed to be procured from sebestins, as their kernels are frequently found amongst it. The bird-lime of commerce,

in general, is seldom in a pure state, and is frequently a mixture of vegetable and animal substances.

The common kind of bird-lime readily loses its tenacious quality, when long exposed to the air, and particularly when subjected to moisture; but it may be rendered capable of sustaining the action of water, by the following process: Take a pound of common bird-lime, and wash it thoroughly with spring water, till its hardness be destroyed. Then pound it completely, that its water may be entirely separated; and, when it is well dried, put it into an earthen pot, with as much goose or capon's grease as will make it run. Add two spoonfuls of strong vinegar, one of oil, and a small quantity of Venice turpentine; and let the whole boil for a few minutes over a moderate fire, stirring it all the time. It is then ready for use; and is the only kind, that can be successfully used for snipes and other birds, which frequent wet situations.

When bird-lime is about to be applied to use, it should be made hot; and the rods or twigs should be warmed a little before they be dipped in it. When straws and cords are to be limed, it should be very hot; and, after they are prepared, they should be kept in a leather bag till used. In order to prevent bird-lime from being congealed by cold, it should be mixed with a little oil of petroleum; and, indeed, before the common kind can be used at all, it must be melted over the fire with a third part of nut oil, or any thin grease, if that has not been added in the preparation.

Bird-lime has generally been classed among the immediate productions of vegetables; and Fourcroy was the first person who considered it as of a glutinous nature. It has been carefully analysed by M. Bouillon Lagrange, and has been found to resemble gluten in many particulars; but differs from it essentially in the acetic acid which it contains; in being very slightly animalized; in the mucilage and extractive matter which may be obtained from it; in the great quantity of resin which it yields by means of nitric acid; and in its solubility in ether. See *Annales des Chimie*, tom. lvi. *Analyse de Glu*, par M. Bouillon Lagrange. Fontenelle *Hist. Acad. Scien.* 1720, p. 12. *Collection Acad.* tom. v. p. 170. *Philosophical Magazine*, vol. xxiv. *Dictionnaire de l'Industrie*, art. *Glu*. (g)*

* Dr Thomson, in considering the characters of bird-lime, which are made principally from the experiments of Lagrange, as it owes its peculiar properties to the

BIRD-ISLAND, the name of an immense rock in the Southern Pacific Ocean, discovered in 1788 by the commander of the Prince of Wales, who gave it this name from the vast flocks of birds by which it was frequented. It was visited by Vancouver in March 1794. Towards the north-east and west, it opposes an inaccessible and rugged front to the violence of the waves, which beat upon it with tremendous effect. To the south the height of the rock diminishes; and towards its western side there is a sandy beach, where it might not be difficult to effect a landing, under favourable circumstances. A little verdure enlivened this part of the island; but in every other quarter it is destitute of soil and vegetation. It is called *Moodoo Manno*, or the Isle of Birds, by the Sandwich islanders. It is only about three miles in circumference, and is situated about 117 miles from Onehow, one of the Sandwich isles. "From its great distance from all other islands," says Vancouver, "and its proximity to their islands, it seems to claim some distant pretensions to be ranked in the group of the Sandwich Isles." E. Long. 198° 8', N. Lat. 23° 6'. See Vancouver's *Voyages*, vol. v. book v. chap. v. p. 136—140. (j)

presence of an analogous substance, gives the name of bird-lime to the principal itself. Natural bird-lime differs from that of the artificial; while the former exudes spontaneously from plants, the latter is prepared from different substances. Natural bird-lime is of a green colour, insoluble in water, but soluble in ether, as well as in essential oils. When exposed to the air, it continues glutinous, never becoming hard and brittle like the resins. Artificial bird-lime, prepared either from the berries of the mistletoe, the middle bark of the holly, or from other substances of a similar nature, has a greenish colour, and possesses a gluey, stringy, and tenacious consistence. Besides some other characters, which will be mentioned under the article CHEMISTRY, it forms with a concentrated solution of potash a whitish magma, which becomes brown by evaporation. According to analysis, artificial bird-lime contains acetic acid, mucilage, and several alkaline and earthy bodies, which are considered, however, as foreign substances. Bird-lime, in a state of putrefaction, which was the case with some I had in my possession, emits a large quantity of the light carburetted hydrogen gas; the smell of which being not unlike that of the gas obtained by the distillation of wood and coal, or that of the intestinal gas.

CUTBUSH.

BIRMAN EMPIRE.

THIS new empire is one of the most powerful states in Asia, and includes the ancient kingdoms of Ava, Pegu, and Arracan, with some other countries of inferior note. It is difficult to ascertain with precision the limits of this empire; but, according to the most accurate accounts, it appears to extend from 92° to 102° east longitude, and between 9° and 26° north latitude, and is about 1200 miles in length, and 700 in breadth. On the north it is bounded by Assam, Tibet, and China; on the west it is separated from the British dominions in India by a range of mountains, the small river Naaf, and the bay of Bengal; the southern and eastern boundaries have not yet been accurately ascertained.

The kingdom of Ava, the original seat of the Birman government, was formerly subject to the king of Pegu; but about the middle of the 16th century, the Birmans excited a revolution in the latter kingdom, and they maintained their supremacy over it until about 1740, when several of the provinces revolted, and kindled the flames of a civil war, which was prosecuted on both sides with savage ferocity. Success was long doubtful; but at length the Peguers obtained several victories over the Birmans, and they pursued these advantages with so much vigour, that in 1752 they invested Ava, the capital. Disheartened by repeated defeats, the Birmans, after a short siege, surrendered at discretion; and the sovereign, the

last of a long line of native princes, was made prisoner with all his family, except two of his sons, who effected their escape to Siam, where they met with a friendly reception, and were flattered with assurances of security and succour. Having thus completed the conquest of Ava, the king of Pegu returned to his own country, leaving his brother to govern the capital of the royal captive, whom he carried with him, and afterwards cruelly murdered. At first, matters had the appearance of tranquillity and submission; the principal inhabitants acknowledged the authority of the conqueror, and took an oath of allegiance to him. Among the rest, Alompra, the chief of a small village, but a man who possessed a spirit of enterprise and boldness equal to the most arduous undertakings, at first dissembled his views, though at the same time, he harboured the hope of emancipating his country, and meditated the best means of accomplishing his purpose. Having in the neighbourhood about 100 devoted followers, on whose courage and fidelity he could safely rely, he ventured with this handful to attack the troops of the conqueror, and being afterwards further supported by his countrymen, he in 1753 regained possession of Ava, the capital. A bloody and cruel contest ensued; and though Alompra laboured under great disadvantages, and met with various disasters, yet victory usually crowned his exertions: He at length drove the enemy from the kingdom of Ava, and in 1757 he even invested Pegu, the capital of the conqueror. After some time, the city was taken and given up to indiscriminate plunder: the king himself was made prisoner, and after being kept in captivity for about 20 years, was cruelly put to death by one of Alompra's successors. Having thus conquered the kingdom of Pegu, and annexed it to the Birman monarchy, Alompra proceeded to bring under his subjection, the countries to the eastward, including the fertile districts between Pegu and the three Pagodas: he also reduced Javoy under his dominion, and afterwards proceeded to chasten the Siamese for the support and encouragement which they had afforded his enemies. After various achievements, the victor advanced towards the capital of the kingdom; but two days after the commencement of the siege, he was taken ill of a disease which he foresaw would prove mortal, and he therefore gave orders for an immediate retreat; but before he reached the seat of his empire, he died, May 15, 1760, in the 50th year of his age, regretted by his people, who at once venerated him as their monarch and deliverer. Alompra, whether viewed in the light of a soldier or a politician, is undoubtedly entitled to high respect. The wisdom of his counsels secured what his victories acquired; he was not more eager for conquest than attentive to the improvement of his territories, and the prosperity of his subjects; he issued a severe edict against gambling, and prohibited the use of spirituous liquors throughout his empire: he reformed the courts of justice, abridging the power of the magistrates, and prohibiting them to decide at their private houses on criminal causes, or with regard to property, when the amount exceeded a certain sum: and every process of importance was to be decided in public, and every decree registered. The reign of Alompra though short, was vigorous; and if his life had been prolonged, he would probably have proved the benefactor of his country in a still higher degree.

Alompra, the founder of the Birman empire, was

succeeded in the throne by his eldest son Nam-ogee, who, after suppressing various insurrections, and promoting the internal improvement of the country, died in 1764. He left behind him an infant son named Mornien; but Shembuan, the uncle and natural guardian of the young minor, deprived him of the crown, and took the reins of government into his own hand. On ascending the throne, the new monarch declared war against the Siamese, and after various rencounters, they were completely defeated by his army in a general battle. The forces of Shembuan immediately proceeded to invest Siam, the capital of the kingdom; but as the fort was of considerable strength, the besiegers were content with maintaining a passive blockade, the favourite system of Birman warfare. In a short time the king of Siam, in despair, secretly withdrew from the fort, in order to avoid falling into the hands of the enemy; and eluding the Birman outposts, sought refuge among the hills, where he is said to have perished, though by what means is unknown. The Siamese, deserted by their sovereign, agreed to capitulate; the fortifications of the city were destroyed, and a governor was appointed over it, who took an oath of allegiance to the Birman monarchy, and engaged to pay an annual tribute. However, though they were beaten, the spirit of the nation was not subdued. The conqueror had no sooner withdrawn his army, than one of the king's relations returned at the head of a numerous troop of adherents, displaced the new government of Siam, and abolished the regulations of the Birman commander. Shembuan dispatched a new army to suppress the insurrection, but in consequence of the treachery and rebellions of the Peguese soldiers who composed it, the operations against the Siamese were completely suspended, and the nation was saved from destruction.

In the mean time, however, the Birmans had successfully repelled the invasion of their territories by the Chinese government, who, with the view of subjugating them to its dominion, sent in 1767 an army of 50,000 into one of the northern provinces. The troops of Shembuan advanced to meet them, and surrounded the Chinese on all sides, so that a retreat became impracticable, and to advance was desperate. In this situation the Birmans attacked the enemy with impetuosity, while, on the other hand, the defence made by the Chinese was equally resolute. After a conflict of three days, the latter, in an effort of despair, tried to force their way through one of the divisions of the Birman army. The attempt proved fatal. They sunk under the pressure of superior numbers, and the carnage that ensued was dreadful. Not an individual of the Chinese army returned home to relate the melancholy tale, and only about 2500 were preserved from the sword, who were conducted in fetters to the Birman capital. Various employments were assigned them, and they were encouraged to marry native women and settle in the country; circumstances which confer valuable privileges even on slaves taken in war.

Such were some of the principal events of Shembuan's reign. At length, after various other military exploits, in the course of which he subjected to a state of permanent vassalage several of the neighbouring provinces, he died in 1776, and was succeeded in the government by his son Chengenza. The new prince, unlike his predecessors, was the slave of his pleasures and the tyrant of his people. During his reign, the

military operations of the Birmanians appear to have been completely suspended, whilst the neighbouring nations, who had so recently experienced the power of their arms, felt no inclination to become the aggressors. At last, in consequence of his numerous acts of savage cruelty, a formidable conspiracy was excited against him, headed by one of his uncles: the conspirators surrounded his palace, and though he saved himself by flight, yet after various adventures, he was slain in 1782, and fell unlamented, as he had lived despised by his people.

Shembuan Menderagee, the head of the conspiracy, was the fourth son of Alompra, and had carefully concealed under an humble exterior, and an apparent love of retirement, ambition that aspired to the possession of the crown; and though Mornien, who was formerly deprived of the kingdom when a minor by his uncle Shembuan, and placed in retirement under the care of the priests, was now raised to the throne, he enjoyed his dignity only eleven days. Menderagee, who was also his uncle, seized on the reins of government, and made Mornien prisoner. Deposition and imprisonment, however, did not satisfy the usurper; but without assigning any cause, or granting even the form of a trial, the unfortunate nephew was, by his uncle's orders, drowned in the river between two jars, conformably to the Birman mode of executing members of the royal family. Desirous of extending his dominions, the new king in 1783 attacked the Rajah of Arracan, and in the short space of a few months accomplished the conquest of that kingdom, which, with its dependencies, was formed into a province of the Birman empire. He next directed his arms against Siam, which, since the attack by Shembuan, had enjoyed some respite from hostility, and was beginning to recover its ancient vigour. In his first attempt he was foiled, and being mortified with the disappointment, he resolved, as soon as possible, to retrieve the disgrace which his arms had sustained. With this view, he marched in the spring of 1786 at the head of 30,000 men; but he had scarcely entered the territories of the enemy, when he was opposed by the king of Siam, and after a furious engagement completely routed. In the following year the Siamese made an unsuccessful invasion of the Birman empire; and at last in 1793, they concluded a treaty of peace highly favourable to the Birman interests. Soon after this, some of the Birman troops made an incursion into the British territories, in search of some banditti who had taken refuge in our dominions. Though at first this circumstance had a threatening aspect, yet the robbers, as they were found guilty of the charges brought against them, were delivered up, and the whole affair was amicably settled. At the same time, this event furnished us with the opportunity of acquiring more accurate knowledge of a people whose situation, extent of territory, and commercial connections with British India, rendered a liberal intercourse with them highly desirable. In order to promote this important object, the governor-general Sir John Shore, now Lord Teignmouth, sent Captain Symes on an embassy to the Birman court, and it was on this occasion that we acquired the principal information that we possess of the present state of this empire.

The climate of the Birman empire appears to be very healthy and agreeable. The seasons are regular, and the extremes of heat and cold are seldom experienced for any considerable length of time. Immediately be-

fore the commencement of the rains, the heat indeed becomes very intense, but it is only of short duration. Towards the end of May, Colonel Symes found the thermometer at 98° about noon.

The soil of the southern provinces of the Birman empire is remarkably fertile, and produces as luxuriant crops of rice as are to be found in the finest parts of Bengal; but in some parts extensive plains are to be seen, on which the vestiges of cultivation are evident, which have been desolated by the ravages of war during the contest between the Birmanians and the Peguese, so that the finest territories in the world have in many places become the domain of the wild beasts of the forest. In the northern parts of the empire, the country is irregular and mountainous; but the plains and valleys, particularly near the rivers, are exceedingly fertile. They yield excellent wheat, and the various kinds of small grain which grow in Hindostan, with most of the different species of esculent vegetables. Sugar canes, tobacco of a superior quality, cotton, indigo, and the various tropical fruits, are natural products of this country. The art of agriculture, however, is still in a state of imperfection; but this does not seem to arise so much from want of skill in the people as from their present situation, which renders great exertion to procure subsistence by no means necessary. The Birmanians are in a state similar to that of a colony in a new territory: land is cheap and abundant, while labour is procured with difficulty; and hence, they cultivate only the most fertile spots, and even then only in an indifferent manner, leaving the greater part of the work to nature, which has been very bountiful to this country. In some quarters, however, neat farms are to be seen; the lands are fenced and divided into inclosures to receive the cattle, of which there are great abundance; the fields are divided by thorn hedges; the low grounds are prepared for rice, and the higher lands are planted with leguminous shrubs, or left for pasture. The cattle used in some parts of the country for draft and tillage are remarkably good; they employ only two of them in the plough, which turns up the soil very superficially. In their large carts they put four strong oxen, which are driven at the gallop by a girl standing up in the vehicle, who manages the reins and whip with ease and dexterity. In consequence of many parts of the country remaining in a state of nature, the woods are large and numerous, affording an abundant supply of various kinds of timber. The monarch of the Birman forests, however, is the teak tree, which grows in great plenty in the southern parts of the empire, near the large rivers, and is considered as superior to the European oak. This species of wood is of peculiar importance to our settlements in India for ship-building, and is on this account one of the most valuable productions of the country.

The Birman empire abounds in minerals. There are several mines of gold and silver in this country, and the former metal is likewise found in the beds of streams which descend from the mountains. Precious stones are also met with in various parts of this country, as rubies, sapphires, amethysts, garnets, chrysolites, jaspers, loadstone, and marble equal in quality to the finest of Italy. The inferior minerals, as iron, lead, tin, antimony, arsenic, sulphur, are also found in great abundance. The Birmanians have likewise natural wells of petroleum, similar to the coal tar for which Europe is indebted to the ingenuity of lord Dundonald. Captain

Cox mentions, that at one place there are upwards of 500 pits or wells of this useful production. The animals of this country correspond in general with those of Hindostan, so that they will not require any particular description.

The manufactures of the Birman empire consist chiefly of cotton and silk goods, saltpetre, gunpowder, various kinds of pottery, marble statues of the idols they adore. At a certain village, colonel Symes saw thirty or forty large yards crowded with statues at work on images of various sizes, but all of the same personage, namely Gadama, sitting cross legged on a pedestal. The quarries, from which they obtain the materials, are only a few miles distant. The marble is brought to the village in blocks; and after being cut, the images are sold to the natives. The smallest exceeded the human stature, and the price was said to be 100 tackals, or about 12 or 13 pounds sterling; but some diminutive images were so low as two or three tackals. The workmen were civil and communicative. Their tools were a chissel and a mallet, and they smooth the images with freestone and water. Many of the idols were beautifully polished, which is said to be done by rubbing the marble with three different kinds of stone; the first rough, the second finer, and the third such as hones are made of. The workmen afterwards use the palms of their hands, an operation which gives the images a transparent clearness far surpassing the brightest polish that European marble ever exhibits. Of late years, the Birmans have made rapid progress in the art of ship-building. Formerly they used only small vessels like boats; but, in consequence of their communication with Europeans, they are now launching vessels of considerable magnitude. When the British embassy was at Raugoon, the principal port of the Birmans, colonel Symes saw several ships on the stocks from 600 to 1000 tons burden: three or four of the vessels belonged to English adventurers. Ships may be constructed in this country at one third less than in the Ganges, and for nearly one half of what they would cost at Bombay. The Birman shipwrights appear to finish their work well; they are of an athletic form, and possess in an eminent degree that vigour which distinguishes Europeans, and gives them a vast superiority over the enervated natives of Hindostan. It is said, however, that the ships of Pegu are not so firmly made as those constructed in our ports. The art of vitrification has long been known in the East, but the inhabitants are unable to make so hard and transparent a substance as that which is brought from Europe. On the subject of this manufacture, colonel Symes mentions the following curious and interesting fact: "The Birman monarch," says he, "who is a great admirer of this manufacture, was particularly desirous to introduce it into his own dominions; and supposing that every Englishman must be versed in the knowledge of making whatever comes from his own country, he sent a message, to request that I would furnish his artificers with such instructions as might enable them to fabricate glass of a quality equal to what was made in England. Unluckily none of us happened to be skilled in the mystery of a glass-house; all, therefore, that we could do, was to explain the principles of the art, which Dr Buchanan obligingly undertook; and, in order to facilitate them in the acquirement, and guide them in the practice, I lent them the *Encyclopaedia Britannica*, and pointed out the article where the process is fully explained. Baba Sheen, the

second in authority at the port of Raugoon, and the Armenian interpreter, translated it into the Birman tongue."

The commerce of the Birman empire is very considerable. An extensive trade is carried on between the capital and Tanan in China. The principal export from the Birman territory is cotton, of which it is said there are two kinds, one of a brown colour, of which nankeens are made, the other white like the cotton of India. This commodity is transported up the Irrawaddy in large boats as far as a place called Bamoo, where it is bartered with the Chinese merchants, who convey it partly by land and partly by water into China. Amber, ivory, precious stones, betel nut, and the edible nuts brought from the eastern archipelago, are also articles of commerce. In return the Birmans procure raw and wrought silks, gold leaf, preserves, paper, and some hardware utensils. There is also a considerable inland commerce carried on between the different parts of the interior, particularly in the necessaries of life. Several thousand boats are employed in transporting rice and salt from the southern provinces, to supply the capital and the northern districts. On the coast the Birmans possess several excellent ports, particularly Negrais, Mergui, and Raugoon. The imports into the latter place from the British settlements in 1794-5, colonel Symes was informed, amounted to about 135,000*l.* Sterling. They consisted chiefly of coarse piece goods, glass, hardware, and broad cloth: the returns were made almost wholly in timber. In order to encourage our trade with this country, the king, upon our embassy in 1795, granted several valuable privileges to our merchants. The Birmans are so sensible of the advantages of commerce, and so desirous of extending it, that of late years they have tolerated all descriptions of people, Pagans, Jews, Mahometans, Christians, the disciples of Confucius, and the worshippers of fire, and invited strangers of every nation to resort to their ports; and being free from the prejudices of cast which shackle their Indian neighbours, they permit foreigners to intermarry and settle among them. The children of strangers of every description born of a Birman woman become subjects of the state, and are entitled to the same privileges as if they had sprung from a line of Birman ancestry. In their commercial transactions, the Birmans, like the Chinese, make no use of coin. Silver in bullion and lead are the current monies of this country; weight and purity are of course the standard value, and in ascertaining these the natives are exceedingly scrupulous and expert. Money scales and weights are all fabricated at the capital, when they are stamped and circulated throughout the empire, while the use of any other is prohibited. The bankers are also workers in silver, and assayers of metal. This is a very numerous class of people, and indispensably necessary, as no stranger can undertake either to pay or receive money, without having it first examined by one of them. Every merchant has a banker of this description, with whom he lodges all his cash, and who receives a commission of one *per cent.* upon it, in consideration of which he is responsible for the quality of what passes through his hands; and there has been no instance, in which a breach of trust was committed by one of these bankers.

In this place we shall introduce some description of the principal cities of the Birman empire, as it will illustrate the state of society and of the arts in this country. The seat of government has been often successively

changed under different sovereigns. At present the capital is Ummerapoora, a city which was founded by Menderagee, soon after he ascended the throne, and which has speedily become one of the most flourishing places in the East. It is situated on a peninsula, between a lake on the south-east and a large river with numerous isles on the north-west, and with its spires, turrets, and lofty obelisk, &c. noting the royal presence, seems to rise like Venus out of the waters. The lake is called Tounzemahn, from a village on the opposite side, which is ornamented with tall groves of mango, palmyra, and cocoa trees. The number and singularity of the boats which are moored in the lake, and the surrounding amphitheatre of lofty hills, conspire to render the scene grand and interesting. The fort is an exact square, with public granaries and store-rooms, and there is a gilded temple at each corner nearly 100 feet in height, but far inferior to others in the vicinity of the capital. In the centre of the fort stands the royal palace, with a wide court in front, beyond which is the hall of council, supported by about eighty pillars, disposed in eleven rows. The buildings of this city are chiefly of wood.

Ava, the former capital, is about four miles from Ummerapoora; but since the removal of the seat of government to that city, has fallen into a state of decay. "The walls," says colonel Symes, "are now mouldering into ruin, ivy clings to the sides, and bushes suffered to grow at the bottom, undermine the foundation, and have already caused large chasms in the different faces of the fort. The materials of the houses, consisting chiefly of wood, had, on the first order for removing, been transported to the new city of Ummerapoora: but the ground, unless when it is covered with bushes or rank grass, still retains traces of former buildings and streets. The lines of the royal palace, of the grand council hall, the apartments of the women, and the spot on which the peasath or imperial spire had stood, were pointed out to us by our guide. Clumps of bamboos, a few plantain trees, and tall thorns, occupy the greater part of the area of the lately flourishing capital. We observed two dwelling houses of mortar and brick, the roofs of which had fallen in. These, our guides said, had belonged to foreigners. On entering one, we found it inhabited only by bats, which flew in our faces, whilst our sense of smelling was affected by their filth, and by the noisome mildew that hung upon the walls. Numerous temples, on which the Birman never lay sacrilegious hands, were dilapidating by time. It is impossible to draw a more striking picture of desolation and ruin."

Pegu was formerly capital of the kingdom of that name: but after the conquest of it by Alompra, who demolished the buildings, and razed the whole to the ground, it fell into decay. But after Menderagee ascended the throne, he endeavoured to conciliate the native Peguese, by permitting them to rebuild their ancient city, within the site of which a new town has accordingly been reared. It is situated in 17° 40' N. Lat. and 96° 11' 15" E. Long. The number of inhabitants appears to be about six or seven thousand.

Besides these cities, there are many others of considerable importance. Raugoon, one of the principal ports in the kingdom, was founded by Alompra, and is estimated to contain about 30,000 inhabitants. Towards the mouth of the river Pegu stands Siriam, formerly one of the chief ports of that kingdom, and which carried

on a considerable commerce when in possession of the Portuguese. Martaban was another sea-port of considerable eminence, until the harbour was impeded by order of the Birman emperor. The grand river Irrawaddy, the course of which is about 1200 miles in length, is adorned with numerous towns and villages. Persian or Bassian stands on its western branch. At a considerable distance to the north is Prome, celebrated as the scene of many long sieges and bloody battles, the population of which is said to exceed that of Raugoon. Chagaing, opposite to the capital, was once a city of imperial residence, and is still a principal market for cotton. Pagahn is celebrated for its numerous temples, but is now in a state of decay. Towards the north and west there are also Arracan, Quaugtong, Barnoo, Munnipora, Monchaboo.

Of the population of the Birman empire we have no accurate information. Colonel Symes, however, says, that he was credibly informed the number of cities, towns, and villages, amounted to 8000, exclusive of Arracan. Now, if this be true, and we suppose each of them, on an average, to contain 300 houses, and every house six persons, the population will amount to 14,400,000 persons. Few of the inhabitants, however, live in solitary houses; they mostly form themselves into small societies, and their dwellings, thus collected, compose their villages; and therefore, he concludes, that if we estimate the whole population, including Arracon, at 17,000,000, it will not probably exceed the truth.

In their features the Birman bear a greater resemblance to the Chinese than to the natives of Hindostan. The men are not tall, but they are active and athletic, and have a very youthful appearance, as, instead of using the razor, they pluck out their beards. They tattoo their thighs and arms with various fantastic shapes and figures, which they consider as a powerful charm against the weapons of their enemies. The women, especially in the northern part of the empire, are fairer than the Hindoo females; but they are not so delicately formed, and, in general, they are inclined to corpulency; their hair is black, coarse, and long. At an early age, the girls are taught to turn their arms in such a manner as to make them appear distorted. When the arm is extended, the inside of the joint is protruded, and the external part bends inwards. Neither the men nor the women are so cleanly in their persons as the Hindoos, among whom diurnal ablution is a religious and moral duty.

In general, the character of the Birman forms a striking contrast with that of the natives of India, from whom they are separated only by a narrow range of mountains; and yet, notwithstanding the small extent of the barrier, the physical difference between them could scarcely have been greater if they had been situated at the opposite extremities of the globe. The Birman are a lively, inquisitive, intelligent race; and, at the same time, active, irascible, and impatient. In some respects they display the ferocity of barbarians, and in others all the softness, humanity, and tenderness of polished society. They inflict the most savage vengeance on their enemies; as invaders, desolation marks their steps, for they spare neither age nor sex: but in their own country they assume a different character; then they manifest the spirit of benevolence, and extend their aid to the sick, the infirm, and the aged. In this country beggars are never seen; for if any individual is unable

to procure sustenance by his own labour, it is provided for him by others. Filial piety is inculcated as a sacred duty, and its precepts are religiously observed.

The private houses of the Birman are constructed of very simple and cheap materials. The use of brick, or stone, is prohibited by government, so that they are constructed of wood; but, in other respects, they are built with sufficient attention to conveniency, and are all raised from the ground, either on wooden posts, or bamboos, according to the size of the building. In consequence, however, of the houses being constructed of such combustible materials, the inhabitants are under continual apprehension of fire, against which they take every precaution. The roofs are lightly covered; and, at every door, there is a long bamboo, with an iron hook at the end of it, to pull down the thatch. There is also another pole, with an iron grating at the extremity, to suppress the flames by pressure; and almost every house has earthen pots filled with water, standing ready upon the roof; and a number of firemen patrol the streets during the night, to put out all fires and lights after a certain hour. The art of masonry has not, in late ages, been much cultivated among the Birman, as their wooden structures have superseded the solid buildings of brick and mortar; and it is a singular circumstance, that though well constructed arches of brick are still to be seen in many of the ancient temples, yet native workmen are no longer able to turn them.

The court dress of the nobles is represented as very becoming. It consists of a long robe of flowered satin, or of velvet, reaching to the ankles, with an open collar, and loose sleeves. Over this there is a scarf, or flowing mantle, which hangs from their shoulders; and on their heads they wear high caps of velvet, either plain, or of silk embroidered with flowers of gold, according to the rank of the owner. Ear-rings are worn by the men, and some persons of condition use tubes of gold, about three inches long, and as thick as a large quill, which expands at one end like the mouth of a trumpet; others wear a heavy mass of gold, beaten into a plate, and rolled up. This lump of metal forms a large orifice in the robe of the ear, and drags it down by its weight to the extent of two inches. Men of rank wear, in common dress, a tight coat, with long sleeves, made of muslin, or of very fine nankeen, and a silk wrapper that encircles the waist. The working class are usually naked to the middle; but, in cold weather, they sometimes make use of a mantle or vest of European cloth. When women of quality go abroad, they wear a silk sash like a long shawl, which crosses their bosom, and is cast over the shoulder, so as to flow gracefully on each side. The lowest class of females often wear only a single garment, in the form of a sheet, which, wrapped round the body, and tucked under the arm, crosses their breasts, which it scarcely conceals, and descends to their ankles, but in such a manner that the legs protrude from under it when they attempt to walk. Women in full dress stain the palms of their hands and their nails of a red colour, by means of a vegetable juice, and strew on their bosoms powder of sandal wood, or of a particular kind of bark, with which some of them rub their faces. Both men and women tinge the edges of their eyelids and their teeth of a black colour.

In their food, the Birman, compared with the Hindoos, are gross and uncleanly. Although their religion prohibits the slaughter of animals in general, yet they

apply the interdiction only to those that are domesticated. All game is eagerly sought after, and is publicly sold in the market. Reptiles also, as lizards, guanas, snakes, constitute part of the food of the lower classes, and they are also extremely fond of vegetables. The higher ranks live with greater delicacy, although their fare is never sumptuous.

With regard to their various circumstances, particular attention is paid to the rank of the individuals. In their houses, no one dare assume a mode of structure to which he is not legally entitled, under the penalty of a most severe punishment, which is never remitted. This subordination of ranks among the Birman is maintained, not only with regard to their houses and dress, but even in their domestic instruments; the shape of their betel box, which is carried by an attendant before one of noble birth wherever he goes, his ear-rings, his cup of ceremony, the accoutrements of his horse, and even the metal of which his spitting box and drinking cup are made.

Among the Birman, marriages are not contracted until the parties attain the age of puberty. When a young man wishes to marry a girl, her mother, or nearest female relation, first makes the proposal in private; and, if it is well received, a party of his friends afterwards proceed to the house of the lady's parents, with whom they adjust the marriage portion. On the morning of the bridal day, the bridegroom sends the maiden three lower garments, three sashes, and three pieces of white muslin, with such jewels, ear-rings, and bracelets, as his circumstances will afford. The parents of the bride prepare a feast, and formal writings are executed. The young couple eat out of the same dish, and the bridegroom presents the bride with some læpack, or pickled tea, which she accepts, and returns the compliment, which ends the ceremony. The law prohibits polygamy, and recognises only one wife; but concubinage is admitted to an unlimited extent. The concubines reside in the same house with the legitimate wife, and are obliged by law to perform the menial services of the family; and when she goes abroad, they attend her, bearing her water flaggon, betel box, fan, &c. When the man dies, his concubines, if bound in servitude to him, become the property of the surviving widow, unless he has emancipated them by a specific act previous to his decease.

In the Birman empire, prostitution is admitted, and is often attended with circumstances of peculiar wretchedness. Many who follow this course of life are not at their own disposal, nor do they receive the earnings of their unhappy professions. According to the Birman laws, if a person contracts a debt which he is unable to pay, he becomes the property of his creditor, who may claim the insolvent debtor as his slave, and oblige him to perform menial service until he liquidates the debt; nor does the unhappy man suffer in his own person only, for his immediate relations are often included in the bond, and are liable to be attached and sold to discharge the obligation. In consequence of this inhuman law, whole families are often plunged into misery and ruin. Innocent women are dragged from the comforts of domestic life, and, on account of the folly or misfortune of the master of the family, are sold to the superintendent of the Jackally, who, if they possess particular attraction, pays a valuable consideration for them, and reimburses himself by the wages of their prostitution. Indeed, the lower classes of the Birman make no scruple

of selling their daughters, or even their wives, to foreigners, who come to pass a temporary residence among them: this, however, reflects no disgrace on any of the parties, and even the woman is not dishonoured by the connection. But when a man leaves the country, he is not at liberty to carry his temporary wife along with him; and even female children, born of a Birman mother, are not allowed to be taken away. Men may emigrate from the country; but the Birmans think, that the expatriation of women would impoverish the state, by diminishing the sources of population. On this point the law is extremely rigorous. Before a ship receives clearance, it is carefully searched by the officers of the customhouse; and even if their vigilance should be eluded, the woman would quickly be missed, and should the vessel ever return to a Birman port, the property would be confiscated, and the master subjected to fine and imprisonment.

The Birmans do not shut up their women in the walls of a haram, or surround them with guards, like most other nations of the East. Such low jealousy forms no part of the character of this extraordinary people. They do not conceal their wives or daughters from the eyes of men, but allow them to have as free intercourse with the world as the rules of European society admit of. Infidelity, however, is not common among the Birman women. Indeed, they have in general too much employment to allow time for the corruption of their minds, for even women of the highest rank seldom sit in idleness at home. The female servants, like those of the Grecian dames of antiquity, ply the various labours of the loom, whilst the mistress of the house superintends and directs their industry. Col. Symes mentions, that, on occasion of a formal visit to the mother of the present queen, they observed, in one of the galleries of his palace, three or four looms working by the damsels of his household. Indeed, weaving is chiefly a female occupation, and most females make all the cotton and silk cloth that is necessary for domestic consumption. In some respects, however, women are treated as if they did not hold the same place in the scale of creation as the men. The evidence of a female is not received as of equal weight with that of a man, and they are not allowed to ascend the steps of a court of justice, but are obliged to deliver their testimony on the outside of the roof.

Among the public amusements of the Birmans, are boxing matches, fireworks, processions, exhibitions of dancing, puppet shows. They are particularly fond of dramatic entertainments. At Pegu there is a theatre, in an open court, which is splendidly illuminated by lamps and torches when theatrical performances are exhibited. Indeed, at all festivals they have dramatic entertainments, consisting of music, dancing, and action, with a dialogue in recitation. The higher ranks are likewise particularly fond of chess. The board which they use in this game is exactly similar to ours, containing 64 squares, and the number of troops the same, sixteen on each side; but the names, the power, and the disposal of them, differ essentially. On the last day of the year a curious custom prevails throughout the Birman empire. To wash away the impurities of the past, and commence the new year free from stain, women on this day are accustomed to throw water on every man they meet, and the men have the privilege of retaliating. This licence gives rise to a great deal of harmless merriment, particularly among the young

women, who, armed with large syringes and flaggons, endeavour to wet every man that goes along the streets; and, in their turn, receive the same compliment with perfect good humour. Dirty water, however, is never employed; nor is a man allowed to lay hold of a woman, but he may cast as much water over her as he pleases, provided she has been the aggressor; but if a woman warns a man that she does not mean to join in the diversion, it is considered as an avowal of pregnancy, and she passes without molestation.

In the Birman empire, funerals are solemnized with great parade, and various external demonstrations of grief. The corpse is placed on a bier, and carried on men's shoulders; the procession moves slowly along; the relations attend in mourning; and women, hired for the occasion, precede the body, and chaunt a dirge-like air. The Birmans burn their dead, unless the person is a pauper; in which case, he is either buried, or cast into the river, as the ceremony of burning is very expensive. The bier is placed on a funeral pile six or eight feet high, made of billets of dried wood laid across each other, with intervals to admit a due circulation of air, and to increase the flame. The priests walk round the pile, reciting prayers to Godama, until the fire reaches the body, when the whole is quickly reduced to ashes. The bones are afterwards collected and deposited in a grave. Persons of high rank, such as the chief ecclesiastic of a province, the prime minister, or a member of the royal family, are embalmed, and their remains are preserved for six weeks, or two months, after which they are committed to the funeral pile. During this period the body lies in state in some monastery; but at the capital it is placed in a sacred saloon, beautifully ornamented with gilding, and exclusively appropriated to this purpose. Honey is said to be the principal ingredient which they employ to preserve the body from putrefaction.

Besides the Birmans, Col. Symes mentions a singular description of people called Carayners, who inhabit different parts of the country, particularly the western provinces of Dalla and Bassien, and of whom there are several societies in the districts adjacent to Raugoon. They were represented to him by a Catholic missionary as a simple, innocent race, mild in their manners, exceedingly hospitable to strangers, speaking a language distinct from that of the Birmans, and entertaining rude notions of religion. They are the most industrious subjects of the state, and raise a great part of the provisions used in the country. Agriculture, gardening, and the care of cattle, are almost their only occupations. Their villages form a select community, from which they exclude all other people; and they never reside in cities, intermingle, or marry with strangers. They profess and strictly observe the principle of universal peace, not engaging in war, or taking part in contests for dominion; a system which necessarily places them in subjection to the ruling power of the day. Of late years, however, they have been much oppressed by the great Birman landholders; in consequence of which, numbers of them have withdrawn into the mountains of Arracan.

In literature the Birmans have made considerable progress; for though they have not explored the depths of science, or reached to superior excellence in the fine arts, yet, in general, they are certainly an intelligent people. The knowledge of letters is so widely diffused among them, that there are no mechanics, few of the peasantry, or even of the common watermen, who can

not read and write the vulgar tongue. Few, however, are versant in their books of science, which, containing many Sanscrit terms, and being often written in the Pali text, are above the comprehension of the multitude. The Birman language contains thirty-three simple sounds, to represent which, the alphabet consists of an equal number of distinct characters, exclusive of various marks and contractions, which supply the place of long and short vowels, diphthongs, &c. The Birman write like Europeans, from the left to the right; and, though they leave no distinguishing place between their words, they mark the pauses of a full sentence, and the full stops. Their letters are distinct, and their manuscripts are, in general, very beautiful. The common books of the Birman, like those of the Hindoos, are composed of the palm-leaf, on which the letters are engraved with a style; but they are much superior to those of the Western continent, in the neatness of the execution, and in the ornaments which decorate them. Books, in the Pali text, are sometimes composed of thin stripes of bamboo, delicately plaited and varnished over in such a manner as to form a smooth and hard surface, on a leaf of any dimensions. This surface is afterwards gilded, and the sacred letters are traced upon it in black and shining japan: the margin is illuminated by wreaths and figures of gold, or a red, green, or black ground. In every monastery there is a repository of books, which are usually kept in lacquered chests. When at the capital, Colonel Symes paid a visit to the royal library, of which he gives us the following interesting description. "It is," says he, "a large brick building, raised on a terrace, and covered by a roof of a very compound structure. It consists of one square room, with an enclosed virando, or gallery, surrounding it. The room was locked, and, as we had not a special order for seeing it, the person who had the care of the library said, that he was not at liberty to open the doors, but assured us there was nothing in the inside different from what we might see in the virando, where a number of large chests, curiously ornamented with gilding and japan, were ranged in regular order against the wall. I counted fifty; but there were many more, probably not less than a hundred. The books were regularly classed, and the contents of each chest were written in gold letters on the lid. The librarian opened two, and shewed me some very beautiful writing, on thin leaves of ivory, the margins of which were ornamented with flowers of gold, neatly executed. I saw also some books written in the ancient Pali, the religious text. Every thing seemed to be arranged with perfect regularity; and I was informed that there were books on divers subjects; more on divinity than any other: but history, music, medicine, painting, and romance, had their separate treatises. The volumes were disposed under distinct heads, regularly numbered; and if all the other chests were as well filled as those that were submitted to our inspection, it is not improbable, that his Birman majesty may possess a more numerous library than any potentate from the banks of the Danube to the borders of China."

To this general account of the literature of the Birman, we may add a few particulars relative to some of the arts and sciences. They are said to possess many historical works, containing an account of the lives and actions of the different families of their princes; but they are very fabulous, and abound with omens and prodigies. They have also translations of the history of China and Siam, and of the kingdoms of Kathee, Ko-shampyee, Pa-

goo, Saymmay, and Layuzayu. In *medicine*, the Birman have several books. They divide diseases into ninety-six genera; and of these several are subdivided into many species. They are acquainted with the use of mercury in the cure of the venereal disease; but the manner in which they employ it is neither safe nor certain. They make a candle of cinnabar and some other materials, and, setting fire to it, the patient inhales the fumes with his nostrils; but he is seldom able to persevere long in this course, as it always produces a want of appetite, and extreme languor. Of the animal kingdom, mummy is a favourite medicine; but the greater part of the Birman remedies are taken from the vegetable creation, especially those of an aromatic nature. They are well acquainted with the plants of the country; and for a great number of them have appropriate names. On the whole, however, the practice of their physicians is almost entirely empirical; and, accordingly, they are not held in high estimation among their countrymen. There is a curious custom, mentioned by Dr Buchanan, with regard to this class of men. If a young woman appears to be dangerously ill, the physician and her parents frequently enter into an agreement, by which he undertakes to cure her. If the doctor is successful in this he takes her as his property; but if she dies, he pays a certain sum for her to the parents: for in the Birman empire no parent gives away his daughter, either as a wife or concubine, without some valuable consideration. In *surgery*, the skill of the Birman extends only to the dressing of wounds and setting of bones. Of late, indeed, they have introduced from Arracan the art of inoculation for the small-pox. The practice, however, does not appear to have become general, as a very great proportion of the people are marked by that disease. The Baptists, who have for some years laboured with so much success in propagating Christianity in Bengal, have lately sent a mission to the Birman empire; and, in 1808, one of the missionaries, Mr Felix Carey, introduced the vaccine inoculation into the city of Rangoon. He performed the operation on a considerable number of people, and, among others, the family of the governor, so that we fondly hope, this inestimable discovery will soon extend through the empire, and prevent the future ravages of the natural pox. On *law* the Birman have many treatises, particularly the Institutes of Menu, and copious commentaries upon them. The code in common use is said to have suffered several alterations and additions by the decrees of various princes. The king who sat on the throne when the British embassy was sent to this country, was a very intelligent prince, and had caused the Institutes of Menu to be translated from the English of Sir W. Jones. He must therefore have heard of what is pursued among the Europeans, at least in oriental literature; and we may hope that some more useful books may attract his notice, and promote the diffusion of knowledge among his people. The Birman are extremely fond of poetry and music. They have epic as well as religious poems, of high celebrity; and they are fond of reciting, in heroic numbers, the exploits of their kings and generals. It is said, that the prowess of the great Alompra, the deliverer of his country, is celebrated in verses not unworthy of his courage and his fortune. The members of the British embassy saw one of their dramatic representations at Pegu, and gave it considerable praise. The dialogue was spirited, without rant; the action animated, without being extravagant; and the dresses of the principal performers

were showy, yet becoming. Music is a science which is also held in considerable estimation throughout the Birman empire, and is cultivated more generally than in India.

The manner in which the Birmans divide time, is at once a proof of the progress and the defect of their knowledge. The space in which the finger can be raised and depressed, is called *charazi*; ten of them make one *fiiaan*; and six paaans one *fiizana*, or about a minute. The day commences at noon, and is divided into eight portions, of about three hours each. Their divisions of time are ascertained by a machine resembling the hour-glass, and sometimes by a perforated pan placed in a tub of water. They are announced by a stroke on an oblong drum, which is always placed near the dwelling of the chief magistrate of the town or village. It is commonly raised on a high bamboo stage, with a roof of mats to protect it from the weather. The edifice at the royal palace in the capital is of masonry, and is very lofty; so that the sound is said to be distinctly conveyed to the remotest parts of the city. The Birman year is divided into twelve months, which consist alternately of 29 and 30 days; so that an ordinary year consists only of 354 days. In order, therefore, to complete a solar revolution, they intercalate every third year a month of 30 days; and in that year they add other three days to certain of the months: but, as every fourth year will still occasion the difference of a day, as in our bissextile year, their style has been frequently altered by arbitrary authority. His present Birman majesty, however, is so desirous to ascertain and establish, by accurate tables, a permanent and invariable measurement of time, that he made application to the governor general of India to send to his capital a Bramin skilled in astronomy, to assist the deliberations of his council of professors, among whom his majesty always presides in person; and he is said to be no inconsiderable proficient in the science of astronomy. The manner in which the Birman month is subdivided, is probably peculiar to this nation. Instead of reckoning the days progressively, from the commencement to the close of the month, they advance no farther than the full moon; from which they recede, by retrogressive enumeration, until the end of the month. The month is also subdivided into four weeks, of seven days each; and the eighth day of the increasing moon, the fifteenth or full moon, the eighth of the decreasing moon, and the last day of the moon, are set apart by the Birmans as sacred festivals. On these hebdominal holidays no public business is transacted, and mercantile engagements are suspended; and the strict observers of them take no sustenance between the rising and the setting of the sun: but the latter instance of self denial is not very common, and is rarely practised, except in the metropolis, when the appearance of sanctity is sometimes assumed by the crafty as the means of attaining promotion. The sovereign himself is a great favourer of the austerities of the Birman religion; and his chief minister has for many years, on the Birman sabbath, abstained from food, so long as the sun appeared above the horizon.

With regard to religion, the Birmans are worshippers of Buddha; but the image which represents him is usually called Godama. The followers of this deity contend with the disciples of Brahma for the honour of antiquity; and they are certainly much more numerous, as his worship is prevalent not only in Ceylon, but over all the countries between Bengal and China. The Bir-

mans acknowledge, that they originally received their religion from Ceylon, where it exists in the greatest purity. Some time ago, a catholic bishop, residing at Ava, asked the chief Rahaan, called Zaradobeira, to give him some short treatise, which would explain the doctrines of Godama. The priest, willing to satisfy the bishop, wrote for his use a small treatise, the most important particulars of which are contained in the following abstract: "The gods who have appeared in the present world, and who have obtained the perfect state, *Niebau*, (deliverance from all the evils of life,) are four; Chau-chasam, Gonagom, Gaspa, and Godama. Of these the law of Godama ought at present to be followed.

"Q. Where is the god Godama? A. Godama, at the age of thirty-five years, having attained divinity, preached his law for forty-five years, and brought salvation to all living beings. At eighty years of age, he attained *Niebau*; and this happened 2362 years ago. Then Godama said, 'Alter I shall have departed from this earth, I will preserve my law and disciples for 5000 years; and he commanded, that his images and relics should be worshipped, which has accordingly been ever since done.'

"Q. What is the doctrine and law which Godama delivered to be observed by all men? A. It consists chiefly in observing the five commandments, and in abstaining from the ten sins.

"Q. What are the five commandments? A. 1. From the meanest insect, up to man, thou shalt kill no animal whatsoever. 2. Thou shalt not steal. 3. Thou shalt not violate the wife or concubine of another. 4. Thou shalt tell nothing false. 5. Thou shalt drink neither wine, nor any thing that will intoxicate: Thou shalt not eat opium, nor other inebriating drug. Whoever keeps these five commandments, during all successive transmigrations, shall either be born a nobleman or *nost*, and shall not be liable to poverty, nor to other misfortunes and calamities.

"Q. What are the ten sins. A. 1. The killing of animals. 2. Theft. 3. Adultery. 4. Falsehood. 5. Discord. 6. Harsh and indignant language. 7. Idle and superfluous talk. 8. The coveting of your neighbour's goods. 9. Envy, and the desire of your neighbour's death or misfortune. 10. The following of the doctrine of false gods. He who abstains from these sins, is said to obtain *Sila*; and every one who observes *Sila*, in all successive transmigrations, will continually increase in virtue, till, at length, he will become worthy of beholding a God, and of hearing his great voice; and thus he will obtain *Niebau*, and be exempted from the four known miseries, namely, weight, old age, disease, and death. We must also believe that Godama taught, if we observe his laws, we shall see the other gods, who are to arise after him.

"Q. Besides these already mentioned, are there any other good works which ought to be practised? A. There are. One good work is called *Dana*, which consists in giving alms, particularly to the Rahaans. A second is called *Bavana*, which consists in thoughtfully pronouncing these three words, *Aneizza*, *Docha*, and *Anatta*. By the word *Aneizza*, is understood, that he who pronounces it recollects, that, by his particular situation, he is liable to vicissitudes; by the word *Docha* is understood, that by the same situation he is liable to misfortune; and by the word *Anatta*, that it is not in his power to exempt himself from being liable to changes and to misfortune. Whoever dies without having observed the *Sila*, *Dana*, and *Bavana*, will certainly pass

into one of the infernal states, and will become a *Nirca*, a *Prietta*, or some animal.

“Revolving these things in your mind, O ye English, Dutch, Arminians, and others, adore Godama the true god; adore also his law and his priests: Be solicitous in giving alms, in the observance of *Sila*, and in performing *Bavana*. But a true and legitimate priest of Godama is not to be found, except in this empire, or in the Island of Ceylon; and you, O Bishop, have obtained a great lot, who have been thought worthy, although born in one of the small islands depending on *Zabudiba*, to come hither and to hear the truth of the divine law. This book, which I now give you, is more estimable than gold or silver, than diamonds and precious stones; and I exhort all English, Dutch, Arminians, and others, faithfully to transcribe its contents, and diligently to act according to the precepts therein contained.”

All the priests of Godama are properly what in a Roman Catholic country would be called regulars. There are no secular priests in this country who officiate in the worship of the people. These Rahaans, as they are styled, live together in convents, which are by far the best habitations in the empire. They are dressed in a long cloak of a yellow colour; like the Carmelites, they go barefooted, and have their heads close shaven, on which they never wear any covering: they all profess celibacy, and to abstain from every sensual indulgence. If a Rahaan is detected in an act of incontinence, he is expelled from the society, and subjected to public disgrace. The delinquent is seated on an ass, and his face daubed with black paint, interspersed with spots of white. He is thus led through the streets, with a drum beating before him, and is afterwards turned out of the city. Dr Buchanan informs us, that, as far as he could judge, the priests are very decent in their lives, remarkably hospitable to strangers, the most intelligent men in the country, and very highly respected by the inhabitants. The road, on all occasions, is yielded up to them; they are almost always addressed by some honourable title, and in their convents they are allowed the use of painting and gilding, which are prohibited to all other subjects. In some cases, they are even permitted to plaster the outside roofs of their habitations white, which is the royal colour, the most distinguishing of all royal insignia, and common only to Godama and the king. However, though they are so highly honoured, they retain the greatest simplicity in their manners. The Rahaans never dress their own victuals, considering it as an abuse of time to perform any of the common functions of life, which, so long as they occupy attention, must divert their minds from the abstract contemplation of the divine essence. They receive contributions of food from the laity, and prefer what is cold to hot. Each convent sends forth a certain number of its members, who walk at a quick pace through the streets, carrying a box in which the donations are deposited. During their walks they never cast their eyes around them, but keep them fixed on the ground; they do not stop to solicit, and seldom even look at the donors, who appear more desirous to bestow than they are to receive. The Rahaans eat only once a-day, namely, at the hour of noon; and as a much larger quantity of provisions is commonly procured than is sufficient for the members of the convents, the surplus is disposed of to needy strangers, or the poor scholars, who daily attend them for instruction in letters, and in the duties of religion and morality. From the number of convents in the neighbourhood of Raugoon, the

number of priests must be very considerable. Colonel Symes was informed they exceeded 1500; but this must include those in their noviciate. Formerly, it is said, there were also nunneries of virgin priestesses, who, like the Rahaans, wore yellow garments, cut off their hair, and devoted themselves to chastity and religion; but these societies were long ago abolished, as injurious to the population of the state.

The temples of Godama are generally of a pyramidal form, and are supposed to contain some relics of the god, as a tooth, a bone, a hair, or a garment. The pyramids are often of an immense size; they are constructed of solid brick-work, plastered over, and generally placed on a prodigious elevated terrace. The base of the pyramid is frequently surrounded by a double row of small ones; and the summit of the whole is always crowned with umbrellas, made of a combination of iron bars, into a kind of fillagree work, and adorned with bells. Many of these pyramids are from three to five hundred feet high. In the larger temples, the umbrella, with at least the upper part of the pyramid, and often the whole, is entirely gilded over. Other temples, of nearly a similar structure, but hollow within, contain images of Godama, to which the adoration of his disciples is directed; however, the greater number of the images are placed in a kind of chapeis which surround the large pyramids, containing the relics of Godama. In these figures, the god is always represented as a young man, of a placid countenance, and generally in the dress of a Rahaan. His postures are various. The most common is that of sitting cross-legged upon a throne, with his left hand resting upon his leg, and holding a book, and with his right hand over his knee. The images of Godama, are of various materials, as clay, copper, silver, and alabaster. Many of them are completely gilded and ornamented with paintings of flowers. The size also of these images varies exceedingly. Some are not above six inches high, and others are of a most colossal stature. Dr Buchanan mentions, that he saw an image at Ava, consisting of one solid block of pure alabaster, and in a sitting posture. He had no opportunity of measuring its dimensions; but its fingers appeared to be about the length and thickness of a large man's thigh and leg, from whence some idea may be formed of the immensity of the whole.

Besides attending to their private devotions, it is customary among the Birmans to present offerings at the temples. These are very various; boiled rice, fruits, especially the cocoa nut, flowers natural and artificial, and a variety of curious figures, made of paper, gold leaf, and the cuttings of the cocoa nut kernel, are the most common. It is also very customary for the rich to offer elegant white umbrellas with golden ornaments, large slippers, canes, pillows, and all manner of utensils gilded, and of the finest materials. Instead of these costly offerings, the poor content themselves with presenting imitations of them in paper. These gifts are placed on altars, or on wooden benches, before the god or the temple; and the eatables become a prey to the dogs or the crows. People who have been in danger by water, present models of boats or ships, some of which are formed with considerable neatness. One of the most common ways for a person to express his devotion, is to gild a patch of a temple, in consequence of which many of them have a very motley appearance. The munificence of the king in this respect has been very extensive. Dr Buchanan was told, that he is annually at the

expense of nearly 86,805lb. weight of silver for this purpose. In no case do the Birmans offer bloody sacrifices.

In the Birman empire, the most liberal toleration of religion prevails. In the same street may be heard the solemn voice of the Muezzin calling the Islamite to early prayers, and the bell of the Portuguese chapel tinkling a summons to the catholic Christian. Processions meet and pass each other without giving or receiving the smallest offence. The Birmans never trouble themselves about the religious opinions of any sect, nor disturb their ritual ceremonies, provided they do not interfere with the peace of society, or meddle with their own deity Godama. Some few of the natives have embraced the catholic religion, but it does not appear that any persecution has been excited on this account. The catholics have three places of worship at Raugoon, but the congregations are not very large. In no capacity can any one reside in the Birman empire with less suspicion than as a teacher of religion. Persons sustaining this character, whether Christian, Mahomedan, or Pagan, have greater privileges by order of government than those in any other capacity.

In this country the form of government is despotic; but still the emperor is accustomed to consult a council of ancient nobles. There is no country of the East in which the royal establishment is arranged with such minute attention as in the Birman court; it is splendid without being wasteful, and numerous without confusion. There are different officers by whom the affairs of government in its various departments are transacted. The Birman government has no hereditary dignities or employments; for on the death of the possessor, all honours and offices revert to the crown. The order of nobility has different degrees, which are distinguished by the number of strings which compose the chain which is the badge of the order. No subject is ever honoured with a higher degree than 12, and the king alone wears 24.

The Birman system of jurisprudence is replete with sound morality, and is distinguished above the Hindoo code by its perspicuity and good sense. It provides especially for almost every kind of crime that can be committed, and adds an ample chapter of precedents and decisions to guide the inexperienced in cases of doubt and difficulty. The trial by ordeal, however, is disgraceful to this code; but it prevails in all countries where the Hindoo religion is professed, and is as ancient as their records. An instance of the exercise of this mode of trial is mentioned by colonel Symes. Two women having litigated a small property in a court of justice, and the judges finding it difficult to decide the question of right, it was agreed to refer the matter to the issue of an ordeal. The parties, attended by the officers of the court, the Rahaans, and a multitude of people, repaired to a pond. After certain prayers and ceremonies, the two women entered the pond accompanied by two or three men, one of whom placed them close to each other, and put a board on their heads, which he pressed down till they were both immersed at the same instant. After continuing out of sight for about a minute and a half, one of them being nearly suffocated, raised her head, whilst the other continued to sit on her hams at the bottom, but was immediately lifted up by the man; after which, an officer of the court pronounced judgment in her favour; and of the equity of the decision, none present seemed to entertain the smallest doubt. This practice, however, and that of imprecation,

are now losing ground, and have of late years been discontinued by the judicial courts both of India and of Ava. The criminal jurisprudence of the Birmans is lenient in particular cases, but rigorous in others. The first commission of theft does not incur the penalty of death unless the amount stolen is above 800 tackals, or about 100*l.* sterling, or is attended with some circumstances of atrocity, as murder or mutilation. In the former case, the culprit has a round mark imprinted on each cheek by gunpowder and puncturation, and on his breast the word *thief*, with the article *stolen*; for the second offence he is deprived of an arm; but the third inevitably produces capital punishment. Decapitation is the mode by which criminals suffer, and in the performance of it the Birman executioners are exceedingly skilful. In the administration of public affairs, the Birman government does not allow of privacy or concealment. It is worthy of remark, that when the British ambassador had obtained from the emperor the establishment of certain regulations with regard to our commerce, and had returned to the port of Raugoon, the viceroy of that district informed him that the order would be publicly read and regulated on the following day, adding, that the records were also open to the public inspection, and that whosoever chose might at any time procure a copy, by paying a trifling fee to the officers of the court.

The punishments which thieves, and those who drink spirits, &c. meet with in this country, are very frequent and severe. Within a few days, the Baptist missionaries saw the punishment of beheading, of cutting off the legs, of crucifying, and of pouring boiling lead down the throat. In the *Oriental Star*, a Calcutta newspaper for Jan. 23, 1808, there is the following account by an English gentleman recently arrived from Raugoon. The viceroy of that city, whose son's head had been cut off at Ava for chewing opium, had, upon his arrival at the latter place, just before he landed, drawn his sword on board a boat, and thrown the scabbard into the river. His attendants remarking this extraordinary act, asked him the cause of it. His reply was, "my sword shall never be sheathed till it has revenged the death of my son." A man for chewing opium was put to death by crucifixion, in which red hot nails were used. In this position his belly was ript up, and in that horrid situation he was left to expire. His entrails lying at his feet, were immediately devoured by crows and vultures, several hours before the unhappy man ceased to breathe, and of which he seemed to be sensible. Another unhappy wretch for getting drunk, had hot lead poured down his throat in small quantities of about half a glassful: the two first caused a strong smoke to issue from his mouth, of which he was apparently sensible, but the third dose put an instant period to his existence. Another culprit for a similar crime was sentenced to be roasted alive, and the execution was to take place a few days after the writer's departure from Raugoon. Two others, one who had run away from the Birman army, and one whose father had also deserted, but who had not been taken, had their legs cut off above the knees, were also nailed up by their hands with red hot nails, and the hair of their heads tied fast up to a pole, and in this situation they were left to bleed to death. These miserable wretches remained alive for some hours, during which their piercing cries were distressing beyond expression, so that not an inhabitant in the place had any rest the whole night. The wives

and children of the latter unhappy sufferers were to be blown up three days after. It seems that the viceroy, who ordered these dreadful punishments, had, during a long administration, executed the duties of his office with the greatest mildness and benevolence, screening many offenders from the rigour of the barbarous law of the country; but the execution of his son by the court of Ava had driven him to the highest pitch of desperation, and caused him to vow, that the bloody criminal code of his country should be enforced to the utmost extremity.

The Birmans are a nation of soldiers; every man in the kingdom being liable to be called upon military service, and war is deemed the most honourable occupation. The regular military establishment of the nation, however, as among our ancestors in feudal times, is very inconsiderable, consisting only of the royal guards, and as many troops as are necessary to preserve the police of the capital. They are supposed to amount in all to about 2000 infantry and 300 cavalry; though it is said that the cavalry, scattered in small detachments through the districts adjoining to the capital, amount to 2000. The infantry are armed with muskets and sabres, and are not uniformly clothed; the cavalry seldom use any other weapon than a spear, about seven or eight feet long. When an army is to be raised, government issues a mandate to all the viceroys of provinces, and governors of districts, requiring a certain number of men to be at a general rendezvous on an appointed day; the levy is proportioned to the population of the province or district, according to the number of the registered houses that it contains; the provincial court determines the burden which each house is to bear; and a certain number of houses furnish a recruit among them, or pay 300 tackals, which is about 40*l.* or 45*l.* The families of their conscripts are carefully retained in their districts as hostages for the good conduct of their relation. In case of desertion or treachery, the innocent wife and parent of the guilty person are dragged to execution without pity; even cowardice subjects the family of the delinquent to capital punishment, a law which, however barbarous, is rigorously executed.

But the most respectable part of the Birman military force, is the establishment of war boats. These carry from 50 to 60 rowers, who use short oars that work on a spindle. The prow is solid, and is a flat surface, on which, when they go to war, a piece of ordnance is mounted; a six, a nine, or even a twelve pounder, and several are frequently fixed on the stern. Each rower is provided with a sword and lance, which are placed by his side while he plies the oars. Besides the boatmen, there are usually 50 soldiers on board, who are armed with muskets. Their attack is extremely impetuous; they advance with great rapidity, and sing a war song, at once to encourage their people, daunt their adversaries, and regulate the strokes of their oars. They generally endeavour to grapple, and when that is effected, the action becomes very severe. The largest of these war boats is from 80 to 100 feet long, and they draw only about three feet of water.

The revenue of the Birman empire arises from one-tenth of all the native produce, and of all foreign goods imported into the country. However, as grants to princes of the blood and provincial governors are made in provinces, cities, villages, and farms, the rent of which they collect on their own account, and as in consequence of this, money is seldom disbursed from the royal treas-

uries, the Birman sovereign must possess immense riches. See Symes' *Embassy to Ava*, 3 vols. *Asiatic Researches*, vol. v. p. 111, 143—156, 219—240; vol. vi. 127—136, 163—308. *Baptist Periodical Accounts*, vol. iii. p. 342, 343. Pinkerton's *Geography*, vol. ii. (w. b.)

BIRMINGHAM, a market town in the hundred of Hemmingford, and in the county of Warwick, is 116 miles from London by Oxford, and 109 by Coventry. It is about two miles in length, pleasantly situated on the side of a hill by the river Rea; and the soil, on which it is founded, consists chiefly of a dry reddish sand. It is remarkably free from damp; and even its cellars are described as comfortable habitations. Its air is naturally exceedingly pure; and, notwithstanding its close population, continual smoke, and noxious metallic effluvia, it is accounted by Dr Price one of the healthiest towns in England. From the register of burials, in an average of six years ending in 1801, while the scale of mortality in London was as 1 to 31, and in Manchester as 1 to 37, that of Birmingham was only as 1 to 59. Instances of longevity among its inhabitants are strikingly numerous; and every mean is employed for the preservation of health, particularly bathing, for which the most complete and extensive accommodation in the kingdom has been provided.

The antiquity of Birmingham is argued from the circumstance of its being contiguous to two Roman roads, the Ikenild and Shirley streets; and it is supposed to have existed as a town in the reign of king Alfred. It appears, at least, upon record, that, in 1251, William de Birmingham, lord of the manor, procured an additional charter from Edward III. reviving and granting several privileges. It was besieged by prince Rupert in 1643; and, being taken after a short resistance, was commanded to be burnt to the ground; but, by some favourable circumstance, the conflagration was confined to a few houses in Bull street. It suffered very severely from the plague in 1665; and after the churchyard was filled with the dead bodies, they were interred in an acre of land at Lady Wood green, which, from this circumstance, has received the name of Pest-ground. It had attained some degree of eminence previous to the reign of Charles II.; but it is from this period, that its rapid increase must be dated. About the year 1700 it did not contain above 30 streets, but now they amount nearly to 250. Its amazing progress may be rendered more apparent by the following statements. In 1779, there were only three houses between the roads to Wolverhampton and Dudley; in 1780, they increased to 55; in 1781, to 144; and, in 1791, there was an addition of 833. In 1688, the sum disbursed for the relief of the poor amounted to 308*l.*, 17*s.* 9½*d.*; but, in 1787, it was 12,429*l.*, 9*s.* 11½*d.*

The lower part of the town consists chiefly of old buildings, is filled with workshops and warehouses, and is inhabited principally by manufacturers. Almost every artist has a separate house, so that the population is spread over a great extent of surface, and free from many of the evils which prevail in those great towns where the habitations are larger, and several families crowded into one floor. The upper part of the town has a very superior appearance, consisting of new and regular streets, and containing a number of elegant buildings. There are two parish churches; St Martin's, with a lofty spire, usually denominated the old church, and situated in the lower part of the town, built originally of stone about the year 1300, cased with brick in

1690, and repaired, in 1786, at an expense of 4000*l.*: and St Philip's, or the new church, which is a very handsome structure, founded in the year 1711, built in a light elegant style, and capable of containing more than 2000 persons. It has a square tower adorned with a cupola, a peal of ten bells, and a clock with musical chimes. There are also four chapels in connection with the church of England; St Bartholomew's, erected in 1749; St Mary's, in 1774; St Paul's, in 1779; and the house of Dr Ash, a celebrated physician in Birmingham, which was converted into an elegant chapel by a private gentleman, at his own expense, in 1789. There is a number of dissenting places of worship: two presbyterian meeting-houses, and a third in contemplation; three of independents; three of baptists; several of the methodists; one of quakers; a Romish chapel, and a Jewish synagogue.

Birmingham is distinguished by a variety of charitable endowments. The free school, a very ancient institution, but the present building, a large and handsome edifice, with a neat tower in the centre, and a statue of Edward VI. in front, was erected in 1707; the blue coat school, established in 1724, which receives 150 boys, and 40 girls; the dissenters charity school, into which 40 boys and 20 girls are admitted; the workhouse, founded in 1733, which possesses a revenue of 17,000*l.*, raised from the inhabitants by an assessment of 6*d.* in the pound, and which affords relief to 7000 persons; the general hospital, erected in 1766, supported by voluntary contributions and many large bequests, which possesses an income of about 1000*l.* per annum, and which, upon an average, accommodates upwards of 70 patients weekly.

Among the public institutions of Birmingham may be mentioned the libraries, the first of which was founded in 1779, containing about 10,000 volumes, and supported by more than 500 subscribers; a museum in New street, the property of Mr J. Bisset, stored with a variety of natural and artificial curiosities; the bathing accommodations at Lady Well, where are 7 marble baths, provided at all times with hot or cold water, and particularly one appropriated for swimming, 36 yards by 18, situated in the centre of a garden, furnished with 24 recesses for undressing, and the whole surrounded with a high wall; the new theatre, built at an expense of 14,000*l.*, the front of which is of hewn stone, and to which a tavern and assembly room are annexed; Duddeston gardens, or Vauxhall, disposed upon a principle similar to those of London, for music and other entertainments; and the barracks, which occupy five acres of land, held by government at one penny per yard, and which accommodate 162 men.

Birmingham was never incorporated, and possesses no chartered privileges; but, in consequence of this circumstance, the industry of the place is not disturbed by election politics, and its magistrates, though without any borough influence, are not inferior in respectability to those of any city in the kingdom. They are chosen annually; and consist of a high bailiff, who inspects weights and measures; a low bailiff, who summons juries, and chooses the other officers; two constables, and one head borough; two high tasters, who examine the quality of the beer; two low tasters, who inspect the meat exposed to sale; and two leather sellers, whose offices are now merely nominal. A court of requests, established by act of Parliament in 1752, and consisting of 72 commissioners, three of whom make a quorum, meets every Friday morning; and the clerks, who attend to

give judicial assistance, are always practitioners of the common law.

But the most prominent feature in the town of Birmingham, and the most deserving of particular notice in every description of the place, is the amazing variety, extent, and excellence of its hardware productions. It may safely be pronounced to be the principal manufacturing town in the world; and stands unrivalled in the superior quality and cheapness of its commodities. The principal manufacture carried on by the people of Birmingham, in the earliest periods of its history, was the tanning of leather, and it continued for nearly 700 years to be a noted market for that article; but, towards the end of the last century, this branch of trade was so completely abandoned, that in 1795 there is said to have been only one tanner in the place. Before the Revolution, its other manufactures were confined to coarse iron wares; but the skill of its artists was brought into greater notice and exertion by the following circumstance. William III. having expressed his regret, that it should be necessary to import fire arms from foreign countries, Sir Richard Newdigate, member of Parliament for Warwickshire, engaged on the part of his constituents, to supply the demands of government; and an order, which was sent to Birmingham, having been speedily and satisfactorily executed, it has continued from that period to furnish the greatest proportion of muskets, swords, and other small arms. The button and buckle trade next became the most extensive; and in one shop, the former article has been known to be manufactured to the value of 800*l.* per week. Within the last century, every species of steel manufacture has been produced in the utmost abundance and perfection; and a very large street has received the name of Steelhouse lane, from the extensive works of this kind which it contains. There is a considerable whip manufactory and type foundry, and three extensive breweries of ale and porter.

Of late years, very great additions have been made to its trade and manufactures; and there would be no end to an enumeration of its multifarious productions. Among the principal articles, however, may be mentioned an immense variety of buttons, buckles, and snuff boxes; toys, trinkets, and jewellery; polished steel watch chains, cork screws, &c.; plated goods for the dining and tea table; japanned and enamelled articles; brass works of every description; swords and fire arms; medals, and coins of various sizes and metals; copying machines and pneumatic apparatuses; the more ponderous productions of the casting furnace and rolling mill; and, in short, every hardware commodity that can be considered as curious, useful, or ornamental. The manufactories established here for all these different articles are conducted upon the largest scale, and with the most astonishing ingenuity; but by far the most remarkable and extensive is that at Soho, above two miles from Birmingham, the property of Messrs Boulton and Watt, which deserves a more particular description than can be admitted in this place, and for which our readers are referred to the article Soho.

Among the various concurring causes, which have contributed to the extraordinary progress and prosperity of Birmingham may be mentioned, its convenient situation, almost in the centre of England; its proximity to the coal mines; its want of corporate restrictions; its freedom from election canvassings; and, particularly, its extensive canal communications. Formerly, its va-

rious and valuable goods were sent chiefly to London by land carriage, and supplied the foreign markets only through the medium of merchants in the metropolis; but now the principal orders for foreign supply come directly to mercantile houses in the town of Birmingham itself, and, by means of its improved inland navigations, its heaviest products are conveyed to the remotest distance without any considerable addition to their original price. By the old canal, which was cut in 1768 and 1769, are conveyed to this place various raw materials, and particularly the important article of fuel from the Wednesbury collieries. This cut was, in 1772, extended to Autherby, and thence to the Severn, by which there is a communication with Shrewsbury, Gloucester, and Bristol. In another direction it joins the Trent, and thus opens a conveyance to Gainsborough, Hull, and London. From this canal there is likewise a junction with the grand line of canal, which runs along the pottery in Staffordshire, thence extending to Manchester and Liverpool. By the new, or Birmingham and Fazely canal, there is a communication to Fisherwick, Tamworth, Polesworth, Atherstone, Nuneaton, Coventry, Oxford, and thence by the canal or the Thames, to London. Thus the produce of its manufactories are easily dispersed throughout the kingdom, and conveyed entirely by water carriage to the principal sea ports of the North Sea, the British Ocean, the Irish Sea, and St George's Channel. But, though the flourishing manufactures of Birmingham have filled the town and its vicinity with a multitude of ingenious and industrious inhabitants, all usefully employed in their own support, and in the service of the community, yet it must be admitted, that much ignorance, profligacy, drunkenness, and discontent prevails among the labouring classes, and that these have, on several occasions, exhibited a strong disposition to rioting and tumult. This was remarkably manifested in the year 1791, about the commencement of the revolution in France, when the most disorderly proceedings were carried on during several successive days, and property to the amount of 60,000*l.* was plundered or destroyed.

In 1801, the town of Birmingham contained 16,403 houses, of which 1875 were uninhabited; and its whole population amounted to 73,670, of whom 62,702 were employed in trade and manufactures. See Hutton's *History of Birmingham*. (i)

BIRR, or **PARSONS TOWN**, the name of a post and market town in King's county, Ireland, situated on the river Little Brosna. It carries on a considerable manufacture of cloth and serges, and has also several breweries, distilleries, and maltings. See Coote's *Survey of King's County*. (j)

BIRSE, the name of a river in Switzerland, famous for the desperate battle fought near it in 1447, when the French triumphed by the force of numbers, over the matchless heroism of the Swiss. An account of this battle will be found in Coxe's *Travels in Switzerland*, letter 17, vol. i. p. 177. See also **SWITZERLAND**. (k)

BIRTH. See **MIDWIFERY**.

BISCARA, or **BISCARIS**, or **BASCARA**, a town in the kingdom of Algiers, originally built by the Romans, and afterwards destroyed by the Arabs, by whom it was since rebuilt. Its paltry castle, defended by six pieces of ordnance, is the seat of a Turkish garrison. The numbers of scorpions and poisonous reptiles that infest the houses, drive the inhabitants from the town during summer. The highest class of the inhabitants carry on a

little trade in negroes and ostrich feathers, while the lower orders emigrate to Algiers, to seek for subsistence from the most menial occupations in that metropolis. They are held in great estimation for their honesty and kindness; and when they have amassed a little money, they return to Biscara, where they are reckoned among the wealthy of that place. E. Long. 5° 15', N. Lat. 34° 30'. (l)

BISCAY. Part of the Spanish monarchy, including three cantons, Alaba or Alava, Guipuzcoa, and Biscay Proper, constitute a province called the Lordship of Biscay. This province is bounded by the Bay of Biscay, and the Gulf of Gascony, on the north; on the east, by Navarre; on the south, by Old Castile; and on the west, by the same kingdom and the Asturias. The country consists entirely of hills and mountains, many of which are piled on each other to a great height: the ascent of the mountain Gorveya occupies five hours; but on the summit is a beautiful plain, whither the herds of Biscay Proper and Alava are sent to pasture during several months of the year: some of the hills are cultivated to the top; and the vallies dividing them being devoted to agriculture also, and the pasture of flocks, the inhabitants suffer few of the inconveniences attached to a mountainous country.

Different species of iron ore are found in the mountains of Biscay; the richest is near Hernani in Guipuzcoa; in the vicinity of Bilboa, the chief town, where the ore reaches the surface of the earth, and at Somorrostro likewise in Biscay Proper. The last consists of a regular undulated hill, which may be encompassed in walking during four or five hours; and here the ore forms an uninterrupted stratum from three to ten feet in thickness, covered with a bed of whitish calcareous rock from two to six feet thick. When first taken from the mine, the ore is of the colour of bull's blood, and exhibits a purple tinge on being wet. It is reputed the softest and most fusible iron ore of all Europe, and is said to be frequently mixed with what yields a harder metal in smelting, by those who carry it to a distance from the mine. To reduce the ore to a malleable state, it is first roasted by alternate strata of wood and ore piled together being set on fire; next it is put into a furnace, and after having been in a state of fusion, it is placed on an anvil, under an immense hammer of 700 or 1000 pounds weight, by which the mass is squared and reduced to bars. Thus the ore is said to be fused in a few hours, the bars formed, and sold to blacksmiths. A quintal of ore will afford thirty-five pounds of good iron. The mine of Somorrostro has been worked during many centuries; and the workmen employed in it, from frequently finding broken pieces of implements that had been used to dig it out in ancient times, maintain that the ore is renewed. Besides the mine of Somorrostro, there is a great ferruginous rock, about half a mile from Bilboa, which is of a different nature. An engineer engaged in some public works near this rock, found a vein of ore eighty feet from the surface, consisting of an infinite variety of ramifications, some an inch in diameter, and others as thick as the arm. Hæmatites or blood-stones, are often found in the mines of Biscay, which yield twice or thrice as much iron in proportion as comes from the ore of Somorrostro, but hard and brittle. About a league from the town of Mondragon, in Guipuzcoa, is the iron mine of Mondragon, the ore of which affords about forty per cent. of metal. It is of difficult fusion, and is said to contain natural steel. Tradition affirms, that the famous

Toledo sword-blades were made of the iron of Mondragon, and that they were tempered only during winter. Others insist that they were fabricated of the pure steel found there, to which some iron was added in the middle of the blade, to render it more flexible: It is likewise reported, that the name *Pedro de Lagareta of Bilbao* proves that a blade is genuine. Copper and marble are found in Biscay. A salt spring near the village of Aguarda produces a great quantity of salt, which is extracted by boiling and evaporation: and there are various mineral waters, both hot and cold, in all the three cantons; though their constituent principles, from never having been analysed, are unknown. Near the village of Llodio, between Bilbao and Orduna, is a well, apparently communicating with the sea, which is seven leagues distant. When the tide flows, the water in the well rises, and as it ebbs, it falls. Besides this periodical rise, the well becomes still fuller, and even overflows in a storm, when it crosses a neighbouring road, and is hot and soapy.

The mountains of Biscay are beautiful and picturesque; many of them are covered with trees and shrubs of natural growth, such as the oak, strawberry, and currant, indigenous to the climate; and the inhabitants of the province have contributed to render them still more woody, by the plantation of fruit trees, and those which afford useful timber. The immense waste of fuel in the iron works of the province render this a necessary precaution; and, were it not for the constant renewal of wood, the mountains would in a few years be stripped bare.

Wild boars still exist in the woods of Biscay, and lynxes have been killed in their immediate vicinity. Wolves sometimes appear, and foxes are extremely noxious to the animals they can overpower.

Five species of birds of passage annually enter Spain from Africa, when the heat of the season forces them to change their abode. Those called *chimbos*, on the failure of fruit, by being burnt up, and of ants their principal sustenance retreating from the scorching rays of the sun, cross the Straits, and entering Andalusia, distribute themselves in flocks over all Spain. The *chimbos* breed in Andalusia and the Sierra Morena, and remain there among the copses, which they particularly inhabit, feeding on fruit and ants; but when these fail, they take a rapid flight over the plains of La Mancha, and arrive in Biscay during August, where great numbers are caught and brought to the public markets. Though lean, feeble, and exhausted with the length of flight, in the space of four days they become as fat as ortolans or beccafigos. The *chimbos* again shift their abode, when the autumnal rains occasion the failure of their necessary food, and then they disappear in a single night. An instance is related of a great multitude of them having collected on the 27th of September, when a fresh breeze sprung up, and next day not one was to be seen: they disappeared as if anticipating heavy rains, which began to fall on the 29th. The *chimbos* are succeeded by wood-cocks, which breed among the rocks on the north parts of the mountain Gorveya.

The population of Biscay is limited in proportion to the extent of territory, for the whole lordship does not contain above 300,000 souls. According to the royal census in 1787, 1788, the population was 310,758, of which 116,042 belonged to Biscay Proper; but from a more recent enumeration in 1800, the population, even including a district which is generally esteemed without its confines, had decreased 20,000. One portion of the

population was divided into 2084 priests, 2043 monks and nuns, 116,923 nobles, 471 persons in the law department, 455 students, and 8731 servants.

The territory contains 720 parishes, in which are 158 religious houses, 4 cities, 176 towns, and 446 villages. The chief towns are, Bilbao in Biscay Proper, Vittoria in Alava, and St Sebastian in Guipuzcoa. The first is situated on the banks of the river Ybaizabal, about two leagues from the sea; and being a port, which in former days was proverbially the terror of British seamen, carries on a considerable trade. This would be greatly increased, were it not for injudicious regulations, by which it is rather discouraged than otherwise. Owing to the inhabitants resisting the introduction of custom-houses among them, they are deprived of free commerce with America; and whoever wishes to engage in an adventure thither, must prepare it in another port beyond the province. The settlement of strangers in the town is likewise subject to difficulties; for, to obtain the freedom of it, one must prove that he is not descended from a Moor or a Jew; that he is sprung of a noble family; at least that he has not exercised any mean or mechanic art. Commissioners are actually charged with investigating these particulars; a proceeding so repulsive to the encouragement of liberal traffic, that it can excite no surprise if it should never flourish. An uncommon degree of dampness prevails in Bilbao, by which iron is covered with rust; furniture, even in the upper apartments, injured; the salt extracted out of dried fish; and, as some suppose, the multiplication of destructive insects promoted. Yet few diseases prevail, and the inhabitants enjoy health and strength, a cheerful disposition, and longevity. It has thence been asked, "Why should Bilbao, built on the side of a river, in such a damp situation, and chiefly on piles, like the cities in Holland, be so remarkably healthy, when every thing should conspire to render it the reverse?" The solution of the difficulty has been traced to the constant breezes, which prevent any accumulation of vapour, and that stagnation of it, which is pestiferous to animated existence. During four months that Don Guillermo Bowles resided there, only nine persons were buried, four of whom were above eighty. Vittoria, which is situated on the declivity of a hill, contains 6000 or 7000 inhabitants; its population is said to have been anciently 18,000. Here there is a royal asylum for 150 persons, and six monasteries and numeries. St Sebastian lies on a peninsula, flanked with batteries, and protected by a castle on a naked circular hill; but, notwithstanding the appearance of strength, it could not make a protracted resistance. Owing to this town being a sea port, and carrying on some trade, the population rises to 13,000 souls. Most of the other towns in Biscay are inconsiderable. Fontarabia, on the extreme limits of Spain, was formerly esteemed one of the keys to the kingdom, and once stood a siege by the French.

The Biscayans convert the vallies, and the less rugged parts of their mountains, to the greatest agricultural use of which they are susceptible. But the farmer has to contend with a stubborn soil, which only by the unsparing use of manure affords him an abundant harvest. For centuries the fields have been plentifully supplied with lime, yet little alteration in many instances follows; and, were it not for extraordinary exertion, nothing except brush-wood and briars would spring. The mode of turning up the earth, which is detailed by the acute and intelligent Bowles, is extremely rude and

laborious. An iron-pronged instrument is forced into the ground by the united power of three or four persons, and large pieces of turf turned over by mere manual power. These are afterwards broken in pieces, and the clods beaten with wooden mallets: holes are dug, and the grain sown in them. The steepness of the mountains, added to the stubbornness of the soil, is a great obstacle to agriculture, insomuch, that the consumption of the lordship exceeds its produce; and the income from land, deducting all charges, amounts to no more than two *per cent.* There is abundance of good fruit in Biscay, and wine is made for home consumption. An indifferent kind, called Chacoli, is procured from a mixture of grapes, and until it is consumed, no other kind can be sold by the vintners. The proprietors being thus secure of a market, become regardless of its quality, and it is carelessly made; it serves, however, only during four months of the year, and the remainder of what is required for the lordship comes from Old Castile. Vineyards are numerous about Bilbao and Orduna, forming the principal revenues of the gentlemen.

The number of iron mines in Biscay has led to the establishment of extensive manufactories, particularly as the ore may be procured at a trifling expense. The mine of Somorrostro is free to the whole inhabitants; it is common property and each may carry away as much as he pleases. Great quantities are conveyed from it by water-carriage; and calculations have been made, that it does not yield less than 800,000 quintals annually. There are manufactories of anchors, cannon, and other fire arms, in different parts of the province. Copper boilers of large dimensions are fabricated at Toledo, one of the chief towns of Guipuzcoa, and sheets of sheathing copper prepared at Balmuseda. Extensive manufactories of cordage and rigging are likewise established at St Sebastian and Bilbao.

The only natural productions with which Biscay can supply other countries, are iron and chesnuts. Notwithstanding the abundance of the former, the profits to the proprietors are extremely inconsiderable. A well managed forge does not produce above 500 ducats, each worth 4s. 8d. to its owner; and the returns of some, after paying all expenses, scarcely amount to 500. Yet this is the chief article which brings money into Biscay. But the inhabitants are obliged to be economical of fuel, and to use small forges. Were these as large as some which are employed in the great iron works in other parts of Europe, the mountains would be stripped bare of wood, and the works interrupted for want of fuel. The preservation of ancient privileges checks the trade of Biscay; for Bilbao, owing to the rejection of custom-houses, receives no encouragement from government. A commercial company, established at St Sebastian in 1728, proved of great utility to the province: Spain immediately supplied all Europe with cocoa, at a period when tea was only beginning to be known, and it quickly fell two-thirds in price. Subsequent mismanagement, and the contraction of a great load of debt, occasioned the dissolution of the company in 1780; but, until the present war, a private trade with America was still carried on by the merchants of St Sebastian. The intercourse of the province within its own limits, and also with other parts of Spain, is greatly facilitated by excellent roads, though there is a great want of inns. Formerly the roads passed over mountains, or along the edge of precipices, and, in consequence of the incon-

venience attending them, the three cantons united to form new ones at the public expense.

A society was established a considerable time ago, called the *Sociedad Bascongada*, or Biscay Society, partly, we believe, with the view of philosophical improvements; but there are here no extensive seminaries of literature. A school was established on a liberal plan at Vergara, in Guipuzcoa, solely at the expense of a patriotic society, where various branches of useful study were taught. There are sixteen masters, who, in addition to the more ordinary parts of education, teach the French and English languages, drawing, and music. The institution is under the superintendance of commissioners, who are changed every four months; and one of them constantly resides in the edifice devoted to its purposes. Every four months, also, the pupils undergo a public examination in presence of the commissioners, and prizes are annually bestowed on the most meritorious. Naval schools have been established in Biscay, and schools for drawing at Vittoria.

Biscay can boast of few learned men. Larrea, a celebrated lawyer, who flourished in the seventeenth century, was born at Vittoria; and in that preceding it, Diego Esquivel wrote a work on the reformation of religion, which is said to contain many excellent principles, though esteemed too difficult to be converted to practice. The language of the province is distinct from that spoken in the rest of the Spanish dominions, and its use remounts to a high period of antiquity. It is said to be soft, harmonious, and energetic, and so peculiar to the inhabitants, that Larramendi wrote a book called *El imposible vencido; arte de la lengua Basconada*: and the common Spanish dialect is not understood in the mountains.

The Biscayans possess an inherent love of liberty, which nothing can prompt them to forego; they jealously preserve various privileges, which they either enjoyed while an independent government, or obtained after becoming a province of Spain. Their taxations, instead of being duties imposed by the crown, consist of voluntary contributions advanced by the inhabitants themselves. No stamped paper, which is one great source of revenue, is received in the lordship; and some articles, such as tobacco, which are elsewhere the subject of royal monopoly, are open to the traffic of each individual. Biscay is not liable to the impress of seamen; it is exempt from furnishing any quota in a levy of militia; nor can troops be quartered in the province. Whatever relates to its defence during war, or the preservation of tranquillity in the time of peace, belongs to the inhabitants exclusively. The Biscayans being all noble, hold a distinguished rank in the rest of Spain; and, excepting to the grand judge of Biscay, who has his tribunal in Valladolid, they are accountable to none other beyond the confines of their lordship. This, of all their privileges, is that which is guarded with greatest jealousy. Their laws and privileges equally remove them from the conditions of most other subjects of the kingdom; for their affairs are determined by a general assembly of representatives, which is convoked every two years. These representatives meet under the tree of Guernica, a venerable oak, which has resisted the elements for centuries. Thither Ferdinand and Isabella repaired, after high mass, in 1476, and swore to preserve the privileges of the Biscayans entire. When the king raises an army, they are bound to march, at their own expense, to another tree, called Malato, on

their confines, but having passed it, they are entitled to receive pay.

The Biscayans preserve a decided difference of character from the other Spaniards. They are of a gay and lively disposition, friendly, and hospitable. They are faithful, active, and industrious; but as if to counterbalance these good qualities, they are reputed obstinate, irritable, and impatient. Here the women are equally active as the men: they participate in the most laborious employments, such as working in the fields, rowing boats, and carrying burdens on their heads, which require the strength of two men to lift up. "The wife yields not in strength to the husband, nor the sister to the brother;" and they share in sports elsewhere peculiar to men, such as tennis, in which they show themselves their successful rivals. The people in general are patient of fatigue: in good and bad weather, they travel to an incredible distance to attend their parish churches, many of which are very far asunder. The inhabitants of Guipuzcoa are fond of bull-fighting, with which the villagers celebrate the festivals of their tutelary saints, and thither the inhabitants of the neighbouring villages resort to enjoy the barbarous entertainment. The bulls of Spain are said to be more ferocious, and better adapted for being pitched against each other, than those brought from abroad; which Bowles ascribes solely to the influence of climate. Perhaps there is some foundation for his opinion; for it is undeniable, that all animated nature is deeply affected by the influence of climate, and much of the manners and customs of the whole human race may even be traced to its effects. It is well known, that animals of the same species are less ferocious in one region than another, and that under the same degrees of latitude incipient customs arise nearly at the same stage of civilization among nations. The universal privilege of nobility produces a principle of dignity among all the Biscayans from the highest to the lowest, and on proving that they originally belonged to the lordship, or come in lineal descent from those who did, they are entitled to claim public certificates of being gentlemen by blood. The three cantons have many ancient seats, consisting of strong plain edifices with square towers, which have existed from time immemorial. The owners of these are distinguished by the title of *Hidalgos de Casa Solar*, or gentlemen of known property, the most honourable appellation in Spain. The head of the family is called *Pariente Mayor*, and is greatly respected by all the collateral branches. The origin of such *Casas Solares* is thought to have been anterior to the establishment of Christianity in Spain, and before the use of archives or armorial bearings was known. But some of the owners are now so much reduced, as to be under the necessity of cultivating their estates with their own hands, while the branches which have come off their families flourish in opulence in remote provinces. Simplicity of manners is one striking characteristic of the Biscayans: the wives and daughters of the most wealthy do not disdain useful occupations in their domestic economy. Unlike the arrogance of many European states, a proverb is current here, which marks the liberality of the people, *la pobreza no es vileza*, poverty is no blemish. Extreme gaiety prevails throughout the lordship of Biscay; the inhabitants are passionately fond of dancing, and on holidays a vast concourse assembles to dance under the trees to the music of a rustic pipe and tabor. Children who die young, are preceded to

the grave by musicians; the body is crowned with roses, and the followers tumultuously proclaim their joy at the blessed transition. The same origin has been ascribed to the Biscayans and the Irish, which opinion Guillermo Bowles, who himself sprung of an Irish family, supposes is corroborated by the similarity of customs still practised among them. The men and women of Biscay are extremely fond of pilgrimages. Collecting in troops, they journey from great distances to the churches of their tutelary saints, singing and dancing by the way to the sound of the tabor. The Irish do the same at the festivals of their patrons. The *Guizones* of Biscay, or the *Boulam keighs* of Ireland, are similar, from the sudden and dangerous quarrels that arise and terminate without any remaining rancour, and without a deadly weapon being drawn. The people of both countries are extremely choleric; the least occurrence irritates them, and they cannot endure the most trifling slight. The *Chacoli* of Biscay, and the *Shebeen* of Ireland, render them equally frantic, and greatly to be dreaded. The poor people in Ireland, as in Biscay, eat from the same dish without forks, and using their fingers; and they dwell in the midst of smoke. The ancient brogues are the shoes of Biscay, "and the women here, as in Ireland, wrap a *sabanilla* or *kerchief* round the head, wear red petticoats, frequently go barefooted, carry weights on their heads, and labour along with the men. These, and other concurring circumstances, afford strong presumptions that the natives of the two countries have had one common origin."

The modern Biscayans consider themselves descended from the ancient Cantabri, who offered the most determined resistance to the Roman arms, and who were distinguished by the same energetic character which marks their posterity.

Cantaber ante omnes hyemisque, æstusque, famisque,
Invictus palmamque ex omni ferre labore

Nec vitam sine Marte pati: quippe omnis in armis
Lucis causa sita et damnatum vivere paci.

SILIUS ITALICUS.

The Cantabrians having sought the alliance of the Gallicians and Asturians, ventured to engage the Roman army on the plain of Vittoria, where they were totally defeated, and driven to their mountains.

Cantaber, Agrippæ, Claudi virtute Neronis
Armenius cecidit.

HORACE.

The Romans finding themselves unable to conquer the Cantabrians by force, endeavoured to subdue them by famine, and so completely environed their retreats, that they were reduced to the utmost extremities. Then, it is reported, that, to avoid the slavery destined for them by their invaders, most of these brave people committed suicide; and Augustus having entered Biscay, partitioned it among his soldiers. Nevertheless, hostilities were frequently renewed by the survivors, until at length the Romans, in the uncertainty of human affairs, were, in their turn, over-run by the irruptions of barbarous nations. Biscay was in the next place conquered by the Moors: though not without a resistance equally resolute as that which had been offered to the arms of the Romans. After a revolt in the tenth century, we find it governed by a chief called Suria or Zuria, who, tradition says, was descended from the royal blood of Scotland. He constituted the province

into an independent lordship, the sovereignty of which was enjoyed by his posterity, until subsequent revolutions followed, and at length ended in the lord of Biscay acknowledging the dominion of the king of Castile. In the fourteenth century, Peter the Cruel, king of Castile and Leon, killed the lord of Biscay, usurped his possessions, and united them to his own; and since that period the kings of Spain have assumed the title of Lord of Biscay, which is still retained. (c)

BISCUIT-MAKING. As the process of making biscuits for the navy is rather curious, we shall endeavour to lay before our readers a very short account of it. After the meal and water are combined into large lumps of dough, it is kneaded by means of a machine, which consists of a roller, about six inches in diameter, and seven feet long. One of its extremities is fixed into the wall, so as to have a certain degree of play, while a man rides, as it were, on its other end. The lump of dough is then placed below it, and the man puts the roller into action, till the dough is sufficiently kneaded. In this state it is given to a second workman, who slices it with a large knife, for the use of the bakers who attend the oven. The rest of the process is effected by four workmen, two of whom take their station, each at the end of a large table that holds the dough; the third stands at a small table near the oven; the fourth stands at the oven, and the fifth supplies the peel. The dough is then moulded into something like muffins by the person on the farther side of the larger table. He then throws them to the man at the other end of the table, who puts the proper stamp upon them, and throws them upon the small table, where the third workman separates the different pieces into two, and places them under the hand of the fourth baker, who throws the bread upon the peel. The fifth workman receives the biscuits on the peel, and arranges them in the oven. All these successive operations are performed with such activity and exactness, that seventy biscuits are thrown in during a single minute. It is evident, that the biscuit first thrown into the oven would be baked sooner than the others; but this effect is obviated by the workman who moulds the dough, and who proportionally diminishes the size of the biscuits; so that those which are last thrown in require less heat than the others. The biscuits thus made are placed in drying lofts above the oven, and are afterwards packed into bags, of one hundred weight each and removed to the warehouses. (j)

BISCUTELLA, a genus of plants of the class T tridynamia, and order Siliculosa. See **BOTANY**. (w)

BISERRULA, a genus of plants of the class Diadelphia, and order Decandria. See **BOTANY**. (w)

BISERTA, a maritime town of Africa, in the kingdom of Tunis, situated at the bottom of the ancient Sinus Hipponensis, a beautiful gulf about four leagues in breadth. This town, which is still about a mile in circuit, was formerly very large, and contained about 6000 houses. It lies on a canal, which joins a large lake with the gulf already mentioned, and is defended by several castles towards the sea, and two towers which guard the entrance to the harbour. There are here two spacious prisons for holding slaves, and a large magazine for articles of merchandise. The remains of a long pier are still visible; and were it not for the inactivity of the Turks, it might be easily repaired, so as to preserve the harbour from becoming altogether useless. The inhabitants, who are chiefly employed in fishing between the months of October and May, obtain a great variety of

fish from the lake. The millets are deemed the best in this part of Africa; and their roes, when dried, are made into *botargo*, which is exported as a dainty to the Levant. The surrounding country abounds with fruit of all kinds, with cotton, corn, pulse, oil, &c. Population about 5000. E. Long. 9° 48', N. Lat. 37° 10'. (H)

BISHOP, a prelate, holding a barony of the king, and exercising ecclesiastical jurisdiction over a certain district called his diocese.

The term bishop is derived from *ἐπίσκοπος*, through the medium of the Saxon "bischop," and denotes an inspector, guardian, or overseer. In the dead languages, however, the word now commonly translated bishop, was originally used with a civil or political meaning attached to it, as, when Plutarch says, *Πανίᾳ διείπευε καὶ παντὶ ἐπίσκοπος ἢ αὐτῷ Φεΐδιᾳ, omnia ipsi administrabat et curabat Philus*, or when Tully is called *episcopus oræ et Campaniæ*; but, after the introduction of Christianity, it came exclusively to denote an ecclesiastical ruler. It is of course in this last sense only, that the Greek or Latin word is synonymous with the English "bishop." From the interpretation given above, it is evident, that the inspector, guardian, or overseer, may be considered either in relation to one church or assembly of Christians, committed to his care, or to a number of churches. The former in the notion of the Presbyterians and Congregationalists of all descriptions: the latter that of the Episcopalians and Roman Catholics. And, as far as the meaning of the word is concerned, there appears to be no doubt, that either idea may be included under it.

It is not to be questioned, that, in the early ages of Christianity, mention is distinctly made of an ecclesiastical officer, bearing rule not over a single church only, but over many churches; which officer must therefore have been a diocesan or bishop. This is allowed by the keenest advocates for presbytery; but they deny that such an officer, residing in one place, or confining his labours to a particular district or diocese, existed in the church during the apostolical age, and regard the introduction of such an officer as a culpable deviation from the primitive model. Here the parties are exactly at issue. It belongs not to us to attach ourselves to either side, but rather suppressing our own opinion, to give, as impartial historians, a short view of the arguments by which the Presbyterians on the one hand, and the Episcopalians on the other, have defended their respective opinions: disclaiming that intolerable bigotry which would make a devotion to our own forms, or to those of the hierarchy, the exclusive condition of future happiness.

The great object of the Presbyterians is to establish an equality among the teachers of religion, under the sanction of apostolical example, and the condition of the primitive church. With this view, they remark, that, among the apostles themselves, whether considered as ordinary or extraordinary functionaries, the equality for which they contend may be recognised. To none of these eminent persons was there given any jurisdiction or inspection over the rest, corresponding to that of a modern bishop or archbishop; not even to Peter, for, though the church is in one place declared to be founded *on him*, yet the same church is elsewhere said to be built, "on the foundation of the apostles and prophets" generally, Jesus Christ himself being the chief cornerstone. Upon this footing of equality, likewise, it was that Paul, in a remarkable instance, so far from yielding to the authority of Peter, "withstood him to the face," because, in his judgment, he was to be blamed. Nay,

there is upon record a precept of Christ, addressed immediately to the apostles, in which he enjoins them to mutual submission and forbearance. "Whosoever will be chief among you," says he, "let him be your servant," Matt. xx. 29. The same observations apply to the evangelists, in the number of whom are included Philip, Timothy, and Titus, as well as Mark and Luke, and also to the seventy disciples; for in neither of these instances are there any traces of subordination to be discovered. In supporting their leading proposition, the Presbyterians farther maintain, that the terms *ἐπισκοπος*, and *πρεσβύτερος*, are used as synonymous, and convertible in almost every passage of the New Testament where they occur; or, in other words, that the same persons who are called *ἐπισκοποι*, are likewise called *πρεσβύτεροι*, the former expression being the name of office, and the latter the epithet of respect. In proof of this assertion, they adduce the well-known passage in the 20th chapter of the "Acts of the Apostles." In that chapter, we are informed, that Paul, having summoned the elders of the church at Ephesus, *τῶν πρεσβυτέρων τῆς ἐκκλησίας*, the presbyters of the church addressed them, that is, the elders or presbyters, in the following words: "Take heed, therefore, to yourselves, and to all the flock over which the Holy Ghost hath made you (the presbyters) *ἐπισκοπους*, bishops, or overseers." Here (says Dr Campbell) "there can be no question, that the same persons are denominated presbyters and bishops." Nor does this passage by any means stand alone. There is a similar one in the Epistle to Titus, chap. i. ver. 5. compared with verses 6th and 7th. The reader may likewise consult 1 Pet. v. and 2.; but, for our remarks on these passages, as applicable to the present question, as well as for additional observations on the terms *πρεσβύτερος* and *ἐπισκοπος*, we refer to the article PRESBYTERY. We may conclude this paragraph, however, with stating, that, wherever the ordinary ecclesiastical functionaries are mentioned by the inspired writers, it is uniformly under the character either of presbyters (*i. e.* bishops or overseers,) or of deacons. Two classes of functionaries only are spoken of, without the most distant allusion to a third order, that of diocesans; yet, (say the Presbyterians) if this last order had existed, being, according to the Episcopalians, the most important of the whole, it would undoubtedly have been specified and noticed as that importance required. See *the Epistle to the Philippi*, chap. i. v. 1. See also the *First Epistle to Timothy*, chap. iii.

The advocates for presbytery next contend, that the bishops or presbyters of the apostolical age, were usually the pastors, each of a single congregation. They say, *usually* the pastors, each of a single congregation, because, as they affirm, there are instances where two or more pastors have been allotted to one Christian assembly; though the converse of this proposition is not true, that there are instances in the age referred to, of two or more congregations subjected to the authority of one bishop. In establishing the proposition enunciated above, it is asserted, that, when Titus, acting in the capacity of an extraordinary minister, was left at Crete, it was, for the following purposes, among others, "that he should ordain presbyters or bishops in every city," Tit. i. 5. Now, from this statement, it is evident, at first sight, that these presbyters or bishops could not be diocesans. Had it been the intention of Paul to establish, by the agency of Titus, a diocesan authority in Crete, we should have found one individual put in possession of

that authority, with a college of priests for his assistants. But this was not the case: Titus was left to ordain presbyters or bishops in every city, that is, to furnish the Christians of each city with an ordinary pastor. From the most ancient catalogues and histories, with which we are acquainted, we learn, that there were eleven of these pastors in the island alluded to; a fact obviously incompatible with the Episcopalian hypothesis, unless we can believe, that, in the small island of Crete, and at this early period of the church, there were no fewer than eleven diocesans, each having an array of priests and congregations under his ecclesiastical jurisdiction. The presbyters or bishops, ordained by Paul and Barnabas, (Acts of the Apostles, xiv. 23.) appear likewise to have been the spiritual instructors of individual churches. In short, say the advocates for presbytery, the fact is, as we have stated it, and, taking the inspired writers as the highest and best authority, our antagonists will search in vain for the office of a bishop, according to the modern interpretation of that word, among the functionaries established by the apostles in the Christian churches. This is even allowed by many of the Episcopalians themselves, "*Est sane admodum precaria,*" says Mr Dodwell, "*omnis illa argumentatio qua colligitur disciplina ecclesiastica in posterum recipienda, rationem omnem e Scripturis Novi Faderis esse hauriendam. Nullus enim est qui id proficiatur aperte sacri scriptoris locus.*" *Parænesis*, N. 14. Can that, therefore, (the Presbyterians ask,) be an institution of Christ, for which there is no authority in the sacred writings, and which, by the account of the author just quoted, was not in existence before the conclusion of the apostolical period?

We should here introduce a conspectus of the arguments for a government by church-courts, composed of members all possessed of equal authority, together with the criticisms on the word *πρεσβυτηριον*, as it occurs in sacred scripture; but the limits prescribed for this article, oblige us to refer the reader to another part of our work. See PRESBYTERY.

To the arguments of the Presbyterians, the friends of Episcopacy have not been backward to reply. They contend, that both the name and authority of bishops may be referred to a very early period of the Christian church. They regard the apostles themselves as a college of bishops; and their successors, in the episcopate, as deriving from them their jurisdiction and privileges. They give more weight than the Presbyterians allow, to a tradition, which, they say, prevailed universally in the times immediately succeeding the apostolical period, and from which they consider themselves as entitled to affirm, that James, the son of Alphaeus, otherwise called James the Less, and the Lord's brother, was the first bishop of Jerusalem; and, by the same authority, that Peter was the first bishop of Rome. In corroborating this tradition, they quote a passage from Tertullian, an author who lived in the second century, where he challenges the heretics "to exhibit the order of their bishops, so succeeding each other from the beginning, that the first bishop had *for his author and predecessor* some one of the apostles, or of those apostolical men who were their companions in labour;" a challenge which evidently supposes, that the orthodox Christians were able to exhibit such an order: And, accordingly, he goes on to state, that "the church of Smyrna has Polycarp placed there by St John; that the church of Rome has Clement ordained by St Peter; and that the rest of the churches show other persons, who, being placed in the bishoprics

by the apostles, transmitted the apostolical seed." (*De Præs. adv. Hæretic.* p. 78.) The examples of Timothy and Titus, however, appear to be more decisive in favour of Episcopacy than that of the apostles. Hence much authority has been ascribed to these examples, considered as a part of the original institute, more especially intended for the direction of succeeding ages. At the same time, it must be granted, that no little doubt has been entertained with respect to the exact nature of the office held by these evangelists. But, while this is granted, it is (say the Episcopalians) not to be denied, that many things concerning them are abundantly certain. The introduction of Episcopacy seems to have been progressive. Though it be admitted, that there were presbyters or elders of the church, at Ephesus (Acts xx. 17. and 28.) in the year 58, and that these presbyters or elders, are, in a general sense, denominated bishops, as exercising functions similar to those of the episcopate; and though it be farther admitted, that when these presbyters or elders are spoken of, it is without any allusion to an individual bishop at that time existing among them, yet it must be considered, that this was the early and imperfect state of the Ephesian church. For we are told, that, in the year 64, when Christianity was more advanced, Timothy was established at Ephesus by Paul, to ordain elders, and stop the progress of divisions and schisms; or, in other words, he was settled there with authority, corresponding to that which we now call Episcopal, (1 Tim. i. 3. and iii. 1.) Accordingly, the apostle wrote, in the same year a letter to Timothy, in which he laid before him the necessary duty of a bishop, as well as the requisite qualifications for that office. The patrons of Episcopacy likewise inquire, "what is it, after all, that constitutes the chief difference between our antagonists and us?" And they answer the question: The chief difference consists in this, that, with us, the right or power of ordination resides in an individual, while, with them, it belongs to a court. Now we contend (say they,) that the former of these is established, and the latter excluded by the instance or case of Titus. He was left in Crete for this especial purpose, that he, not a court, but an individual, might ordain presbyters or elders in every city. And, from the example of Titus, or rather of ordination by an individual, exemplified in him, they denounce the Presbyterians, sometimes perhaps with more fury than the argument drawn from the case will allow, as unlicensed and daring intruders into the ministry of the New Testament.

Another argument employed by the Episcopalians is taken from the Epistles to the seven Asiatic churches, mentioned in the Apocalypse. The epistles alluded to are not addressed either to the churches in general, or to any assembly of the rulers in these churches, but to an individual, called in each instance "the angel of the church," (Rev. ii. 1.) "To the angel of the Church of Ephesus, write these things:" "To the angel of the Church of Smyrna, say;"—and so in all the other cases. Now, the Episcopalians maintain, that the individuals here denominated the Angels of the Churches, were the bishops of these churches. The language, they say, is taken from that in common use among the Jews when speaking of the synagogue; a circumstance which, in their opinion, gives additional strength to the argument: For if the angel of the synagogue was the individual who presided over the synagogue, it follows, by analogy, that the angel of the church was the individual who presided over the church, that is, the bishop. It is

allowed, however, by some of the Episcopalian writers, that the argument derived from the mode in which the Asiatic churches are addressed, is corroborative merely: They admit, that by the angel of the church may be understood, either the pastor of that church, or the bishop under whose government it was; but they contend, that Episcopacy being established on other considerations, the mode of addressing the Asiatic churches gives to these considerations a weight or force which renders them altogether irresistible.

In addition to the arguments already mentioned, the patrons of the hierarchy assert, that the authority of the early fathers is wholly on their side; an authority the more to be valued, because, from the times in which they lived, they must have had the best opportunity of knowing the true characters of the primitive institution. At the head of the fathers, to whom they allude, stands Ignatius. According to Chrysostom, he was the frequent and familiar associate of the apostles, and received episcopal ordination from them by the imposition of hands. In an epistle to the Magnesians, ascribed to this eminent person, he distinctly refers to three orders of functionaries existing in the same church: mentioning Damas as bishop of Magnesia, Bassus and Apollonius as presbyters, and Totian as deacon. In his Epistle to the Philadelphians, a similar enumeration is given: "Attend," says he, "to the bishop, to the presbytery, and to the deacons." A passage from his Epistle to the Trallians is yet more emphatic and conclusive: "Be ye subject," he says, "to the bishop as to Jesus Christ, to the presbyters as the apostles of Jesus Christ, and to the deacons as ministers of the mysteries of Jesus Christ;" and he adds, with an anxiety and earnestness not to be expected in so early a writer upon such a subject, these remarkable words, "*without these there is no elect church, or congregation of holy men.*" To the same purpose the authority of Clement, bishop of Alexandria, who also lived in the second century, is adduced: He, too, speaks of the three orders of functionaries existing in the church, and mentions several persons who had arrived at the episcopal dignity, through the intermediate gradations of presbyter and deacon. To the testimonies of Ignatius and Clement, the Episcopalians add those of Tertullian, of Origen, and Jerome, and boldly and clamorously affirm, that the voice of all antiquity is in favour of the model for which they contend.

Such is a short, and, we trust, an impartial account of the arguments by which the Presbyterians and Episcopalians endeavour to support their respective tenets; and so much have the authors on both sides been persuaded that their opinions are well founded, that they have maintained, on the one hand, the *divine right* of Presbytery, and, on the other, the divine right of Episcopacy. There are, however, at present, in this kingdom, men of education and judgment, who think, that both parties have proceeded too far, and claimed too much. They see, that there is no form of ecclesiastical polity established, by specific precept, in the inspired writings, and are willing to admit, that even the practice of the apostles in this respect was not the consequence either of distinct information received from the Author of our religion, or of immediate inspiration from above; but that it was, as in the choice of the deacons, the result of the circumstances in which they were placed. According to these persons, any form of ecclesiastical government, which shall secure the intelligence and diligence of the clergy, and the regular instruction of the people, may be conscientiously adopted.

Nor is this opinion at all peculiar to the time in which we live. It appears to have been that of the celebrated Mr Locke. "A church," says this distinguished philosopher, "I take to be a society of men, joining themselves together of their own accord, in order to the public worship of God, in such a manner as they judge acceptable to him, and effectual to the salvation of their souls." (*Letter on Toleration*, p. 40.) And having stated the objection, that no society can be regarded as a true church unless it shall have in it a presbyter, or bishop, deriving his authority from the apostles, he continues, "To those who make this objection, I answer, let them shew me the edict by which Christ has imposed that law on his church: And let not any man think me impertinent, if, in a thing of this consequence, I require that the terms of that edict be very express and positive; for the promise he has made us, *that wherever two or three are gathered together in his name, he will be in the midst of them*, seems to imply the contrary." (*Ibid.* p. 44, 45.) In conformity with these sentiments, many learned doctors of the English church have admitted, that Episcopacy was to be supported, not so much as a divine institution, or established by apostolical authority, but because it was the mode of church-government best adapted to the people of England, and acknowledged by the custom and ordinances of that kingdom. This is said to have been the opinion of Cranmer and others among the reformers, as well as that of Brydges, Whitgift, and even of Hooker himself. Archbishop Usher and Burnet are likewise said to have maintained this opinion. See Stillingsfleet's *Irenicon*, c. 8.; Burnet's *Hist. of Reform.* i. Ap. p. 321.; and *Vindic. of the Church of Scot.* p. 336.

The right of electing bishops is vested, if not by law, at least by the practice of the English church, in the king. Immediately after the demise of any prelate, notice of that circumstance is given to the crown by the dean and chapter of his cathedral; who, at the same time, request permission to supply, by their choice, the vacancy which has taken place. His majesty then issues what is called a *congè d'elire*, accompanied by a missive, or recommendation of some individual to the benefice. This recommendation has the full effect of a command; for the dean and chapter have not the privilege of rejection. Should they decline electing, and persist in declining for the space of twelve days, they incur the severe penalties of a *præmunire*, under which term are implied, outlawry, or exclusion from the king's protection; a forfeiture to the crown of lands and tenements, goods and chattels; and imprisonment during his majesty's pleasure. After the interval of twelve days just alluded to, the king presents, by his letters patent to the vacant see. The election, or presentation, is next intimated to the archbishop of the province, who is required to proceed without delay in confirming the bishop elect. Should he decline, he likewise incurs a *præmunire*. The mandate, requiring confirmation, bears the authority of the great seal. As soon as it is received by the archbishop, it is transmitted to an officer called his vicar-general. The ceremony of confirmation then takes place. Those, who have any objections to the new bishop, are solemnly invited to appear and substantiate them, and are denounced, as contumacious, if they refuse to do so. The oaths of allegiance and supremacy, together with that of canonical obedience, and that against simony, are next administered. A minute of the proceedings is then read by the vicar-general,

after which the bishop is installed or constituted the ecclesiastical superior of his diocese, being fully invested with episcopal authority; though, according to some lawyers, he cannot lay claim to the temporalities of his benefice, unless he shall have been consecrated by the archbishop. The ceremony of consecration differs in some respects from that of confirmation. It must be performed, as we have just intimated, by the archbishop; or, in particular cases, by three bishops, lawfully commissioned for that purpose. The essential parts of this ceremony, according to Burnet, (xxxix. *Art.* p. 564.) are prayer and the imposition of hands; but to these are added, investiture with the episcopal robes, together with the use of a certain form of words adapted to the occasion.

By the law and ordinances of England, all bishops, with the exception of one, the bishop of Sodor and Man, are lords of Parliament, though not peers of the realm. In the reign of William the Conqueror, the spiritual tenure of *franc almoign* was converted into the feudal tenure by barony; and the bishops, now constituted barons, became of course members of the great council, or parliament, of the nation. In consequence of this change, when, upon one occasion, the bishops declined sitting and voting in the House of Lords, the king availed himself of his right implied in the feudal tenure, and commanded their attendance. The ecclesiastical barons are likewise members of the Upper House by writ or summons of the crown; a circumstance which, according to lord Coke, is equivalent in this respect to a barony. But, exclusive of that circumstance, and exclusive, too, of the right connected with their baronies, the spiritual lords hold their seats by patent or creation; so that they are lords of Parliament in three ways, as barons, by writ, and by patent. Hence all the deeds of the Upper House run in the name of "The lords spiritual and temporal," and hence the bishops have the precedence of all barons whatever. Sir William Blackstone is of opinion, that, in the absence of the temporal peers, a vote of the bishops alone would be considered as a vote of the House; though it was decided by the judges (7th Hen. VIII.) that the king might hold a parliament without any spiritual lords. But the bishops, while they are acknowledged as lords of Parliament, are not regarded as peers of the realm. (Stamford, *P. C.* 153.) They do not sit in the court of the Lord High Steward; and though they may *stay and sit* in cases of trial for capital offences before a full parliament, yet they must retire before the vote of guilty or not guilty takes place. The exclusion of the bishops in both of these instances arose from this, that, by the canons of the church, they could not be judges in matters of life and death. For some such reason, too, or from the want of nobility in blood, a bishop cannot be tried in the court of the high steward. As ecclesiastical functionaries, the prelates have the rights of dedication, confirmation, and ordination, as well as those of suspension, deposition, deprivation, and excommunication; they collate to benefices, and direct institution and induction in cases of presentation by other patrons; they take care of the probate of wills, and grant administrations; and they certify to the judges in affairs of lawful and unlawful marriages and births. In England there are twenty-four bishops, exclusive of the bishop of Sodor and Man. Among themselves, the bishops of London, Durham, and Winchester, have the precedency of the others in the order in which we have mentioned them. The rest follow, with some officia

exceptions, according to the date of their consecration. A bishop has the style of *My Lord*, and is addressed *Right Reverend Father in God*. See Stillingfleet's *Works*, vol. i. p. 371. and vol. ii. p. 396. King's *Constitut. of the Primat. Church*, ch. i. &c. Prettyman's *Elem. of Chr. Theol.* vol. ii. p. 376, *et seq.* Campbell's *Ecclesiast. Hist.* vol. i. p. 84, *et seq.* Musheim, vol. i. p. 104, *et seq.* Brown *On Church Government*, p. 281, *et seq.* *Altare Damascenum, passim.* (h)

BISHOP AUCKLAND. See AUCKLAND.

BISHOPS STORTFORD, a market town of England, in Hertfordshire, situated on a rising ground upon the river Stort, in the midst of a fertile corn country. The town consists of four principal streets, intersecting each other at right angles, in the direction of the four cardinal points. The church, dedicated to St Michael, is a handsome Gothic building, situated on an eminence. The free school is an elegant square building opposite the church, and stands upon arches, beneath which is a place for shops. On an artificial mound between this town and the village of Hockerel, are the remains of an ancient castle, built in the time of William the Conqueror, though others suppose that it was erected previous to the Norman invasion. A considerable trade is carried on in brown malt, which is sold to the brewers in London, to which it is conveyed by a navigable canal which joins the river Lea. Number of houses 421. Population in 1801, 2304, of which 453 were returned as employed in trade and manufactures. See Salmon's *History of Hertfordshire.* (π)

BISMUTH. See CHEMISTRY and ORYCTOGNOSY.

BISNAGUR, or BIJNAGUR, and sometimes written BEEJANUGGUR, is situated on the southern bank of the Toombuddra river, in the country of Mysore, and was formerly the capital of a powerful kingdom of the same name in Hindostan, which extended from Cape Comorin to the frontiers of Orissa. According to the Portuguese writers, it was built by prince Boka, about the year 1200, and was then called Visianagur; but Ferish-ta relates, that it was founded by Belaldeo, king of the Carnatic, in 1344, in order to guard the northern frontier of his empire. In 1565, it was a very large city, about twenty-four miles in circuit, and containing within its walls a number of hills and pagodas. Its ruins are very extensive, nearly eight miles in circumference, and many of its temples are still remarkably beautiful. Several streets, from 30 to 45 yards wide, have been traced among its rugged hills and rocks; and one particularly, about 35 yards in breadth, and extending half a mile in length, with colonnades of stone on each side, and a very large pagoda at one end, is said to be in a state of complete repair. The soil in its neighbourhood is fruitful, and well watered, abounding in cattle and deer. Its inhabitants are well shaped, and very ingenious in watering and painting calicoes, which is the chief trade of the place. It lies directly opposite to Anna-goondy, is about half a mile distant from Fort Comla-pour, 140 geographical miles or eight days journey from Goa, 172 miles north of Seringapatam, and 132 south of Visiapour. Its N. Lat. is 15° 15', and its E. Long. 76° 34'. (q)

BISSAGOS. See BIJUGA.

BISSAO, is an island on the western coast of Africa, north of the Bijuga channel, the centre of which lies in about 11° 30' N. Lat. and 15° W. Long. Some geographers, as we have already observed, incline to class it with the Bijuga islands; but, in our opinion, it would,

along with the neighbouring ones on the same side of the channel, more properly form a separate groupe.

Bissao is above 40 miles in length, and is said to be from 35 to 40 leagues in circumference: it gradually rises from the shore to the centre, where there are hills discharging springs, which fertilize the country. The soil is rich, and productive of fruits, grain, and other vegetables; orange trees grow to an extraordinary size; and the land is cultivated to great advantage.

The natives of this island are a race of people called Papels, who in appearance are rather good looking, and in character are reputed industrious and faithful to those whom they serve. Their dress is a piece of cotton put round the loins, hanging down to the knees, but boys and girls go naked. All are idolaters, and offer sacrifices of cocks, dogs, and oxen, which are carefully fattened, and, when cut in pieces at the sacrifice, are eaten by the king, his attendants, and those who are present. They suppose their divinities reside in consecrated trees, on which they hang the horns of the oxen as an offering. The principal idol of the natives is called *Chine*, but they have very indistinct ideas of its powers or properties. They entertain strange and extravagant superstitions concerning witchcraft, firmly believing that one may be bewitched by another, who gradually devours him by sucking his blood. Of this captain Beaver relates a remarkable instance within his own knowledge: and here we can trace a faint analogy to the credulous times of antiquity in Britain, when it was credited that the wasting of an image was fatal to the life of the original. Some of the free natives employed by that officer accused two of their own number, asserting, that one of them could transform himself into an alligator, and devour people; and that the other was said not to be a good man, because he wished to eat his companion; that he had long been reputed a wizard; and that his mess-mates, in the voyage from Bissao to Bulama, could hardly be restrained from throwing him overboard. Many people, the accusers affirmed, had been destroyed by his infernal art, which was the reason he had left his own country; and if ever he returned he would be sold for a slave: They therefore requested permission to punish the two culprits after their own fashion, by tying them to a tree, and flogging them, promising at the same time that their lives should be safe. Captain Beaver, willing to save the men, endeavoured to dispel the apprehensions of their companions; and to give him, who was accused of transforming himself to an alligator, an opportunity of self-vindication, inquired whether the assertions were true. "Yes," replied the man, "I can change myself to an alligator, and have often done it." The singular coincidence between the belief of these people and the superstitions of old in this kingdom, when confessions were made of witchcraft, cannot escape observation.

The island of Bissao is ruled by thirteen chiefs, who are generally at war among themselves; however, some French authors affirm, that there is only one king, who has eight subordinate chiefs, each governing a province. The natives carry on frequent wars in their canoes which contain 20 or 30 men, though they commonly last only a few days. The warriors, on their return, are received with great rejoicings; and the prisoners whom they have taken are sold for slaves, and produce much emolument.

About two centuries ago, the Portuguese established a settlement on Bissao, which still subsists; but the

French claim the discovery of the island, maintaining, that some Normans anciently fixed themselves there, and afterwards withdrew, owing to the decline of their trade. The profits of the Portuguese, and the product of traffic from the island, being 400 negroes yearly, 500 quintals of wax, and 300 or 400 of ivory, induced them to return. It is probable that they intended to expel the Portuguese by force, as the governor-general of Senegal provided a body of troops, and in March 1700 appeared before the settlement with seven ships of war. The Portuguese not being in a state to make opposition, the French, with the permission of the native chiefs, established a factory, and, by their enterprize and activity, soon engrossed the whole trade. In consequence of this change of circumstances, the Portuguese demolished their buildings, and abandoned the island. Their absence, however, does not appear to have been long: They returned, and constructed a large regular square fort, with four bastions, on which are now mounted nearly 50 guns, and it contains a garrison of about 300 or 400 soldiers. The traffic increased, and they sent no less than 2000 slaves yearly to Brazil, besides carrying on a trade with Europe. Most of these slaves were purchased from the Mandingoes at Geba, some from the Cacheo and Casamanza rivers, a number from the Nalooos, and a few from the Bijuga and Biafara nations. The slaves now purchased by the merchants of Bissao, are procured by means of a class of the natives called Grumetas, who have usually been reared from infancy in their houses, and, for the most part, are a sober, industrious, and faithful class of people. While the merchant seldom quits his own habitation, they navigate all the small craft, or are sent to the interior of the neighbouring continent with goods, the return for which they faithfully bring home. But, of late years, the trade of the Portuguese in that quarter has greatly declined, though vessels from different parts of the world employed in the slave trade occasionally reach Bissao. The French at present have no settlement there, nor do we know when they left the island for the second time: Some years ago, we believe, it was in contemplation to return, as they supposed that 1500 slaves, and likewise a great quantity of ivory, wax, and rice, might be annually obtained. See Delajaille *Voyage au Senegal*. Durand's *Voyage to Senegal*. Beaver's *African Memoranda*. (c)

BISSENPUR, a small district in Bengal, under the government of a Bramin family of the tribe of Rajpoots. It is entirely surrounded with water; and, by opening the sluices of the rivers, the whole country can in a short time be completely inundated. By the singularity of its situation, its inhabitants have uniformly maintained their independence, making only a show of submission, and paying occasionally a voluntary tribute to the Moguls. In this district, the laws and character of the Hindoos are said to be found in their most unadulterated state; and the golden age, if the accounts of historians are to be credited, still exists among this favoured people, in all its purity and simplicity. Here, we are told, though we are not hasty to believe, that the stranger is completely secure under the protection of the laws; that he is provided with guides, who are responsible for the safety of his person and property; and that, if he remains no more than three days in the same place, he is maintained and forwarded at the expense of the state; that robbery is unknown; and that so prevalent is the spirit of probity, that, should any one

find a purse, or any other article of value, he hangs it upon the next tree which he meets, and informs the nearest guard of the circumstance, who immediately gives notice to the public by beat of drum. See Raynal's *History of the East and West Indies*, vol. i. p. 415 (g)

BISSEXTILE, or LEAP YEAR. See **CHRONOLOGY**.

BITHYNIA was an ancient kingdom of Asia Minor, bounded on the north by the Euxine Sea, on the east by the river Parthenius, on the south by mount Olympus and the river Rhyndacus, and on the west by the Propontis and the Thracian Bosphorus. The information which we derive from the page of ancient history respecting this country, is so full of contradictions, that it appears impossible to ascertain what leader laid the foundations of this dynasty, or what people obeyed his command. But as we meet with the Cimmerii, the Mariandyni, the Bebryces, the Caucones, the Doliones, roaming through this region at an early period, it is probable that it was first inhabited by various independent tribes. But, instead of conducting Nimus to the conquest of this country, by the doubtful light of Diodorus; instead of repeating the tale of Appian, concerning the 49 kings who reigned there before the Romans visited Asia; instead of marching with the Thracians, from the ruins of Troy, to take possession of this region,—we shall confine ourselves to that period of its history which, being better authenticated, claims more deservedly our attention.

From the doubtful light which first rises on the history of this country, we imagine, that Prusias governed in the time of Cræsus, and that he was subjugated by the Lydian prince. But the conquerors and the conquered were doomed to yield to the Persians, under Cyrus the Great; and under their yoke Bithynia groaned till Alexander broke the power of Persia, and annexed it to his vast empire. Bas, the son of Boteras, governed about this time the dependent kingdom of Bithynia; but, disdainful the name without the dignity of royalty, he inspired his subjects with his own independent spirit, defeated Calentus, whom Alexander sent against him, and maintained his freedom during a long reign of 50 years. Zipoetes, who succeeded him, waged an unsuccessful war with the brave inhabitants of Heraclea; but would have reduced to subjection the Chalcedonians, whom he next invaded, if he had not been forced to abandon the siege of their capital, to oppose the army of Antiochus Soter, king of Syria, which, commanded by Patrocles, suddenly burst into Bithynia. He did not long survive a complete victory, which by valour and stratagem he gained over the Syrians, but, in the 48th year of his reign, left the kingdom to his son Nicomedes. This prince disgraced his throne by the inhuman murder of two of his brothers. Zipoetes, the youngest, fled to Asiatic Thrace, and engaged the inhabitants to assert his cause. Nicomedes, when ready to reduce that revolted province, was informed that Antiochus was preparing to fall upon him. Distrusting his own power, he invited, from the western shores of the Bosphorus, the Gauls into Asia, and promised them a settlement in that country. Assisted by these barbarians, he defeated Antiochus, expelled his brother, and, either from a principle of justice or fear, yielded the territory which his brother possessed to the Gauls, which from them was denominated Galatia. Nicomedes employed the remainder of his reign in building a magnificent city, to be the capital of his kingdom, and which, from his own name, he called Nicomedia.

Tibites, his youngest son, to whom, at the instigation of that prince's mother, he had bequeathed the kingdom, succeeded him; but Zela, his eldest son by a former marriage, left Armenia, whither he had been banished by the intrigues of his stepmother, procured the assistance of the Galatians, expelled his brother, and ascended the throne. But Zela perceived, that the band which he had employed against his brother might soon be employed against himself, and began to suspect the fidelity of those whose power he dreaded. Wanting courage to subdue their arms, he had recourse to treachery, and, inviting the nobles of Galatia to a splendid entertainment, he prepared a band of ruffians to assassinate his guests; but the Galatians received private intelligence of his design, and murdered him at the beginning of the entertainment.

Though his son Prusias II. was successful in the wars which he waged against the Byzantines and the Galatians, yet he acquired a more distinguished renown when he invaded Pergamus, assisted by the wisdom and valour of Hannibal. That consummate general, forced by the ingratitude of his country to seek an asylum in a foreign land, arrived at last at the Bithynian court; and such was the influence, which his transcendent genius acquired over the mind of Prusias, that at his solicitation, he renounced the friendship of the Romans, and declared war against Eumenes, who was under their protection. But Eumenes depending upon the aid of the Romans, though still more upon the energy of his own mind, defeated his forces both by sea and land, and reduced him to such distress that he was ready to accept of peace. But the restless mind of Hannibal, ever fruitful in resources, informed that Philip king of Macedon was enraged against Rome and Pergamus, endeavoured to wield the resentment of that monarch to accomplish his own revenge, and persuaded him to join his army to that of Prusias. Prusias renewed the war, and employing various stratagems invented by Hannibal, saw his arms crowned with the most brilliant success. But the Romans, trembling for the fate of Eumenes, sent ambassadors to mediate a peace between the contending princes, and to induce Prusias to deliver Hannibal into their hands. The glory which Prusias had gained on the field of battle, was tarnished by his ingratitude to that illustrious hero, whom, as the price of Roman friendship, he abandoned to his implacable enemies. Indignant at the treachery of Prusias, Hannibal deserted a court that was unworthy of his presence, and retiring to Libyssa, put an end to his life.

Prusias now became the slave of the Romans, joined them against the Macedonians, and went to Italy to congratulate them upon this success. But before he entered Rome, he laid aside the ensigns of royalty; and, in the dress appropriated to slaves when they receive their freedom, was introduced into the senate. His meanness and servility sealed the degradation of his own mind, but could not be grateful to that venerable assembly, nor reflect glory upon the majesty of the Roman name. He returned home; but the historic muse would blush to describe his conduct afterwards, in which, without the semblance of one virtue, was exhibited every vice which could entail misery upon his subjects, or infamy upon himself. But the memory of his past achievements made him still formidable to his neighbours; and when he heard that Attalus had succeeded his brother Eumenes, he again invaded Pergamus, entered the capital of that kingdom, and exercised the most unrelenting cruel-

ty during the space of three years. At the end of that period ambassadors from Rome arrived to reconcile the hostile princes, and a conference was agreed to, upon the confines of the two kingdoms. But Prusias, following his dark policy, endeavoured with his army to cut off Attalus and the ambassadors, who were repairing to the place appointed, but his design was discovered, and they escaped by flight. The senate threatened vengeance, but Prusias would have despised threatenings, if he had not been informed that Athenæus, the brother of Attalus, with a powerful fleet, was spreading devastation along the Bithynian coast, and that Attalus himself had raised another formidable army. Peace therefore was at last obtained, and Prusias sent his son Nicomedes to Rome, either to complete his education, or to procure from the senate a remission of some disagreeable articles of the treaty. But Nicomedes no sooner gained the friendship of the Romans, than the suspicious mind of Prusias became jealous of his designs. Prusias immediately sent Menas, one of his favourites, to Rome, as his ambassador, but with the private design of cutting off Nicomedes. Whether fear or remorse animated the mind of Menas, we are uncertain, but he revealed the unnatural design to the son; and the danger to which, from that moment, both were exposed, incited them to secure themselves by the death of Prusias. Nicomedes so sensible of Pergamus, procured the assistance of Attalus, invaded the territories of his father, and was every where received as the deliverer of his country. Not daring to trust the few Bithynians who still remained with him, Prusias fled from city to city, in the fond expectation that ambassadors would arrive from Rome to adjust the differences between him and his son. Ambassadors did arrive, but they were men who could form no decisive measures, nor give them efficacy if formed, and proved that the Romans could sport with the feelings of a prince, who had taught them to despise him. Nicomedes and Attalus advanced to Nicomedia, where Prusias had shut himself up; the gates were immediately thrown open by the revolting inhabitants; and in the temple of Jupiter, whose sanctity could afford him no protection, the father fell by the hand of his son.

Nicomedes II. ascended the throne, but not to realise the hopes of his country. Though he assumed the name of *Epiphanes*, or the *Illustrious*, yet the only action which he performed, during a reign of 42 years, to vindicate his claim to that lofty appellation, was the murder of his brothers. He died a violent death; but that it was inflicted by his son appears to be a conjecture originating in that love of retributive justice which is natural to man. His son, Nicomedes III. overran Paphlagonia, invaded Cappadocia, expelled Ariarathes, and, to secure the kingdom to himself, married the mother of that prince. But Ariarathes procured the assistance of Mithridates the Great, who not only drove Nicomedes from that kingdom, but expelled him from his own dominions. Being restored by the Romans, in an ill-fated hour, he invaded the kingdom of Mithridates, and that high-spirited prince met him on the banks of the Amnion, dissipated his forces with dreadful slaughter, and again forced him into exile. The Romans again seated him on the throne, but dying soon after, he left his dominions to his son Nicomedes IV., whose name can only claim a place in the page of history as the last of the Bithynian kings. As he had no son, he left his kingdom to the Romans. A daughter, named Musa, survived him, who afterwards claimed the kingdom for her

son. But the Romans rejected her claim, and retained it as a province, till it was wrested from them by the Turks, to whom it still belongs. (N)

BITS. See BRIDLE.

BLACK, DR JOSEPH, was born in France, on the banks of the Garonne, in the year 1728. His father, Mr John Black, was a native of Belfast in Ireland, but of a Scots family, which had been for some time settled in that country. Mr Black resided for the most part at Bordeaux, where he carried on the wine trade. He married a daughter of Mr Robert Gordon, of the family of Hillhead in Aberdeenshire, who was also engaged in the same trade at Bordeaux. In the year 1740, when young Black had reached the age of 12, he was sent home to Belfast, that he might have the education of a British subject. After the ordinary instruction of a grammar school, he was sent in 1746 to continue his education in the university of Glasgow. Being required by his father to make choice of a profession, he pitched upon medicine, as most suited to his peculiar views, and congenial to his studies.

Fortunately at this period Dr Cullen began his great career, and had pitched upon philosophical chemistry as a field hitherto untraversed and unopened. It had been treated as a curious art, susceptible of improvement from rational inquiry and discussion. But Dr Cullen saw in it a great department of the science of nature, founded on principles as immutable as those of mechanical philosophy. He undertook the task of developing and arranging these principles, and he promised to himself great reputation from the accomplishment of it. His pupils, in consequence of his new views, became zealous chemists, and young Black in particular devoted himself to the study. This was soon observed by Dr Cullen, who possessed the happy talent of exciting and encouraging his pupils in an eminent degree. Mr Black became his intimate friend, his assistant in all his investigations, and his experiments were frequently quoted in the lecture as sufficient proofs of the positions of the professor.

In 1750 he went to Edinburgh to finish his medical studies, and he lived in the house of Mr James Russel, professor of natural philosophy, his cousin-german. About this time the professors had adopted different opinions respecting the action of lithontriptic medicines. Those which produced the most powerful effects in alleviating the excruciating pains of the stone, were of a very corrosive nature. It was therefore an object of great importance, to discover, if possible, some equally efficacious medicine, which shall not possess corrosive properties; or if that cannot be done, at least to diminish or destroy the corrosiveness of the medicines in use, without impairing their medical virtues. It was these views that led Mr Black to investigate the nature and properties of magnesia, and which induced him to contrive and execute the experiments which laid open the nature of causticity itself, and showed upon what it depends. This important subject he destined for his inaugural dissertation; and he appears to have delayed taking out his medical degree till he had brought his investigation to a state of maturity.

Fortunately when he took his doctor's degree, and published his important discovery of the cause of the difference between limestone and quicklime, mild and caustic alkalies, a vacancy occurred in the chemical chair in Glasgow. His friend and master Dr Cullen having been removed to Edinburgh, there could be no

hesitation in bestowing the vacant chemical chair upon the author of a discovery, which was destined to produce a complete revolution in chemical science. Dr Black was accordingly appointed professor of anatomy and lecturer on chemistry in the university of Glasgow in the year 1756. Not considering himself as well qualified for the professorship of anatomy, he exchanged tasks with the professor of medicine, with the concurrence of the university.

While in Glasgow, therefore, his lectures on the institutes of medicine constituted his chief task. They gave general satisfaction, by their clearness and simplicity, and by the cautious moderation of his general principles. He became likewise a favourite practitioner in that rich and active city, and his business extended every year during his whole stay in Glasgow. Thus the greatest part of his time was taken up in the practice of medicine, or in increasing his stock of medical knowledge with a view to the improvement of his lectures. Chemistry, as far at least as he was professionally concerned, constituted but a secondary object. This may serve, in some measure at least, to explain the seemingly unaccountable fact, that he never attempted to enter that vast and tempting field of investigation which he had laid open.

It was during this period, however, that he investigated and brought to maturity another discovery of the utmost importance, we mean his theory of *latent heat*; a discovery which constitutes the foundation of the whole doctrine of heat as at present taught by chemists, and which has been attended with more beneficial effects to the world than any other discovery made during the 18th century; since it occasioned the improvements in the steam engine by Mr Watt, an instrument which has operated a complete change in our manufactures. The decisive experiment was made in 1761, and Dr Black drew up an account of this theory, and read it to a literary society in Glasgow on the 23d April 1762. No account of this theory was ever published by its author; but ever after it made a most important part of his chemical lectures. It became in consequence soon generally known in every part of Europe.

About this time likewise he made a set of experiments, to determine whether the expansions of the thermometer corresponded correctly with the increase of heat. He satisfied himself that they did so, and that the thermometer measured the increase of temperature correctly. The result of his experiments was read to the literary society of Glasgow on the 28th March 1760.

In the year 1766, Dr Cullen, chemical professor in Edinburgh, was appointed professor of medicine, and Dr Black, with the unanimous approbation of the city and university, was pitched upon as his successor. In this new scene, his talents were more conspicuous, and more extensively useful. The celebrity of the medical school of Edinburgh brought him pupils from all quarters, while the increasing importance of chemistry, both in the eye of the philosopher and manufacturer, made the number of chemical students increase every year. Dr Black, deeply impressed with the importance of the station which he filled, devoted himself completely to the improvement of his lectures on the elements of chemistry. His great object was to make them intelligible to all his students, however defective their previous education had been. He never ventured to indulge in hypothesis or conjecture, neither did he introduce any refined speculations, or touch upon those topics that would

have required previous reading and study. He confined himself entirely to matters of fact, and illustrated his lectures by plain and beautiful experiments, the best adapted for the subject under discussion, and just sufficient for his purpose. There was no parade of apparatus, nor brilliant display of showy but useless experiments; every thing appeared in its proper place, and exactly suited the object in view, the conveying to his pupils an exact knowledge of the subjects under discussion. His manner was remarkably pleasing; his voice was low, but fine and distinct; his elocution was slow, but graceful; and his style possessed a simplicity and elegance which has rarely been surpassed. He became a favourite professor, and was undoubtedly one of the greatest supporters of the celebrity of the Edinburgh medical school.

He filled the chemical chair in Edinburgh for nearly thirty-three years; and in the whole of that period, during which the science had advanced with unexampled rapidity, and had undergone a complete revolution, his reputation as a lecturer had been continually increasing; and though he added but little to the stock of chemical knowledge by his own discoveries, he made his lectures keep pace with the progress of the science, and even embraced and taught the antiphlogistic doctrines.

Owing partly, perhaps, to indolence, but chiefly to the delicate state of his health, he was obliged to remain a spectator of the brilliant discoveries in pneumatic chemistry, while he abstained from attempting to traverse the brilliant career which he himself had thrown open. About the year 1793, his health began to decline. He was unable to continue the gentle exercise which had so long prevented the approach of any serious disease. The fatigue of performing the experiments in his class he found too much for him, and he was obliged to get an assistant to take that labour off his hands. In 1796, he found the labour of lecturing beyond his strength, and got a successor appointed to relieve him of a part of the drudgery. Next year he hardly attempted to lecture at all, or at least delivered only a part of the course; and, unless our recollection fail us, 1797 was the last year that he read lectures in the university of Edinburgh. As he advanced in years, his constitution, which had always been weak, became more delicate and frail, so that every cold he caught occasioned some degree of spitting of blood. Yet he seemed to have this unfortunate disposition of body always under command, so that he never allowed it to proceed far, or to occasion any distressing illness; and he thus spun his thread to the last fibre; and even this does not seem to have broken, but merely to have ended. "He guarded against illness," says his relation Dr Ferguson, "by restricting himself to a moderate, or I should rather call it an abstemious diet; and he met his increasing infirmities with a proportional increase of attention and care, regulating his food and exercise by the measure of his strength. It is wonderful with what skill and success he thus made the most of a feeble constitution, by thus preventing the access of disease from abroad. He enjoyed a health which was feeble, indeed, but scarcely interrupted, and a mind ever undisturbed, in the calm and cheerful use of all his faculties. A life so prolonged had the advantage of present ease, and the prospect, when the just period should arrive, of a calm dissolution." His only apprehension was, that of a long continued sick-bed; and this, perhaps, less from any selfish feeling, than from the humane consideration of the trouble and distress occasioned to attending friends; and never

was this modest and generous wish more completely gratified.

On the 26th November, 1799, and in the 71st year of his age, he expired, without any convulsion, shock, or stupor, to announce or retard the approach of death. Being at table with his usual fare, some bread, a few prunes, and a measured quantity of milk diluted with water, and having the cup in his hand when the last stroke of his pulse was to be given, he set it down on his knees, which were joined together, and kept it steady with his hand, in the manner of a person perfectly at ease; and in this attitude expired, without spilling a drop, and without a writhe in his countenance; as if an experiment had been required, to shew to his friends the facility with which he departed. His servant opened the door to tell him that some one had left his name; but, getting no answer, stepped about half way up to him, and seeing him sitting in that easy posture, supporting his basin of milk with one hand, he thought that he had dropped asleep, which had sometimes happened after meals. He went back, and shut the door; but before he got down stairs, some anxiety, which he could not account for made him return back and look again at his master. Even then he was satisfied, after coming pretty near him, and turned to go away; but again returning, and coming quite close to him, he found him without life.

Such was the career of Dr Black, one of the greatest ornaments that the university of Edinburgh ever possessed. His mind was without doubt of the first cast, and endowed with an originality of thinking, and a patience of investigation, that fitted it for the most splendid undertakings. His imagination either was not vigorous, or he had brought it under the most complete controul; for no man was ever a greater enemy to wild and extravagant speculations and hypotheses, and no man ever deserved greater confidence as a sound philosopher, and an accurate reasoner. He carried his modesty rather to too great a length, and appeared too careless of his reputation as a discoverer, and a chemical reformer. Whether this was owing to a timidity of disposition, to indolence, or to want of health, it was equally unfortunate for himself, and for the literary world; and prevented him from occupying that place in the foremost rank of chemical discoverers, which nature obviously intended him to fill. The late Professor Dr John Robison, who knew him intimately and affectionately, assures us, that want of health alone prevented him from exposing the conduct of Mr Lavoisier, and vindicating his undoubted claim to his own discoveries. He undertook the task, and began it repeatedly; but his anxiety never failed to bring on a fit of illness, which obliged him to relinquish it. What reason he had to be dissatisfied with Lavoisier, or what private steps that celebrated philosopher may have taken to detract from Dr Black's reputation, we pretend not to say. Lavoisier certainly did Dr Black ample justice in the first treatise on chemistry which he published; for the whole treatise is little else than a history of Dr Black's discoveries with respect to the alkalis and lime, of the controversy which these discoveries occasioned in Germany, and a recitation of his own experiments, which convinced him of the truth of Dr Black's opinions. Of Dr Black's discoveries in other branches of the science, Lavoisier could not be supposed to know much with accuracy; for Dr Black had published nothing respecting them himself, and those writers who had touched

upon these subjects, whether in Britain or on the continent, had been either silent with respect to Dr Black's merit as an original discoverer, or arrogated to themselves an equal claim to originality with Dr Black himself.

As to Dr Black's private character, it was, in the highest degree, amiable and excellent. His temper was mild and placid; his disposition serious but cheerful. His sense of propriety was extremely acute, and all his actions were obviously guided by it. This appeared to a striking degree in his dress, in his house, at his table, in company, and in his lecture room. Every thing was done at its proper time; every thing was found in its proper place. He was never in a hurry, but always appeared to have leisure at command; and he was always happy to see a friend, and to enter into conversation on general subjects. His acquaintances sometimes accused him of penuriousness; but Dr Ferguson, who was his near relation, and had the best opportunity of knowing his character, directly denies the charge; and Professor Robison has given such instances of a contrary conduct, as seem totally incompatible with such a disposition. His person was rather above the middle size; he was of a slender make; his countenance was placid, and exceedingly engaging.

But in giving the history of a literary character, the points of greatest importance are undoubtedly his works, which constitute the grand eras of his life. As a philosopher, the additions which he made to the stock of our knowledge, and the exertions which he made towards the advancement or the general diffusion of the sciences, constitute the great characters which distinguish him from the generality of mankind. We must not, therefore, quit Dr Black, without pointing out his literary labours more particularly, and endeavouring to estimate the obligations which chemistry lies under to him for his sagacity and discoveries.

If we were to estimate the merits of a literary man from the bulk of his writings, Dr Black would be rated very low. The only pieces which he published in his life-time were four essays: 1st, His inaugural dissertation, entitled, *De acido a cibus orto et de magnesia*; 2d, *Experiments upon magnesia alba, quicklime and other alkaline substances*, first published in the *Edinburgh Physical and Literary Essays* in 1755, and afterwards in a separate form by Mr Creech; 3d, *Observations on the more ready freezing of water that has been boiled*, published in the *Philosophical Transactions* of London for 1774; and, 4th, *Analysis of the waters of some boiling springs in Iceland*, published in the second volume of the *Edinburgh Transactions*. After his death, his manuscript lectures were revised by Professor Robison, and published by his executors in two quarto volumes. This book possesses great merit, especially the first part of it which treats of *Heat*. The simplicity of the style, and the exquisite taste and propriety displayed in the illustrations, cannot be too highly praised; though, as a whole, it is certainly very different from what it would have been, had it received the last corrections of the author himself. The arrangement in many parts is extremely defective; and, as a collection of chemical facts, it is nearly twenty years behind the period at which it finally appeared. Had it been published in 1788, it would have contributed essentially to promote the progress of the science; it would have increased the reputation of its author, and been a highly popular book even in the hands of the students; but, in 1803,

its place was supplied by others, exhibiting a fuller detail of chemical facts, and bringing the progress of the science down to the date of their publication.

In taking a view of these different publications, we may pass over the first entirely. The second was, in fact, a repetition, or rather a more complete investigation of the different points touched upon in the inaugural dissertation.

1. The essay on magnesia and quick-lime embraces two distinct objects: 1st, The properties of magnesia; 2d, An investigation of what constitutes the difference between quick lime and limestone, between the mild and caustic alkalies.

Magnesia had been discovered by a Roman canon, at Rome, about the beginning of the last century, and a few of its properties had been ascertained by Frederick Hoffmann; but chemists, in general, considered it as a variety of lime, and none knew the peculiar characters by which it is distinguished. Dr Black ascertained its properties with precision, and demonstrated that it is a peculiar earth. To him, therefore, in reality, we are indebted for our knowledge of magnesia. He combined magnesia with sulphuric, nitric, muriatic, and acetic acids, and ascertained the properties of the salts formed; compared them with similar salts of lime, and pointed out the essential differences. He determined the effect of heat upon magnesia; shewed that it deprived it of a quantity of air; that the magnesia continued still tasteless and insoluble in water; that it combines with acids without effervescence, and forms with them the very same salt as common magnesia. He determined the affinity of magnesia for acids, when compared with lime and alkalies; and pointed out the difference between it and alumina, and the earth of bones.

The investigation and determination of the properties of magnesia, though an object of great importance, sinks into insignificance when compared with the object of the second part of this important essay, to ascertain the difference between quick-lime and limestone, mild and caustic alkalies, common and calcined magnesia. By the most simple but decisive experiments he demonstrated, that limestone and the mild alkalies contain a quantity of air fixed in them; that this air makes its escape when they are dissolved in acids; that it is dissipated when limestone is burnt; that alkalies are rendered caustic by being deprived of it; that lime has a greater affinity for it than alkalies; that it takes it from them when mixed with them. Hence the reason why quick-lime renders alkalies caustic, while, by the process, it is converted itself into limestone. The caustic alkalies, quick-lime, and calcined magnesia, are the substances in a pure state; hence the reason of the activity which they possess, and of their dissolving in acids without effervescence. This air he called *fixed air*, because it exists fixed in their bodies. He inferred, that it possessed peculiar properties; that it differed from common air; that it existed in the atmosphere; and that there are different kinds of air possessed of peculiar properties. But he made no experiments himself on the subject, but drew his inferences from common observations; of a kind, however, sufficiently decisive. He even shewed, that it acted as an acid; that it combined with alkaline substances in different proportions; and he announced his intention of prosecuting the subject at greater length hereafter; a promise, however, which he never fulfilled. It is impossible to bestow too high praise upon Dr Black's paper on magnesia and quick-

lime. The modest simplicity of the narration, the number and conclusiveness of the experiments, the sagacity with which the proper inferences are drawn, the accuracy and decisiveness of the reasoning, and the small number of mistakes into which the author fell in prosecuting a subject entirely new and quite the opposite of the preconceived opinions of chemists, are all admirable, and account sufficiently for the high rank to which they immediately raised the author among chemists. Indeed, we know of no chemical dissertation whatever that will stand a comparison with the essay of Dr Black. Mr Lavoisier's papers are much more elaborate, at least in appearance, and the consequences which he deduces from his experiments are, perhaps, of more importance than even the discoveries of Dr Black; but his discoveries were the result of a whole life, spent in the most laborious industry, whereas Dr Black's great discovery was completed at the age of twenty-five.

Soon after the publication of Dr Black's essay, Mr Meyer, an apothecary at Osnaburgh, published a dissertation, in order to explain the differences between limestone and quicklime, the caustic and mild alkalies. His conclusions were quite different from those of Dr Black. According to him, limestone combines in the fire with a peculiar acid, which he called the *acidum pingue*, or *causticum*. To this acid it owed the peculiar acrid properties which it acquired by calcination. Alkalies had a stronger affinity for this acid than lime. Hence, when potash and quicklime are mixed, the lime loses its acid, and becomes tasteless and insoluble in water; while the alkali unites with the acid and becomes caustic. Meyer's hypothesis being contrasted with Dr Black's theory, which soon became known in Germany, occasioned a violent controversy, which lasted some years. Jacquin, botanical professor at Vienna, published a Latin dissertation in defence of Dr Black's doctrine in 1769. This was opposed, in 1770, by Dr Crans, physician to the king of Prussia, who defended the hypothesis of Meyer in a very elaborate treatise. In 1774, Lavoisier published a treatise on the subject. He repeated the experiments of Dr Black and his disciples, and confirmed them in every particular. Since that period, Dr Black's theory of causticity, and his doctrines respecting fixed air, have been universally admitted by the chemical public.

Dr Black's essay drew the attention of philosophers to the elastic fluids, and in particular to *fixed air*, which he had shown to act so important a part in nature. Dr Macbride of Dublin was the first who wrote on the subject. His essay appeared in 1764. He examined the fixed air evolved during fermentation, and pointed out its properties in retarding putrefaction. But it was Mr Cavendish who first examined the properties, and pointed out the characters of fixed air. His essays on the subject were published in 1766 and 1767. Dr Priestley followed soon after, and laid open the different elastic fluids in succession. Thus Dr Black's discovery is not only important in itself, but it acquires additional value, because it led the way to pneumatic chemistry, and was therefore the foundation of the complete revolution which the science underwent.

2. The paper on the freezing of boiled water, published in the *Philosophical Transactions*, is very short, and requires but little notice. He found, that water which has been newly boiled always freezes sooner than common water. The reason, he says, is, that boiled water cannot be cooled lower than 32° , without beginning to freeze; whereas common water may be cooled several

degrees lower, without losing its fluidity. This difference he ascribes to the boiling, which has deprived this water of its air. Hence, when exposed to the air, that elastic fluid begins to enter, and occasions a constant agitation, which, though imperceptible to us, is yet sufficient to prevent the water from being cooled lower than 32° without freezing. This explanation is simple and ingenious, and probably correct. Though some of the experiments of Sir Charles Blagden, on the cooling of water below the freezing point, without losing its fluidity, appear at first sight incompatible with it.

3. The analysis of the Geyser and Reykum waters, which Dr Black published in the second volume of the *Edinburgh Transactions*, is one of the finest specimens of the analysis of mineral waters which has yet appeared. Dr Black has contrived to throw an interest on his subject, of which one would hardly have conceived that it would have admitted. This appears in a very striking point of view, when compared with the essays of Bergman, Klaproth, Fourcroy, Vauquelin, or any other of the consummate masters of the art of analysing mineral waters. The interest which we take in the analysis of Dr Black, is much greater than in that of any other person. The analysis is remarkably correct, and the methods followed are the best that we are yet acquainted with; though his directions for preparing the filters can scarcely be followed at present. His mode was tedious; and his reliance upon the filtre much greater than it ought to have been. Chemists at present seldom trust to experiments made by weighing filters. They are so apt to change their weight, and their tendency to absorb moisture is so great, that they cannot be easily weighed in a delicate balance. A filtre, weighing thirty grains, if dried at the fire, will absorb half a grain of moisture before you can weigh it.

4. The only part of the posthumous work, entitled Dr Black's *Lectures*, that requires animadversion, is his doctrine of *latent heat*, contained in the first part of that book. This doctrine he brought to maturity while in Glasgow. He read an account of it to a philosophical society in that city, in the year 1762. Ever after it was taught by him with great care, and sufficiently in detail, constituting indeed one of the most important and interesting parts of his course. This theory is not only in itself highly beautiful and valuable, as it constitutes the basis of the whole doctrine of heat, one of the most instructive branches of chemical science; but it has another claim upon our attention,—it led to Mr Watt's improvement of the steam engine, which has produced such mighty changes in our system of mining and in our manufactures, and which has so enormously increased the powers and the resources of man. Dr Black's two discoveries hold a most interesting position; the first occasioned a complete revolution in the science of chemistry; the second an equally complete revolution in some of our most important arts and manufactures. The theory of latent heat, which Dr Black deduced from an attentive observation of some of the most common phenomena of nature, and from some experiments of Fahrenheit, may be stated in a few words. When ice melts, it combines with a quantity of heat which enters into it, and remains in it without increasing its temperature. Hence it was called *latent*. When water freezes, it parts with the whole of this latent heat; and it cannot freeze till it does so. Hence the slowness of the processes of freezing and melting. Water then is ice, combined

with a certain quantity of heat. In like manner, when water is converted into *steam*, it combines with a quantity of heat; and when steam is condensed into water, it parts with a quantity of heat. In general, when solids are converted into liquids, they unite with a quantity of latent heat; and when liquids are converted into elastic fluids, they likewise combine with latent heat. This theory was demonstrated by the most obvious, but decisive experiments, and it was applied, with much sagacity, to explain some of the most important phenomena of nature. In his experimental investigations of the quantity of latent heat in different bodies, Dr Black was much assisted by his two celebrated pupils, Mr Watt and Dr Irvine. He first suggested also the curious fact, that bodies differ in their capacity for heat; that is to say, that the same quantity of heat does not produce the same change of temperature upon different bodies. Thus it requires much more heat to raise a pound of water 100 degrees, than is necessary to produce the same change of temperature on a pound of mercury. This subject was carried much farther by Dr Irvine, who made some curious discoveries respecting it, and even applied it to explain Dr Black's great discovery of *latent heat*. His explanation was adopted by several ingenious philosophers; and there are still some persons who consider Dr Irvine's explanation as preferable to Dr Black's. Dr Black himself stated some objections to Dr Irvine's explanation, with his usual modesty, which appear to be fatal to it. Dr Crawford afterwards investigated the capacity of different bodies for heat with much industry and success, and founded on it his ingenious explanation of the source of animal heat.

Though Dr Black never himself published any account of his peculiar opinions respecting *latent heat*, they soon came to be generally known all over Europe, in consequence of the great concourse of students from all quarters that attended the chemical class at Edinburgh. Various dissertations, both respecting latent heat, and the capacity of bodies for heat, were published at different times, and in different places. The authors seldom or never refer to Dr Black; but tacitly assume to themselves the merit of originality. And, in consequence of Dr Black's indolence and carelessness, it is now almost impossible to determine how far these claims were well or ill founded. That Dr Black was the original discoverer, and that he had taught the doctrine publicly, at least ten years before any competitor appeared, is perfectly established. But whether the subsequent authors derived their information from students who had attended Dr Black's class, or had stumbled themselves upon the theory which they published, it is now very difficult to say. The first publisher on the subject was Mr Wilcke of Sweden, whose dissertation on the capacity of different bodies for heat, appeared in 1773. Lavoisier and Laplace published their experiments on the heat necessary to melt various bodies, and upon the heat

evolved during combustion, about the year 1777. Mr Cavendish, in a dissertation published about the year 1785, claims as his own the discovery of latent heat; but says in a note, that he understood that Dr Black teaches a similar doctrine. As to the attempt of De Luc, in his *Idées sur la Météorologie*, to claim the original discovery of latent heat, it does not seem entitled to any attention whatever; and has been sufficiently exposed by Mr Watt and Professor Robison. Mr Cavendish, from the character of the man, and the great sagacity which he possessed, would be the most likely to have hit upon the theory. But it became so generally known, and so much had been written upon it before his claim appeared, that it is impossible to doubt that he had imbibed his opinions respecting heat from these publications; and certain opinions respecting heat being adopted, the doctrine of latent heat followed as an easy consequence. Upon the whole, Dr Black's originality admits of no doubt; and had he published an essay on the subject, as he did with regard to fixed air, no competitor whatever would have appeared; and his rank as a discoverer, at least among the chemists of the continent, would have stood higher than it does at present.

5. We cannot conclude this article, without mentioning a circumstance regarding Dr Black, which does not appear to be generally known. We relate it on the authority of the late Benjamin Bell, Esq., surgeon in Edinburgh, who had it, as he informed the writer of this article, from the late sir George Clerk of Pennyquick, a particular friend of Dr Black, and an eye-witness to the circumstance. When Mr Cavendish, in 1766, ascertained the specific gravity of hydrogen gas, it occurred to Dr Black, that it might be employed to raise weights in the atmosphere. He procured the alantois of a calf, filled it with hydrogen gas, and found, that the bag, thus filled, was lighter than air, and would rise to the ceiling of the room. He invited a number of his friends to supper, and told them, that he had a curiosity to shew them. When the company met, he produced his prepared alantois, and, to the surprise of all present, it ascended, and remained attached to the ceiling of the room. At first, they supposed that a fine thread had been attached to it, and that some person in the room above had drawn it by that means to the ceiling. But an actual inspection convinced them, that this solution was erroneous. Dr Black then explained to them the way in which it was filled, and pointed out the useful purposes to which such contrivances might be applied. If this statement be correct, and, from the source of the information, there seems reason to rely upon it, Dr Black was in reality the discoverer of the air-balloons; and he made the discovery nearly fifteen years before the idea suggested itself to M. Montgolfier. Unfortunately, all the gentlemen mentioned by Mr Bell, as having been present at the exhibition, are now dead; so that it is impossible to authenticate it by any more direct testimony. (c)

BLACK SEA.

THE Black Sea, formerly called the Euxine* Sea, is an immense inland sea, situated between Europe and Asia, and connected with the Mediterranean by the Straits of Constantinople.

By comparing the accounts of this sea, as given by ancient authors, with the limits assigned to it by recent observations, it appears unquestionable, that it has sustained a most singular diminution, in consequence of some great subterranean convulsion.

From the topographical descriptions of the Black Sea, as collected by Valerius Flaccus, from the ancient accounts of the voyages of the Argonauts, it appears, that the gulls and bays of this lake were extremely deep; and that, in conjunction with the Palus Meotidis, it extended far towards the north, and almost equalled the Mediterranean in magnitude. In the time of Homer, according to Strabo and Eustathius, the Euxine Sea was regarded as the greatest of all the inland seas; and received the name of *πρωτος*, on account of its superior magnitude. Herodotus makes the length of the Euxine Sea, from the Cyanean Isles (now the Pavorante) to the river Phasus, 11,100 stadia, or nearly 17 degrees and a half. Procopius reckons the distance from Chalcedon to the Phasus at 50 days journey, for a good walker, which, at the rate of nine leagues a-day, will make the distance equal to 18 degrees; a result which coincides remarkably with that of Herodotus. As the utmost extent of this sea, however, in the best modern charts, does not exceed 12 degrees and a half, we are entitled to conclude, that it formerly covered the low grounds which stretch towards the base of the mountains of Caucasus.

The north and west coast of this sea seem to have undergone very remarkable changes. The line of its greatest width has undoubtedly varied; and the immense volume of waters which is rolled from Asia and Europe into this capacious reservoir, seem to have completely changed the outline of its coast, and filled up the deep gulfs which indented its shores. The southern coast, which consists chiefly of calcareous rocks, upon which the sea reposes, to a great depth, has suffered but few changes, excepting at the mouths of the rivers; and hence the geographical descriptions of this part of the Black Sea, as given by ancient authors, are more easily reconciled with modern observations.

From these indications of extensive changes, as well as from the testimony of ancient authors, it would appear, that the Sea of Aral and the Caspian Sea once formed an immense lake, joined by a strait to the Palus Meotis and Euxine Sea; and that this huge collection of water was separated from the Mediterranean by a narrow isthmus, formed by the Cyanean Isles. An eruption of these volcanic islands is supposed to have formed an outlet for the exuberant waters of the Euxine, which rolled its torrent with irresistible impetuosity into the Propontis, and afterwards into the Mediterranean, and deluged the low plains of Asia Minor,

Thrace, Greece, Egypt, and Libya. The effects of this dreadful inundation are recorded in the monuments, the traditions, the poetry, the history, and the chronology of these ancient nations. The Samathracians, according to Diodorus (lib. v. cap. 47.) ascribed this deluge to the opening of the mouth of the Bosphorus. Their fishermen dragged out, in their nets, the capitals of columns that belonged to the cities which had been submerged; and, in the time of Diodorus, they offered sacrifices upon altars erected on the line which formed the limits of the inundation. Ister, an ancient author quoted by Eustathius, mentions some great inundations, one of which opened the canal of the Hellespont that separated Europe from Asia; and Strabo and Xanthus bear testimony to the same event, which seems to have happened about 1529 years before Christ.

We shall now proceed to state the evidence in support of this remarkable fact, as collected from the observations of modern naturalists and travellers.

According to Tournefort, (*Voyage au Levant* tom. ii. p. 124, 125, &c.) the Black Sea appears to have been an immense lake, formed by the waters of innumerable rivers, and unconnected with the Mediterranean, and could only empty itself through the Thracian Bosphorus. The mountains which are interposed between it and the Caspian Sea, prevent any opening towards the east. The waters of the Sea of Azof fall into the Black Sea, from north to south, and oppose any passage in that direction. The rivers of Asia push the waters of the Black Sea from south to north. The Danube impels them from the west. It is therefore at the isles of Cyaneæ alone, between the lighthouses of Europe and Asia, which are situated at the mouth of the Bosphorus, where the waters of the Black Sea could hollow out the earth, and force a passage into the Propontis.

Buffon (*Hist. Nat.* tom. ix.) has adduced innumerable facts to prove, that the Mediterranean Sea, the Black Sea, the Caspian Sea, and the Sea of Aral, have at one time been immense lakes; that the Caspian Sea was formerly of great extent, and that the Mediterranean was once much smaller than it is at present; that the Aral, the Caspian, and the Black Sea, formed only one lake before the opening of the Bosphorus; and that the Mediterranean, after this opening, was augmented in the same proportion as that lake had diminished.

"Siberia, Asia, the Red Sea, &c.," says Pallas, (*Travels*, tom. ix. p. 163.) "present evident marks of this deluge, of which all the ancient people of Asia, the Chaldeans, the Persians, the Indians, the Thibetans, and the Chinese, have preserved the remembrance, and which they have fixed within a few years of the Mosaic deluge. Europe, and the low lands of Asia, have since suffered considerable changes by other inundations, sometimes arising from submarine eruptions, sometimes from the sudden overflow of the great inland seas, as the Mediterranean and the Euxine, which

* The term Euxine is derived from *αἴζηνος*, *inhospitable*, the epithet given by the ancients to this sea. Hence Ovid,

Frigida me cohibent Euxini littora Ponti:
Dicitur ab antiquis ΑΞΕΝΟΣ ille fuit. OVID lib. iv. Trist. Eleg. iv.

have left dry extensive plains covered with mud; and sometimes to irruptions of the sea, increased by enormous submarine eruptions.

"The opinion of the indefatigable Tournefort and Buffon," the same naturalist elsewhere observes "upon the ancient state of the Black Sea, and its communication with the Caspian, has been more and more confirmed by the observations of travellers. The sea monsters, the fish, and the marine shells, which the Caspian has in common with the Black Sea, render this communication extremely probable; and the same facts prove also, that the lake of Aral was once joined to the Caspian. In the 3d and 7th volumes of my Travels, I have traced the ancient extent of this sea over all the desert of Astracan and that of Jaik; by that appearance of coasts with which the elevated plains of Russia limit the desert, by the state and the fossil productions of this ancient coast, and by the salted mud mixed with calcined sea shells which cover all the surface of the desert."

The Cyanean Isles, at the mouth of the Bosphorus, have been recently examined by Olivier and Choiseul Gouffier, who discovered that these islands were volcanic. "At the mouth of the canal, on both sides of the Bosphorus," says Olivier, (*Voyage*, tom. i. p. 69.) "we were struck with the marks of a volcano of several leagues in extent. Every where we observed the rocks more or less altered or decomposed; every where we found incontestible marks of the action of subterranean fires. We observed jaspers of different colours, carnellians, agates, and chalcedonies, among porphyries, more or less changed; a breccia, with little solidity, and almost decomposed, formed by fragments of trap, agglutinated by calcareous spar; a beautiful porphyry at the base of a rock of greenish trap, coloured by copper; and through an extent of half a league we saw a hard rock of trap, of a greenish blue, equally coloured with copper." In quoting this able traveller, on the volcanic nature of the banks of the Bosphorus, we ought at the same time to state, that he entertains a different opinion from other naturalists respecting the formation of that strait. He does not believe that the waters of the Black Sea were once more elevated, and that they opened for themselves a passage by the Bosphorus; but he supposes, that the Propontis, the Euxine, and the Mediterranean, always communicated with each other. He is of opinion, that the Caspian was of much greater extent; that it communicated with the Sea of Azof, and that their waters had the same level; and he attributes to the currents of the Don, the Kouban, and the Wolga, the filling up of the canal, and the consequent separation of the two seas. After this separation, he supposes that the Black Sea has not changed its level, because it receives more water than it wastes by evaporation; and that the Caspian Sea has sunk above 60 feet, because it does not receive a quantity of water sufficient to supply what is lost by evaporation; and that it gradually diminished, till an equilibrium existed between the supply and the evaporation.

M. Bergman,* who travelled into the country of the Calmucs in 1802 and 1805, has collected a vast number of facts, to prove that the Asiatic part of the steppes of the Calmucs was once covered with water, and that the Caspian and Black Seas were formerly united.

We shall now conclude this part of the article, by presenting our readers with the interesting description of the appearance of the Thracian Bosphorus, and the nature of the Cyanean Isles, and the adjoining strata, as given by the ingenious Dr Clarke, in his *Travels* into different countries of Europe, Asia, and Africa.

When Dr Clarke, in his voyage from Incada to Constantinople, first discovered the light tower on the European side of the Bosphorus, it appeared situated at the base of an immense range of mountains. The whole coast, on both sides, opened with a degree of indescribable grandeur, and resembled a stupendous wall, opposed to the great bed of waters, in which the mouth of the Bosphorus was like a small crack or fissure occasioned by an earthquake.

"As we entered the straits," says Dr Clarke, "a miserable lantern, placed upon a tower on either side, presented to us all that was intended to serve as a guidance for seamen during the night. Never were light-houses of more importance, or to which less attention has been paid. An officer of the customs put off from the shore in his boat; but contented himself with merely asking the name of the captain, and did not come on board. After passing the light-houses, there appeared fortresses, the works of French engineers; and their situation, on rugged rocks, had a striking effect. Presently, such a succession of splendid objects was displayed, that, in all the remembrance of my former travels, I can recall nothing with which it may be compared. A rapid current, flowing at the rate of a league an hour, conveyed us from the Black Sea. Then, while we were ruminating upon the sudden discharge of such accumulated waters by so narrow an aqueduct, and meditating the causes which first produced the wonderful channel through which they are conveyed, we found ourselves transported, as it were, in an instant, to a new world. Scarcely had we time to admire the extraordinary beauty of the villages, scattered up and down at the mouth of this canal, when the palaces and gardens of European and Asiatic Turks, the villas of foreign ambassadors, mosques, minarets, mouldering towers, and ivy-mantled walls of ancient edifices, made their appearance. Among these we beheld an endless variety of objects which seemed to realise tales of enchantment; fountains and cemetries, hills, mountains, terraces, groves, quays, painted gondolas, and harbours, presented themselves to the eye, in such rapid succession, that, as one picture disappeared, it was succeeded by a second, more gratifying than the first.

"On the following day, we were determined to adventure an excursion as far as the islands anciently called Cyaneæ, or Symplegades, which lie off the mouth of the canal. The accurate Busbequius confessed that, in the few hours he spent on the Black Sea, he could discern no traces of their existence; we had, however, in the preceding evening, seen enough of them to entertain great curiosity concerning their nature and situation, even in the transitory view afforded by means of our telescopes. Strabo correctly describes their number and situation. 'The Cyaneæ,' says he, 'in the mouth of Pontus, are two little isles, one on the European, and the other on the Asiatic side of the strait, separated from each other by twenty stadia.' The more ancient accounts, which represented them as some-

* See *Journal Universelle de Littérature, de Halle*, March 1805, No. 56, p. 441, &c

times separated, and at other times joined together, was satisfactorily explained by Tournefort, who observed, that each of them consists of one craggy island, but that, when the sea is disturbed, the water covers the lower parts, so as to make the different points of either resemble insular rocks. They are, in fact, each of them joined to the main land by a kind of isthmus, and appear as islands when this is inundated, which always happens in stormy weather. But it is not clear that the isthmus, which connects either of them with the continent, was formerly visible. The disclosure has been probably owing to that gradual sinking of the level of the Black Sea, before noticed. The same cause continuing to operate, may hereafter lead posterity to marvel what is become of the *Cyanææ*; and this may also account for their multiplied appearance in ages anterior to the time of Strabo. The main object of our visit was not, however, the illustration of any ancient author in this particular part of their history, but to ascertain, if possible, by the geological phenomena of the coast, the nature of a revolution which opened the remarkable channel at the mouth of which those islands are situated.

“Some time before we reached the mouth of the canal, steering close along its European side, we observed the cliffs and hills, which are there destitute of verdure, presenting, even to their summits, a remarkable aggregate of enormous pebbles, that is to say, heterogeneous masses of stony substances, rounded by attrition in water, and imbedded in a hard natural cement, yet differing from the usual appearance of breccia rocks; for, upon a nearer examination, they appeared to have undergone, first, a violent action of fire, and secondly that degree of friction, by long contact in water, to which their form was due. Breccia rocks do not commonly consist of substances so modified. The stratum formed by this singular aggregate, and the parts composing it, exhibited, by the circumstances of their position, striking proof of the power of an inundation; having dragged along with it all the component parts of the mixture, over all the heights above the present level of the Black Sea, and deposited them in such a manner, as to leave no doubt concerning the torrent which passed towards the sea of *Marmora*. As in a field of corn long agitated by a particular wind, we see the whole crop incline towards one direction; so, at the mouth of the canal of Constantinople, all the strata of the mountains, and each individual mass composing them, lean from the north towards the south. On the point of the European lighthouse we found the sea, still tempestuous, beating against immense rocks of hard and compact lava; these had separated prismatically, and exhibited surfaces tinged by iron oxide wherever a division was effected.

“From this point we passed to the *Cyanean Isle*, on the European side of the strait, and there landed. The structure of the rock, of which the island consists, corresponds with the nature of the strata already described; but the substances composing it were perhaps never before associated in any mineral aggregate. They all appear to have been more or less modified by fire, and to have been cemented during the boiling of a volcano. In the same mass may be observed fragments of various coloured lava, trap, basalt, and marble. In the fissures are found agate, chalcedony, and quartz, but in friable and thin veins, not half an inch in thickness, and apparently deposited posterior to the settling of the stratum, of which the island consists. The agate appeared in a

vein of considerable extent, occupying a deep fissure not more than an inch wide, and coated by a green substance, resembling some of the lavas of *Ætna*, which have been decomposed by acidiferous vapours. Near the same vein appeared a substance resembling native mercury, but in such exceedingly minute particles, in a crumbling matrix, that it was impossible to preserve a specimen. The summit of this insular rock is the most favourable situation for surveying the mouth of the canal; which thus viewed has the appearance of a crater, whose broken sides opened towards the Black Sea, and, by a smaller aperture, towards the Bosphorus. The Asiatic side of the Strait is distinguished by appearances similar to those already described; with this difference, that, opposite to the island, a little to the east of the Anatolian light house, a range of basaltic pillars may be discerned, standing upon a base inclined towards the sea; and when examined with a telescope, exhibiting very regular prismatic forms. From the consideration of all the preceding observations, and comparing events recorded in history with the phenomena of nature, it is perhaps more than a conjectural position, that the bursting of the Thracian Bosphorus, the deluge mentioned by Diodorus Siculus, and the draining of the waters which once united the Black Sea to the Caspian, and covered the great Oriental plain of Tartary, were all the consequence of earthquakes caused by subterranean fires, described as still burning at the time of the passage of the Argonauts, and whose effects are visible even at this hour.”

The Black Sea received its name from the darkness which often covers it, particularly during winter, in consequence of thick fogs and falling rains. This obscurity is often so great, that mariners are unable to see a cable's length from their vessels, and on these occasions the entrance of the Bosphorus is impracticable. Dr Clarke affirms, that there is no sea in which the navigation is more dangerous; that shallows hitherto unnoticed in any chart frequently occur when vessels are out of sight of land, and that dreadful storms come on so suddenly, and with such fury, that every mast is carried overboard almost as soon as the first symptom of a change of weather is observed. Admirals Priestman and Wilson, who commanded the Russian fleet, described the Black Sea as exhibiting tempests more horrible than any thing they had ever encountered in the ocean.

This account of the Black Sea is completely contrary to that given by Tournefort. “Whatever the ancients may have said,” observes this able naturalist, “the Black Sea has nothing black but the name; the winds do not blow there with more fury; and the storms are not more frequent than in other seas. We must pardon the exaggeration of the ancient poets, and particularly the chagrin of Ovid. The sand of the Black Sea, indeed, is of the same colour with the sand of the White Sea, and its waters are equally pure. If the coasts of this sea, in short, which are reckoned so dangerous, appear gloomy from a distance, it is owing to the woods which cover them, or the great distance which gives them the appearance of blackness. The sky here was so beautiful and so serene during the whole of our voyage, that we could not avoid giving the lie to Valerius Flaccus, the famous Latin poet, in describing the route of the Argonauts, who passed for the most celebrated sailors of antiquity, but who were only very little boys when compared with Vincent le Blanc, Tavernier, &c. This poet assures us, that the

sky on the Black Sea is always obscured with fogs." (*Voyage du Levant*, Lett. xvi. tom. iii. p. 1.) The same opinion is stated by Mr Thornton in his Survey of the Turkish Empire. "It is a notion," says he, "received among the Turks that the Black Sea is dangerous. To them indeed it is truly black; and it would even be so to British sailors in such vessels as the Turks use, and which are peculiar to that sea; they cannot lie to, and are consequently obliged to run before the wind, and if they miss a port, go on shore. It is not more stormy than other seas."

Besides being distinguished by the haziness of its atmosphere, and by the storms with which it is agitated, the Black Sea is remarkable for its extraordinary temperature. Ovid, during his residence on the Black Sea, had observed, the "*ingentem glacie consistere pontum*;" and Dr Clarke was informed by Captain Bergamini, that he was once detained *five months* in the mouth of the Danube by the freezing of the sea.

The Black Sea abounds with sea-worms, which gnaw the planks of vessels, and in the space of two years completely destroy the sides of the ships. These animals are four or five inches long. Their head resembles an arrow, and their body consists of a whitish mucilage. The only way of destroying them has been until lately, to lay up the vessels for two years to careen them, and to cover the sides with burning pitch and juniper wood. The vessels which navigate the Black Sea are now begun to be coppered, which is the only effectual remedy against the attack of these worms.

The force kept by the Russians in the Black Sea, consists of the flotillas of Nicolaïef and Sevastapool. The first of these comprehends 70 or 80 shallops decked and carrying guns, with some others which are row boats. The latter is composed of four vessels of the line, and four or five frigates. This naval force is not under the direction of the Admiralty of St Petersburg, but under an High Admiral stationed at Nicolaïef.

We shall now conclude this article, by giving some account of the commerce of the Black Sea, for which we are principally indebted to Mr Reuilly, who travelled along its shores so late as the year 1803.

"The storms frequent in the Black Sea," observes that learned traveller, "and the savage state of the people inhabiting its coasts, prevented the Greeks for a long time from visiting its shores. The expedition of the Argonauts is the first trace of navigation and commerce in that sea, which antiquity has transmitted to us.

This trade took place principally in the Oriental parts; but notwithstanding the establishment of several colonies upon its coasts, it was inconsiderable during the first ages of Greece, and under the empire of the Romans. It did not begin to flourish until the time of the crusades, when the Latins possessed themselves of Constantinople: at that time the Genoese and the Venetians carried on this trade with such considerable advantage, that the conquest of Egypt by the Arabs having entirely ruined the ancient commerce of Alexandria, the merchandise of India opened itself a new way to the European markets; they went thither sometimes by the Indies, and the Russian Sea, or were transported by caravans across Georgia and Mingrelia; sometimes by going up the Persian gulf, the Tigris, or the Euphrates; they went, by way of Armenia, to Trebizond, whither the Genoese and the Venetians went to meet them, for the purpose of supplying Europe with their commodities.

Jealousy, the inevitable consequence of the great advantages this commerce procured, was the occasion of some bloody wars between the Venetians and the Genoese, which terminated in the last becoming the masters; by contributing to the overthrow of the dominion of the Latins at Constantinople, profiting dextrously by the favour or the weakness of the Greek emperor, they obtained from them such advantages, that they had no longer any rivals. To secure to themselves this exclusive commerce, they fortified their settlement at Pera, established colonies on the coasts, principally in Crimea, and put their factories in a state of defence: Caffa was the principal city of their commerce with the East, and the port at which was deposited all the merchandise which had been transported to the Black Sea. The merchandise of India, Persia, and Arabia, came to Astracan, went again up the Volga, was carried afterwards by land as far as the Don, distant about sixty versts, conveyed by that river to Azof, and thence embarked for Caffa. The Genoese procured to themselves immense riches, and put themselves in a situation, notwithstanding the smallness of their territory, to hold rank among the first of the maritime powers. They enjoyed these advantages until the taking of Constantinople by Mahomet the Second, of which almost the immediate consequence was, their expulsion from the Crimea. With the annihilation of the power of the Genoese, ended the commerce of the Black Sea.

It is to be observed, that, at this epoch, the re-establishment of the ancient route by Alexandria, which took place under Tala-Eddin, had already turned that source of riches.

The progress of navigation, by the discovery of the route to India, and of America, gave a new spring to the mercantile spirit of the Europeans, lessening, in some degree, the regret which the loss of this ancient seat of their prosperity had occasioned, and turning their thoughts to the means of restoring that advantage. It was not until the beginning of this century that Peter the First, desirous to create commerce, unknown in his vast empire, saw the immense advantage it would derive from the possession of some ports in the Black Sea: he succeeded in the acquisition of Azof; but the misfortunes which he met with afterwards, and the peace of Prouth, was the occasion of his surrendering his conquests, and the advantages that might have been derived from them. Catharine the Second following the steps of this great legislator of Russia, had the glory of accomplishing the design his genius had conceived.

After two long wars, the Turks found themselves compelled to surrender to Russia a part of Lesser Tartary, and, at length, the Crimea; to allow them to establish in that quarter a navy, and to permit their flag the free passage of the Dardanelles.

Austria, the ally of Russia, has partaken of this last advantage, and these two nations alone carried on the commerce, always inconsiderable for want of means and of concurrence, until the time when, after the conquest of Egypt, the French government obtained, by its treaty of peace with the Porte, the free navigation of the Black Sea. It has been granted with the like facility to the other principal powers of Europe in such an extent, that the commerce of that sea may be considered to be absolutely free."

It would appear, from the principal treaty between England and Turkey, that we had a commercial footing in the Black Sea in the time of Queen Elizabeth or

James I. In the time of Charles II. the conditions of alliance with England were revised, and amplified in 1661-2, by the Earl of Winchelsea, and afterwards in 1675, by Sir John Finch. These treaties gave all the subjects and dependants of England permission to pass and repass with their merchandise into every part of the Ottoman dominions. All the particular privileges which belonged to the French, Venetian, or any other Christian nation, were conceded to the English. In 1799, the freedom of the Black Sea was again given to the English. On this occasion, Mr Smith observes, in the memorial which he presented to the Ottoman Porte, that, "by enabling the English navigator to penetrate the deep gulfs of the Black Sea, and thus rendering the remotest districts accessible to the English merchant, instead of the present languid routine of a single factory superintending two or three annual cargoes, assorted according to the limited consumption of the metropolis, with the refuse of which the provincial traders are scantily furnished at second and third hand, we shall see whole fleets laden with the richest productions of the Old and New World. British capital and credit would attract flourishing establishments in the solitary harbours of Anatolia, from whence the adjacent cities would receive less indirect supplies, and where the landholders would find more ready exchange for their produce. Sinope and Trebizond would again emulate the prosperity and population of Aleppo and Smyrna. The Abazes, Lazcs, and other turbulent traders, who inhabit the mountainous fastnesses, by mixing more frequently with their fellow subjects at these marts, could not fail to learn their real interest to be inseparable from the performance of their duty."

"The commerce of the Black Sea embraces, according to Reuilly, that of the Crimea, that of the shores of the sea of Azof, and those of the Abazes; that of Natolia, and of the Ottoman provinces of Asia, of Romelia, of Bulgaria, of Wallachia, and of Moldavia, and, above all, that of Poland and Russia.

"The Crimea is advantageously situated for the purposes of commerce. That peninsula, surrounded by the Black Sea, and by the Sea of Azof, in which the Don empties itself, is able to receive in its ports, principally in those of Kertch and of Caffa, the merchandises of the Indies, of Persia, and of Siberia, in the same manner as in the times of the Genoese. These merchandises, which consist in raw iron, copper, spars, pitch, skins, can come from Siberia, by following the course of the Kama and of the Volga unto Dubofka, or by crossing the isthmus 60 versts, which separate the Volga from the Don; and by being shipped at Katchalinskaya, these merchandises come down by the Don to the sea of Azof, to be carried to Taganro, or directly to Kertsh or Caffa. Butter and fat come also by this route, and with considerable profit to the traders. The sailcloth of the interior part of Russia, the hemp, the lincens, of which there are great abundance, above all in the departments of Penza, of Nishnei-Novogorod, and of Woronetz, have a short passage to make to come down by some lesser rivers to the Don.

"A depot of the merchandises which Natolia draws at present from the caravans of Smyrna, and by Constantinople, might be more advantageously situated in the Crimea, if a privilege to remove it could be obtained from the court of Russia, or if a free port were permanently established. In taking by this mart the silks of Brouse and of Persia, it would turn to the account of Russia herself. It is to be remarked, that the drugs

which came from the confines of Persia, instead of being sent into Russia by Tiflis, and from thence to their destination, are embarked at the Persian Gulf, and afterwards return by the Baltic, after having made, as one may say, the tour of the world."

Under the present article, the Editor expected to have been able to communicate some new and interesting information respecting the commerce and antiquities of the Black Sea, from his friend Colonel Leon Waxell of St Petersburg; but particular circumstances have prevented him from availing himself of the assistance of that able antiquarian, who travelled into the countries upon its shores in 1797 and 1798. In the mean time, this defect may be supplied by consulting his learned work, entitled, *Recueil de quelques antiquités trouvées sur les bords de la Mer Noire appartenans à l'empire de Russie, dessinées après les originaux en 1797 et 1798, par Leon de Waxell, Conseiller de Cour au service de S. M. J. de toutes les Russies, et Correspondant de l'Académie*; Berlin, 1803. See also Herodotus, *Melp.* 4, 85, 86. *Strabo*, lib. i. Barbié du Bocage *Analyse de la Carte des marches et de l'empire d'Alexandre*, p. 801. Olivier's *Voyage*, &c. tom. i. p. 69, and Atlas, plate ii. BLACKBURN, a town of England in Lancashire, situated upon the river Derwent, in a valley encircled with hills, and deriving its name from the blackness of the water in the Derwent. The town consists of several streets, and contains no remarkable buildings, except four stone bridges over the river. A very considerable trade is carried on here, in cotton, calicoes, and muslin, and in a kind of stuff called Blackburn gray, which is linen shot with cotton. Blackburn now communicates by canals with the rivers Dee, Mersey, Ribble, Ouse, Trent, Severn, Humber, Thames, and Avon; and, from this circumstance, its trade has considerably increased. Coal and alum are found in the neighbourhood. Number of houses, in 1801, 2332. Population 11,980; of whom 6800 were returned as employed in trade and manufactures. See Aikins' *Description of the Country from Thirty to Forty Miles round Manchester*, 4to, 1795. See also LANCASHIRE. (π)

BLACKBURNE, FRANCIS, a name which will ever be revered by the friends of religious liberty. He was born at Richmond, in Yorkshire, on the 9th of June 1705. On the banks of the river Swale, in that vicinity, his ancestors had been in possession of an estate, which his grandfather was under the necessity of selling; and, afterwards engaging in the stocking manufacture at Richmond, he was enabled to leave his son in flourishing circumstances. The latter died at an early age, and left two sons and a daughter. Francis Blackburne, the eldest of these sons, received his grammatical education at the schools of Hawkshead in Lancashire, and Sedbergh in Yorkshire. In 1722 he was admitted a pensioner of Catharine Hall, Cambridge, where he took the degree of bachelor of arts. He was afterwards elected conduct, or chaplain-fellow; and, on this title, obtained deacon's orders in 1728. It was not till

1739 that he received priest's orders, previously to his induction to the rectory of his native town. This living he obtained through the interest of Sir Congers d'Arcy, and John York, Esq. the representatives of that borough. For some time he was titular chaplain to Dr Matthew Hutton, archbishop of York; who collated him in 1750 to the archdeaconry of Cleveland, and to the prebend of Bilton. These are the only church preferments which he enjoyed; and the aggregate of his emoluments did not amount to 200*l.* per annum. From the period of his settlement at Richmond, he applied himself, with great earnestness, to his parochial duties; and he became in every respect an exemplary minister. His first appearance as an author was in 1742, when he printed an assise sermon preached at York. His strenuous defence of Christian liberty he commenced in the year 1750, by publishing *An Apology for the Authors of a Book, entitled Frece and Candid Disquisitions relating to the Church of England*. It was generally supposed, that, in the composition of that book, he had some share; but this he solemnly denied. In 1756 he engaged in the controversy respecting the intermediate state of souls. This subject had been discussed in a very learned and curious treatise of Dr Thomas Burnet; and it still occupied the attention of theologians. Mr Blackburne's earliest treatise on this topic is entitled, *No Proof in the Scriptures of an Intermediate State of Happiness or Misery between Death and the Resurrection; in answer to Mr Goddard's Sermon*. He published several other tracts on the same subject; and concluded his labours in 1765, with *A Short Historical View of the Controversy concerning the Intermediate State, deduced from the beginning of the Protestant Reformation to the present time: with a prefatory Discourse on the Use and Importance of Theological Controversy*." An edition of this work, with large additions, was published in 1772.

In these productions he displays a large fund of theological learning, and much force of reasoning; but they are not the productions which have chiefly endeared his name to an enlightened posterity. His first publication on the subject of subscription to articles of faith, is entitled, *Remarks on the Rev. Dr Powell's Sermon, in Defence of Subscriptions, preached before the University of Cambridge on the Commencement Sunday, 1757*. These remarks, which made their appearance in 1758, may be considered as preliminary to that masterly production which forms the basis of his reputation, *The Confessional; or, a Full and Free Inquiry into the Right, Utility, Edification, and Success, of establishing Systematical Confessions of Faith and Doctrine in Protestant Churches*. Lond. 1766, 8vo. This production, which, like the rest of his controversial works, appeared without the author's name, excited no ordinary degree of attention; and its publication was succeeded by that of a multitude of polemical tracts. No satisfactory answer, however, has yet been produced; and, we may venture to affirm, that his fundamental principles are such as nothing but mere prejudice or sophistry will ever attempt to explode. Blackburne repelled some of the attacks which were made on his truly liberal and excellent performance. In 1770, he published a third edition, with corrections and large additions. This work, in its state of final improvement, we earnestly recommend to the serious consideration of every man of learning and sincerity.

It was natural to suppose, that, in his connection with a church which spreads so many snares for the consciences of its ministers, the author of *The Confessional*

might experience some secret uneasiness; and, in consequence of such an impression, and of the archdeacon's high character, some leading members of the dissenting congregation in the Old Jewry, London, authorised one of his friends, on the death of Dr Chandler in 1766, to ascertain whether he was inclined to accept the situation of pastor to that society. This invitation, i. e. however, declined, for reasons which have not been made public, but which appeared satisfactory to the applicants. Although he disapproved of some of the forms and doctrines of the established church, yet he is said to have preferred it on the whole to any other religious society; and, as his attack had been chiefly directed against its injunction of subscription to articles of faith, expressed in unscriptural language, he might think his consistency sufficiently maintained, by a refusal of any further preferment which required a renewal of subscription. In this honourable resolution he steadily persevered, when, in the year 1763, the living of Middleton-Fyas near Richmond became vacant, and the Lord Chancellor Northampton was ready to bestow it upon him, in consequence of a promise which had been obtained by some of his friends. This living was tenable with his other preferments, and in value exceeded them all.

In 1768, Archdeacon Blackburne published *Considerations on the present State of the Controversy between the Protestants and Papists of Great Britain and Ireland, particularly on the question, how far the latter are entitled to toleration on Protestant principles*." His zeal against Popery manifests itself in most of the works which he produced; and it is certainly to be regretted, that, with all his benevolence and liberality, he should have been too much disposed to assimilate the Catholics of his own with those of a very different age. It is, however, to be remarked, that Blackburne resided in a part of the country where they were numerous and powerful; and that he had witnessed some imprudent displays of their spirit, at a time when their hopes were animated by the first events of the rebellion in 1745.

Blackburne published many other tracts on theological subjects; and, as he was always distinguished for the faithful discharge of his clerical duties, his life must have been spent in complete activity. For the first twenty years of his ministry, he composed a new discourse whenever he officiated. His archdeaconal visitations he endeavoured to render as useful as possible, by plain and serious charges, delivered with dignified earnestness; and his annual appearance generally attracted a large and respectable auditory. In the year 1767, he accepted the office of commissioner to the commissary of the archdeaconry; by virtue of which he presided in the spiritual court at Richmond. By his integrity and knowledge, he restored to this court a respectability not always attached to the ecclesiastical jurisdiction of his country; and his merits were very handsomely recognized by Mr Eden, now Lord Auckland, on his appointment to the commissariat. As the ecclesiastical law had not previously formed a part of his study, it has been mentioned as a proof of the vigour of his understanding, that he should make such proficiency in it as to pronounce decisions which were seldom, if ever, reversed, on appeals to a higher court.

At an advanced period of life, he formed the plan of writing copious memoirs of Martin Luther; but when he had proceeded so far as to collect a considerable mass of materials, he relinquished his undertaking in order to commemorate the patriotism and philanthropy of

a deceased friend. On the death of Thomas Hollis, he was induced by Mr Brand Hollis, the friend and heir of that gentleman, to compile an account of his life. The *Memoirs of Thomas Hollis, Esq.*, which were printed at London in 4to, in the year 1780, are usually bound in two volumes, but have only one series of pages. The book was not originally published; but, after the death of Mr Brand Hollis, some copies have come into the market, and are sold at a high price. Thomas Hollis was an English gentleman of considerable fortune, somewhat eccentric perhaps in his character, but distinguished by an ardent spirit of philanthropy. He did not himself aspire to the fame of authorship; but he was liberally anxious to promote every literary scheme of a laudable tendency; and, in particular, he expended considerable sums in reprinting some of the earlier English writers on politics. Blackburne's *Memoirs of his Life* form a very curious and entertaining production; and every page breathes the manly and liberal spirit of a genuine Whig. A portion of this work was published in a separate form, under the title of *Remarks on Johnson's Life of Milton*. Lond. 1780, small 8vo.

Blackburne was equally attached to the principles of civil and of religious freedom. He wrote several short pieces in favour of political liberty, which were inserted in the public prints; and was a large contributor to a collection of letters and essays on this subject, published in 1774, in 3 vols. 8vo. He also appears as a correspondent in the excellent Mr Wyvill's *Political Papers*, vol. iii. p. 133.

When we recollect that the memoirs of Mr Hollis were finished in the 75th year of the author's age, the vigour of his mind will not fail to excite some degree of surprise; but the death of his second son Thomas, a physician of rising eminence in the city of Durham, affected him so severely as to relax his ardour for all literary pursuits. His sight soon afterwards began to fail, and he was obliged to employ an amanuensis. The increasing infirmities of age did not, however, prevent him from performing the duties of his profession; and it was on a visitation circuit that he was seized with his last illness. He died at the parsonage house of Richmond on the 7th of August 1787, after he had completed the 82d year of his age. "Mr Blackburne," says Dr Aikin, "was of an athletic make, and by constant temperance preserved great firmness of mind and body to the very last. His recluse mode of life gave him the appearance of much austerity; but, with the few friends with whom he associated, he was cheerful and unreserved. In mixed conversation he never introduced his own speculative opinions, and experience had made him wary of answering any interrogatories on the subject." The same respectable author remarks, that his theological opinions did not so far deviate from those of the church of England, as to throw him into the class of Socinians or Unitarians. He declared himself in confidence to be a moderate Calvinist; and such a declaration might indeed have been anticipated from various passages in his writings. Some time before his death, he explicitly asserted to his relation, the Rev. Mr Comber, his belief in the divinity of Christ. It has been considered as a testimony of his general esteem for the established church, that he educated one of his sons for the clerical office.

The works of Blackburne are generally of an excellent tendency, and are always distinguished by their

intelligence and vivacity. Few writers have discussed topics of theological controversy with equal decency and animation, and in a manner so entertaining to the general reader. See Dr Aikin's *General Biography*, vol. ii. p. 173. (c)

BLACKBURNIA, a genus of plants of the class Tetrandria and order Monogynia. See BOTANY. (w)

BLACKLOCK, the Rev. THOMAS, D.D. a poet and a minister of the established church of Scotland. He was born in the year 1721, at Annan, in the county of Dumfries, but was soon afterwards removed to the town of Dumfries, where he spent the greater part of his early years. Before he was six months old he lost his eye-sight in the small-pox. This misfortune, which threatened to render him incapable of useful exertion, and leave him a burden to his family, seems to have been really the foundation of his future eminence. Endowed by nature with a lively fancy and a retentive memory, and shut out from that intercourse with the external world which sight would have afforded him, his active mind was compelled to seek employment in the exercise of its own powers. In this he was assisted by the indulgent care of his father, an intelligent tradesman, who fostered the inclination he early showed for books, by reading for his amusement whenever the intervals of business would permit, and by directing his taste to the best authors that lay within his reach. Though in his early years his father's limited circumstances did not permit him to enjoy the advantage of being educated at a grammar school, yet, by the assistance of his companions, whom the gentleness of his dispositions had warmly attached to him, he acquired some knowledge of the Latin tongue. The information thus obtained, the very circumstance of his blindness gave him an opportunity to impress more forcibly on his mind, by depriving him of the common means of relaxation. This may in some measure account for the remarkable progress which with such slender opportunities he made in his studies. Even at the early age of twelve, his poetical attempts, one of which is preserved in his poems, gave the promise of future excellence; and from that period he found in the cultivation of the muses, a delightful employment for the powers of his mind, and a protection from that *tedium*, to which the situation of the blind, when endued with sensibility, peculiarly subjects them. Before he had reached his twentieth year, he was fortunate enough to acquire a new and advantageous connection, by the marriage of his sister. This young woman, who possessed from nature, together with a very lovely person and attractive manners, all the innocent simplicity and gentleness of heart which characterised her domestic circle, had received from paternal indulgence an education superior to her station, and had begun to contribute her share to the support of the family expenses by her skill in needlework, when she became known to Mr M-Murdo, the son of a distinguished clergyman in that neighbourhood. This gentleman, who had a short time before successfully commenced business as a brewer in Dumfries, and who joined to the most fascinating manners an enlightened and accomplished mind, having, on a further acquaintance, discovered that Miss Blacklock's virtues were not inferior to her personal charms, made her his wife, and thus opened to young Blacklock an intercourse with a more polished society than he had hitherto been accustomed to. An event in itself so fortunate, was rendered still more opportune by the shock which he

was destined a short time afterwards to receive from the sudden and accidental death of his father. A fire having broken out in Mr M'Murdo's brewery, the good old man fell a victim to the boldness of his efforts in saving his son-in-law's property, and perished in the midst of the flames. This melancholy occurrence Blacklock pathetically laments in a poem written soon afterwards, which is strongly descriptive of the state of his feelings, and places his character in a very interesting point of view. It is entitled, *A Soliloquy*, and was occasioned by the following circumstance: During his father's life, the affectionate attentions of parental love had not suffered him to go out of doors without a guide, and by an amiable but injudicious tenderness had fostered his natural timidity, leaving him constantly dependant on the good offices of others for the power of moving even to a trilling distance. The death of his father, however, subjected him to many privations; and he now found it necessary to make exertions to which he had formerly been unaccustomed. When he, at any time was induced to go from home alone, he had a favourite dog, which was his constant companion, and served to alleviate the forlorn and solitary feeling which his present condition inspired. Having one day wandered from the door, he lost his way, and was on the point of stepping into a draw-well of considerable depth, covered carelessly with rotten boards, where he must have been irrecoverably lost, had not his little attendant, by the sound of its feet on the cover, warned him of his danger. This accident forcibly called to his mind all the miseries of his helpless situation, and gave rise to a production, which, for pathos, tenderness, and sublimity, rivals the most happy efforts of the British muse. The piety and resignation to the will of heaven so beautifully expressed in the concluding part of this poem, and which formed a striking trait in his character, did not pass unrewarded. He remained with his mother for about a year after his father's death, and began to be distinguished, even beyond the circle of his own immediate friends and acquaintances, as a young man of uncommon parts and genius. At the end of this period, Dr Stevenson, an eminent physician in Edinburgh, being accidentally at Dumfries, became acquainted with young Blacklock's talents, and formed the benevolent design of giving to his natural abilities the advantage of a liberal education. Under this respectable patron, he commenced his studies at the grammar school of Edinburgh in the year 1741, where he continued till the breaking out of the rebellion in 1745. During this period, he was introduced to Mr Alexander, the lord provost of the city, a gentleman who was connected with Mr M'Murdo in some commercial speculations. In this family he had an opportunity of making himself master of the French language, which was the vernacular tongue of Mrs Alexander. Before leaving the metropolis, he became an author, by publishing a volume of poems in octavo. Soon afterwards he retired to Dumfries, where he resided during the national disturbances of that period in the house of his brother-in-law Mr M'Murdo. Dumfries was at this period fortunate in being the residence of several enlightened and ingenious men, in whose society Blacklock had an opportunity of tasting the charms of friendship, of improving his acquaintance with the world, and of considerably increasing the store of his ideas. Amongst these, besides the circle of this amiable family, in which he was an inmate, it may be proper to mention Mr Jameson, the

episcopal clergyman, a worthy and ingenious man, with whom he contracted an intimate friendship; collector Gordon of Halbeths, himself a poet, who afterwards wrote an account of his life; and Mr Carlyle of Drungans, a gentleman who was bred to the law, but whose acquirements extended far beyond the limits of his profession. On the restoration of public tranquillity, Blacklock returned to the metropolis, where he continued his studies for six years longer. In the year 1754, a second edition of his poems in octavo was published at Edinburgh, and two years afterwards, a quarto edition came out by subscription in London. In the publication of the London edition, the celebrated David Hume, and Mr Spence, professor of poetry at Oxford, took a warm and active interest. This latter gentleman prefixed to that edition a very elaborate and ingenious account of Blacklock's life, character, and writings, which he had published separately two years before.

After going through the usual course of studies at the university with more than common success, he was in the year 1759 licensed by the presbytery of Dumfries to preach the gospel, and in this capacity soon obtained a high reputation. In 1762, he married Miss Sarah Johnston, daughter of an eminent surgeon in Dumfries: a connection which Providence seems to have intended as the solace and blessing of his future life. A few days after this event, he was ordained minister at Kirkcudbright, in consequence of a crown presentation obtained for him by the earl of Selkirk, a benevolent nobleman, who took an interest in his welfare. Besides the natural prejudices of the people against a pastor deprived of sight, there were some other circumstances which combined to render his ordination unpopular amongst the inhabitants of the parish. At that period the disputes concerning patronage ran high throughout the kingdom; and the aversion of the lower classes to the exercise of that right, frequently, as in the present instance, prejudiced them against the presentee. Besides, it was known that the living had been bestowed on Blacklock through the interest of lord Selkirk, with whom the town's people were at that period unfortunately involved in some political animosities, which made them look on his interference with a jealous eye. Add to all this, that the poet's language and style of preaching, though in themselves extremely good, and well adapted to the taste of an enlightened congregation, were too refined and philosophical to be relished, or perhaps understood, by that description of people of which his hearers were chiefly composed. It will not appear surprising, therefore, that much dissatisfaction should have prevailed at his nomination to that living; and those who are acquainted with the habits and feelings of the Scottish peasantry, will easily conceive the violent lengths to which such a combination of irritating circumstances would naturally lead them. The fact is, that he entered the town amidst the hisses and hootings of the populace; that his passage to the church, where the ceremony of ordination was to be performed, was obstructed; and that it was not without imminent danger to the persons of himself and his friends, that a way was made for him through the enraged crowd. The lively sensibility of Blacklock's mind was deeply wounded by this undeserved hostility, and the scenes of happiness which his benevolent heart and ardent imagination had pictured to him in the discharge of his clerical duties, vanished from his view. Instead of finding himself, as he had fondly hoped, installed in an office, every

duty of which was to be a labour of love, he saw nothing before him but unavailing wishes, thankless toils, and endless contentions. After dining with some friends who had accompanied him from Dumfries, finding rest necessary to recruit his harassed and exhausted spirits, he left the table and retired to bed, when the following extraordinary circumstance occurred, which merits particular notice as a curious fact relative to the state of the mind in sleep. One of his companions, uneasy at his absence from the company, went into his bed-room a few hours afterwards, and, finding him, as he supposed, awake, prevailed upon him to return into the dining room. When he entered the room, two of his acquaintances were engaged in singing, and he joined in the concert, modulating his voice as usual with taste and elegance, without missing a note or a syllable; and after the words of the song were ended, he continued to sing, adding an *extempore* verse, which appeared to the company full of beauty, and quite in the spirit of the original. He then went to supper, and drank a glass or two of wine. His friends, however, observed him to be occasionally absent and inattentive. By and by he was heard speaking to himself, but in so slow and confused a manner as to be unintelligible. At last, being pretty forcibly roused by Mrs. Blacklock, who began to be alarmed for his intellects, he awoke with a sudden start, unconscious of all that had happened, having been the whole time fast asleep. The principal part of these remarkable particulars, is mentioned by Dr Cleghorn in his *Thesis De Somno*. Where the writer of this article has ventured to make some additions to that account, he is supported by the testimony of Mrs Blacklock, from whom he personally obtained the anecdote.

Blacklock finding his situation in Kirkeudbright exceedingly irksome and painful, resigned his right to the living after a legal dispute of two years, and accepted of a moderate annuity in its stead. With this slender provision, he removed in 1764 to Edinburgh, where he adopted the plan of receiving a certain number of young gentlemen into his house as boarders. In this situation he continued with much success for 23 years, directing the studies of his boarders with the most affectionate care, and improving their minds by his enlightened conversation. "In the occupation which he thus exercised for so many years of his life," says the author of the *Man of Feeling*, in the elegant memoir he has prefixed to the posthumous edition of his poems, "no teacher was perhaps ever more agreeable to his pupils, nor master of a family to its inmates, than Blacklock. The gentleness of his manners, the benignity of his disposition, and that warm interest in the happiness of others, which led him so constantly to promote it, were qualities which could not fail to procure him the love and regard of the young people committed to his charge; while the society, which esteem and respect for his character and his genius often assembled at his house, afforded them an advantage rarely to be found in establishments of a similar kind." The writer of this account has frequently been a witness of the family scene at Dr Blacklock's; has seen the good man amidst the circle of his young friends, eager to do him all the little offices of kindness which he seemed so much to merit and to feel. In this society he seemed entirely to forget the privation of sight, and the melancholy which at other times it might produce. He entered with the cheerful playfulness of a young man into all the sprightly narrative, the sportful fancy, the humorous jest, that

rose around him. It was a sight highly gratifying to philanthropy, to see how much a mind endowed with knowledge, kindled by genius, and above all, ligated up with innocence and piety, like Blacklock's, could overcome the weight of its own calamity, and enjoy the content, the happiness, and the gaiety of others. Several of those inmates of Dr Blacklock's house, retained in future life all the warmth of that impression which his friendship at this early period had made upon them; and in various quarters of the world he had friends and correspondents, from whom no length of time, and no distance of place, had ever estranged him.

In 1766, upon the unsolicited recommendation of his friend Dr Beattie, the degree of doctor of divinity was conferred on him by the university of Aberdeen.

In 1787, finding that his time of life, and the state of his health, required repose, he was induced to discontinue the receiving of boarders. In the mean time, the infirmities of age were rapidly and visibly advancing. A constitutional lowness of spirits, to which, even in the vigour of youth, the delicate sensibility of his nerves had at times rendered him subject, began to recur more frequently, and with greater severity; and a general indisposition both of body and mind, indicated the near approach of that period beyond which protracted life is often little more than protracted pain. Amidst these indispositions of body, however, and disquietudes of mind, the gentleness of his temper never forsook him, and he felt all that resignation to the will of the Supreme Being, and confidence in his goodness, which, through every vicissitude of life, had habitually supported his mind. In summer 1791, he was seized with a feverish disorder, which on the 7th July, after about a week's illness, ended in his death.

The character of Blacklock, whether we consider the qualities of his heart, or the endowments of his understanding, is worthy of admiration. To an eager sensibility and quickness of feeling, which is the peculiar temperament of poetic genius, he joined an uncommon gentleness and candour of mind. His vigorous understanding, and his ardent pursuit of knowledge, were chastened and adorned by an amiable modesty, and an innocent simplicity of manners. Deprived of sight in early infancy, nature seems to have compensated for this misfortune, by opening to him many sources of enjoyment unknown to common minds. As he was debarred from those amusements and avocations which distract and embarrass the mental powers, he devoted himself to learning, and successfully cultivated the elegant pleasures of taste and fancy. Amidst disadvantages and discouragements which would have overwhelmed a more feeble mind, he was distinguished by his proficiency in classical literature, in belles lettres, in metaphysics, and in all the various branches of knowledge for which the age is distinguished. As a poet, his merit has been long known and acknowledged. The productions of his muse are marked with such an elegance of diction, such an ardour of sentiment, and such a glow and propriety of description, as must excite the approbation, and affect the feelings, of every reader of taste. What is particularly remarkable in the works of one deprived from his earliest infancy of the blessing of sight, is the accurate and beautiful descriptions of visible objects with which his writings abound. This circumstance has raised the astonishment of all who are capable of forming an opinion on the subject. Mr Spence, his elegant panegyrist, has treated this descriptive power

in one labouring under such a deprivation, as a sort of problem, which, in a very ingenious but fanciful manner, he has endeavoured to explain. Professor Denina, an ingenious foreigner, in his *Discorso della Letteratura*, has expressed himself on this subject in terms of admiration and surprise. "Blacklock," says he, "to posterity, will seem a fable; as to the present age, he is a prodigy. It will be thought a fiction, that a man blind from his infancy, besides having acquired a surprising knowledge of Greek, Latin, Italian, and French, should at the same time be a great poet; and, without having almost ever seen the light, should, notwithstanding, be singularly happy in his descriptions." Though we may not be inclined to subscribe to the theory which Mr Spence has adopted, or to ascribe to Blacklock any extraordinary or supernatural conception of visible objects, we may at least fairly claim for him a singular felicity of combination in his use of the expressions by which these objects are distinguished. A retentive memory, and an intimate acquaintance with poetical language, joined to an enthusiastic and creative fancy, which embodied all his ideas, may perhaps go far to account for a phenomenon which has exercised the talents of ingenious men both at home and abroad. With respect to the other qualifications of Blacklock as a poet, we do not hesitate to say, that he exhibits proofs of an ardent imagination, a refined taste, and a feeling heart. "One other praise," says Mr M'Kenzie, with no less truth than elegance, "which the good will value, belongs to those poems in a high degree,—they breathe the purest spirit of piety, virtue, and benevolence. These indeed are the muses of Blacklock; they inspire his poetry, as they animated his life; and he never approaches the sacred ground on which they dwell, without an expansion of mind and an elevation of language."

Besides the publications already mentioned, Blacklock was the author of several other works, which add to his fame as a poet the character of a profound philosopher and skilful theologian. In 1756, he published at Edinburgh, *An Essay towards Universal Etymology, or the Analysis of a Sentence*, 8vo. In 1760, he published, *The Right Improvement of Time*, a sermon, 8vo; and in the same year, he contributed several poetical pieces to the first volume of Donaldson's *Collection of Original Poems by Scots Gentlemen*, 12mo. In 1761, he published, *Faith, Hope, and Charity compared*, a sermon, 8vo. In 1767, he gave to the world his *Paraclesis; or Consolations deduced from Natural and Revealed Religion, in two Dissertations. The first supposed to have been written by Cicero, now rendered into English, the last originally composed by Thomas Blacklock, D. D.* In 1768, he published without his name, *Two Discourses on the Spirit and Evidences of Christianity, translated from the French of the Reverend James Armand, Minister of the Wuloon Church in Hanau*. In 1773, he published a poem, entitled, *A Panegyric on Great Britain*, 8vo. In 1774, he published *The Graham, an Heroic Ballad*, in four cantos, 4to. In 1793, a posthumous edition of his poems was published by Mr M'Kenzie. There are still unpublished some volumes of sermons in manuscript, together with a treatise on morals, both of which his friends have had it in contemplation to give to the world. See an account of Blacklock's life by Mr Gordon, prefixed to the edition of his poems published at Edinburgh in 1754; another by Mr Spence, prefixed to the edition of his poems published at London in 1756; another by Mr M'Kenzie, prefixed to the posthumous edition of his

poems in 1793; and another by Dr Anderson, in his *Lives of the Poets*. (H. D.)

BLACKMORE, SIR RICHARD, was the son of Mr Robert Blackmore, attorney at law, and was born at Corsham, in Wiltshire, about the year 1650. He received the first elements of education in a country school; removed to Westminster in the 13th year of his age; and was sent to the university of Oxford in 1668, where he resided twelve or thirteen years without much apparent improvement in literary acquisitions. It is supposed, that, after leaving the university, he was engaged a short time in the profession of a schoolmaster; but it is better ascertained, that he travelled into Italy, and took the degree of doctor of medicine at the university of Padua. Having spent about a year and a half on the continent, during which period he visited France, Germany, and the Low Countries, he returned to London, where he commenced the practice of physic, and was chosen fellow of the Royal College of Physicians in 1687. His growing reputation in his profession, and his decided attachment to the principles of the revolution, recommended him so strongly to the notice of king William, that, in 1697, he was chosen one of his majesty's physicians in ordinary, and received, about the same time, the honour of knighthood, accompanied with the gift of a gold chain and medal. A few years before this exaltation, he had commenced his literary career, by the publication of *Prince Arthur*, a heroic poem, which was so favourably received, that it passed through three editions in the space of two years. He published, in 1697, a similar poem, entitled, *King Arthur*; in 1700, *A Paraphrase on the book of Job*; and, in the same year, a poem entitled, *A Satire upon Wit*, which was intended as a censure upon the licentious tendency of many of the productions in his time; in 1705, another heroic poem, entitled, *Eliza*; in 1712, a philosophical poem, the best of his productions, entitled, *Creation*; in 1714, a volume under the title of *The Lay Monastery*, consisting of forty numbers, which had appeared periodically in the preceding year; in 1716, *Essays upon several Subjects*, 2 vols. 8vo.; in 1718, *A Collection of Poems*, in one volume, 8vo.; in 1721, *The Redeemer*, a poem; in the same year, *A new Version of the Psalms of David*, which was recommended, by an order of council, as proper to be used in the churches and chapels of England; and a variety of other pieces, partly theological, but chiefly on medical subjects, such as the plague, small-pox, consumption, spleen, gout, rheumatism, king's evil, dropsy, tympany, jaundice, stone, and diabetes. He died on the 8th of October 1729, and manifested the most elevated piety during his last illness.

Few authors have been more severely satirised than Sir Richard Blackmore; and his name has been too readily associated, upon the authority of his enemies, with the essence of absurdity and dulness. He must be admitted, indeed, to have been justly obnoxious to ridicule, on account of his tedious historical epic poems; to have written too hastily and carelessly; to have been extremely negligent in correcting and polishing his compositions; and to have, in many instances, discovered extraordinary deficiency in point of true taste; but he was far from deserving that extreme contempt with which he has been treated, and was by no means destitute of ability, learning, or even of poetical genius. Some of his keenest opponents have acknowledged, that his poems possess a certain degree of merit, and de-

serve a considerable portion of applause; and many eminent literary characters, Mr Duncombe, Mr Addison, Mr Locke, Mr Molyneux, and Dr Watts, have spoken of his works, especially of his poem on *Creation*, in terms of high approbation. There is too good reason to believe, that it was his religion more than his dulness which excited much of the animosity which he sustained, and that he incurred such bitter attacks from his contemporaries chiefly by his censures of their immorality and profaneness. But, whatever becomes of his fame as an author, there can be no dispute on the subject of his personal character. He was always a most zealous advocate for the interests of religion and virtue; was distinguished by the fervent piety and moral excellency of his own life; and, while his numerous enemies were unable to attach the slightest moral stain to his memory, his acquaintances and friends have highly extolled his private virtues. See *Biog. Britan. Gen. Biog.* Johnson's *Lives of the Poets. Spectator*, No. 339. Watt's *Hero Lyrica, Preface.* Locke's *Works*, vol. iii. p. 568. Duncombe's *Coll. of Letters*, vol. i. p. 121, &c. (y)

BLACKSTONE, SIR WILLIAM, an English lawyer of great celebrity, was born at London on the 10th of July 1723. He was the third son of Charles Blackstone, a silk mercer; but, being left an orphan, the charge of his education was generously undertaken by his maternal uncle, Thomas Biggs, a surgeon in London. At an early age he was sent to the Charter-house school, and was some years afterwards admitted a scholar on the foundation. In November, 1738, he was entered at Pembroke College, Oxford. At both these seminaries he distinguished himself by his proficiency in classical learning. His attainments do not, however, seem to have been circumscribed by the ordinary limits of academical discipline: At the age of twenty, he composed, for his own use, an elementary treatise on architecture, which was never published, but which is said to possess great merit. Having determined to embrace the profession of the law, he entered himself of the Middle Temple; and, in 1744, he quitted Oxford, and those classical pursuits which were so congenial to his taste. This transition to studies of a less pleasing nature, he very feelingly commemorated in an elegant poem, entitled, *The Lawyer's Farewell to his Muse*, which was afterwards printed in the 4th volume of Dodsley's collection, and which is allowed to display a very early maturity of taste and judgment. He now applied himself with great assiduity to the studies of his profession; dividing his residence between the Temple and the university, a place to which he always retained his youthful attachment. He had been elected a fellow of All-souls College in 1743; and, on the 28th of November 1746, he was called to the bar. As he was very deficient in elocution, and possessed none of the popular talents of an advocate, his progress in the profession was extremely slow; and, being without any avocations of business, the active turn of his mind displayed itself in the office of bursar, or steward, of All-souls. In this situation he is said to have merited great praise for his skill and diligence in arranging the records and improving the revenues of the college, and in expediting the necessary measures for completing the magnificent structure of the Codrington library. In 1749, he was appointed, through the interest of a relation, recorder of Wallingford in Berkshire; and, in the following year, probably with a view to more constant residence at Oxford, he took the degree of doctor of laws.

After Blackstone had attended the courts at Westminster for a period of seven years, his prospect of success was so extremely precarious, that he determined to quit the regular practice of his profession, and retire to his fellowship. To this determination he was indebted for the future distinctions of his life. "The system of education in the English universities," says a very intelligent biographer, "having been established in remote ages, and intended solely for the instruction of the Popish clergy, was without any public provision for teaching the laws and constitution of their own country; and from that mixture of pride and indolence, which is the characteristic of ancient and wealthy establishments, the defect was suffered to continue after the universities had ceased to be appropriated to ecclesiastics, and had become places of general education. This defect Mr Blackstone now undertook to supply by a course of public lectures on that important subject; and the manner in which he executed the task, has conferred great and lasting distinction on the university in which his lectures were delivered. It is indeed a singular circumstance, and may be of some use in enabling us to appreciate the merit of our academical establishments, that, in the long succession of public teachers and professors, during a period of several centuries, the Commentaries of Blackstone, and the Hebrew Prelections of Lowth, are the only series of lectures in either university which have any prospect of descending to posterity, or of acquiring a permanent place in the literature of their country."

Blackstone commenced his first course of lectures in Michaelmas term 1753; and they continued to be repeated, during a series of years, with great and increasing reputation. It was probably the success of this attempt, that suggested to Mr Viner the plan of endowing, by his will, a liberal establishment in the university of Oxford for the study of the municipal law. In October 1758, Dr Blackstone was unanimously elected the first Vinerian professor; and, on the 25th of the same month, he delivered his introductory lecture before the heads of the university. This judicious discourse, which he soon afterwards published, is now prefixed to his Commentaries. His employment, as a public lecturer, did not prevent him from occasionally exercising his profession as a provincial barrister. The famous Professor Millar of Glasgow sometimes followed the same practice.

The reputation which he had acquired by his lectures, induced him, in the year 1759, to return to the Temple, and resume his attendance at Westminster-hall; and he now advanced with great rapidity in the career of his profession. Though he never attained to the very first rank in business, yet it appears from the books of reports, that, during a considerable period, there were few cases requiring great learning and research in which he was not employed. In 1761, he was chosen member of parliament for Hindon; and received a patent of procedure to rank as king's counsel, having previously declined the office of chief justice of Ireland. On the establishment of the queen's household, in 1763, he was appointed solicitor-general to her majesty.

In May, 1761, he married Sarah, the eldest daughter of James Clitherow, Esq. of Boston-house, in the county of Middlesex. Having vacated his fellowship by marriage, he was immediately afterwards appointed principal of New-Inn Hall, by the Earl of Westmoreland,

at that time chancellor of the university. This office, as well as the Vinerian professorship, he resigned in the year 1766.

It was about this period of his life that he laid the foundation of his fame as an author. Some years before the appearance of his great work, he collected several smaller productions, which had been printed in a separate form, and republished them under the general title of *Law Tracts*. Oxford, 1762, 2 vols. 8vo. The first volume contains, *An Essay on Collateral Consanguinity, Considerations on Copyholders, and A Treatise on the Law of Descents*. The second contains, *The Great Charter and Charter of the Forest, with other Authentic Instruments: to which is prefixed an Introductory Discourse, containing the History of the Charters*. This historical introduction is of considerable length, and displays a familiar acquaintance with the study of antiquities. The original publication of his edition of the great charter implicated him in a controversy with Dr Littleton, then Dean of Carlisle. In the year 1759, Blackstone had published two small tracts of a local and temporary nature, which he has excluded from this collection. The one is entitled, *Reflections on the Opinions of Messieurs Pratt, Moreton, and Wilbraham, relating to Lord Litchfield's Disqualifications* for the chancellorship of the university; the other, *A Case for the Opinion of Council, on the Power of the University to make New Statutes*.

The first volume of his *Commentaries on the Laws of England*, was published at Oxford, in 4to, in the year 1765; and the other three volumes followed soon afterwards. This work, to which he is indebted for the permanence of his reputation, comprehends the substance of his academical prelections; and is by far the most elegant and popular book on the municipal laws of England which has yet appeared. Before the publication of Blackstone's *Commentaries*, the study was generally considered as extremely repulsive; but he has treated it with a degree of elegance and interest, which may recommend it to every inquisitive reader. His arrangement, if not perfectly unexceptionable, is at least sufficiently perspicuous; and the work is even valuable on account of its genuine English style. This production, though of the elementary kind, is by no means superficial: with his accuracy and judgment he has united a very industrious spirit of research. But, with all these merits, it exhibits some radical defects, against which it is highly expedient to caution the young and ingenious student. It is remarked, by the very judicious writer of his life in the *General Biography*, "that Blackstone, in those parts of his *Commentaries* where he examines the reasons and principles of law, discovers no portion of the philosophical spirit; and that he does not rise above the ordinary level of those writers, who, in every age and country, have extolled their own municipal institutions as the 'wisdom of ages,' and the 'perfection of reason.' In discussing the propriety of particular laws, his ingenuity is always occupied by the *forms* of jurisprudence; and, instead of referring to public convenience and general utility, the sole standard of all rational legislation, he perpetually appeals to those technical arguments which are dignified with the title of 'legal reasons.' He is in all cases the advocate and the apologist of existing institutions; and it is the constant tendency of his work to justify whatever has been established by antiquity, to discredit the improvements of modern times, and to expose to contempt, or indig-

nation, all proposals for further change. He is one of that servile class of writers, under whose auspices the mind of a nation makes no advances, who confirm the prejudices and ignorance of the people, while they flatter the pride and indolence of government. In his political principles, he is the slave of power and the advocate of prerogative; and his ecclesiastical opinions are strongly tinged with the spirit of religious bigotry and intolerance. It deserves to be remarked, that, notwithstanding this deference to authority, the *Commentaries* of Blackstone contain several very strong passages against standing military establishments, and the policy of keeping soldiers apart from their fellow-citizens in barracks or fortifications; nor has any political writer delineated in stronger terms the progress of the influence of the crown, or the probable effects of a further increase of the national debt. This circumstance, which appears at first so singular, must be attributed to the spirit of the times, rather than to that of the writer. So natural and obvious did the introduction of those topics *then* appear in a work on the British constitution, that they could not, with propriety, be omitted by the most determined supporters of prerogative."

Soon after the publication of this work, Blackstone was involved in a controversy with Dr Furneaux and Dr Priestley; who attacked the ecclesiastical parts of it with great ability, and, we may add, with great success; for, if their chastisement did not extort a candid acknowledgment of his errors, it at least produced a silent retrenchment, in the subsequent editions, of the more obnoxious passages. His political principles were still more severely exposed, in an acute production, entitled *A Fragment on Government, written by Jeremy Bentham, Esq.* It has been mentioned, to the honour of Blackstone, that notwithstanding the severity of this criticism, he, some years afterwards, became acquainted with the author, and lived with him on terms of friendship and regard.

He was likewise involved in a controversy respecting the famous case of the Middlesex election. In the House of Commons he gave it as his opinion, that an expelled member was not eligible to the same parliament; and this doctrine appearing to contradict the language of his *Commentaries*, he was keenly exposed for his inconsistency by the celebrated Junius, and by other writers of inferior distinction. On this occasion he certainly defended himself with great ingenuity: but his subsequent conduct added considerable weight to the charge which had been preferred against him; for, in the next edition of his work, he inserted the case of expulsion, of which no previous notice had been taken, among the disqualifications to sit in parliament.

Blackstone's real merits, and what is generally of greater consequence, his servile devotion to the ministry, were not suffered to pass unrewarded. On the resignation of Mr Dunning in 1770, he was offered the situation of solicitor general, which naturally leads to the highest offices of the law; and, on his declining it, he was appointed one of the justices of the court of common pleas. In this honourable and tranquil station he continued till the time of his death, which happened, in consequence of a dropsy, on the 14th of February 1780. His health, which had been considerably impaired by the labours of his early years, by an unfortunate aversion from exercise, and perhaps by some habits of excess, had been declining for some time; but it

had begun seriously to fail towards the latter end of the preceding year.

The private character of Blackstone seems to have been highly estimable for mildness, benevolence, and every social and domestic virtue. A love of business, and useful employment, was one of the ruling passions of his life; and the leisure which he enjoyed during his latter years, was devoted to schemes of social improvement in the neighbourhood where he resided, or to great public undertakings. He left in manuscript, two volumes of reports, which have been published since his death, but without adding much to his reputation as a lawyer. See *Life of Blackstone*, prefixed to his *Reports*; and Aikin's *General Biography*, vol. ii. p. 177. (c)

BLACKWELL, THOMAS, was born in Aberdeen in the year 1701, and was the son of the Rev. Thomas Blackwell, one of the ministers, and principal of Marischal College in that city. He received his grammatical and university education in his native place, and took the degree of master of arts in the seventeenth year of his age. In the year 1723, he was appointed professor of Greek in the Marischal College, of which he was also made principal in the year 1748; and is the only layman who has been advanced to that office since the patronage fell to the crown, by the forfeiture of the Marischal family in 1716. He still retained his Greek class, which he continued to teach with great assiduity and success till within a few years of his death; and in 1752 he received the degree of doctor of laws. In the latter part of his life he was afflicted with a consumptive disorder which he is supposed to have greatly aggravated by his obstinate perseverance in excessive abstemiousness. It was recommended to him to travel for the benefit of his health, and, in February 1757, he set out from Aberdeen for that purpose; but he was unable to proceed farther than the city of Edinburgh, where he died in March following, in the 56th year of his age. Dr Blackwell's literary productions were, *An Inquiry into the Life and Writings of Homer*, published in 1735; a work of little method, but of great ingenuity and learning;—*A Key to the Inquiry*, published in 1736, containing a translation of the numerous Greek, Latin, Spanish, Italian, and French notes in the original work;—*Letters concerning Mythology*, published in 1748; a very miscellaneous and desultory composition, but full of erudition and fancy, and containing a variety of interesting details; *Memoirs of the Court of Augustus*, of which the first volume appeared in 1753, the second in 1755, and the third, which was posthumous and incomplete, in 1764; a book which is written with great parade of language and peculiarity of style, but which contains an immense fund of curious information. In all the productions of Dr Blackwell, there is a very considerable dash of pedantry and affectation, which gradually increased with his years; but it is a pedantry of a very peculiar description, and is an attempt at once to display the erudition of a scholar, and to write with the polite ease of a gentleman. He was well acquainted with all the ancient, and with most of the modern languages, and had also read very extensively in the departments of history and the belles lettres; but he was too much inclined to assume the appearance of universal knowledge, and frequently exposed himself by attempting discussions in philosophy and mathematics, in which his attainments were very defective. He discharged his duties as a public teacher with great diligence, and merited applause. He commanded the attention of his

students by the dignity of his address; enforced application by a steady exaction of the prescribed exercises; excited an ardour of study by his own enthusiasm for the beauties of the ancients; communicated much accurate classical learning by his perspicuous and engaging manner of teaching; diffused particularly a keener relish for Grecian erudition; and may justly be regarded as having principally contributed to the future eminence of such men as Campbell, Gerard, Reid, Beattie, Duncan, and the two Fordyces. He possessed an equable flow of spirits, an entire command of his passions, a great fund of good humour, and a considerable degree of ease and politeness in his manners. In his private life he was studious and retired, seldom entering into mixed companies, and choosing the conversation chiefly of men of learning and of superior rank to himself. He was known to several persons of eminence, and numbered among his literary correspondents the celebrated Dr Mead and Dr Warburton. See *Bug. Britan.* (g)

BLADHIA, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY. (w)

BLERIA, a genus of plants of the class Tetrandria, and order Monogynia. See BOTANY. (w)

BLAIR, HUGH, D. D. and F. R. S. E. an eminent Scottish divine, was born in Edinburgh on the 7th of April 1718. Descended from the ancient family of Blair in Ayrshire, which, at different periods, has given to the world individuals remarkable for their talents and learning, he seems to have inherited from his ancestors those abilities that entitle him to be ranked amongst the ornaments of his country. His great grandfather, Mr Robert Blair, minister of St Andrew's, and chaplain to Charles I., was a man eminent in a barbarous and bigotted age for the elegant acquirements of the scholar, and the mild and dignified virtues of the Christian. His grandfather and father were respectable merchants in Edinburgh, and both of them had the honour to fill high situations in the magistracy of that city. The latter of these, John Blair, having, in common with many of his countrymen, imprudently engaged in the South Sea scheme, had the misfortune to suffer considerably in his pecuniary circumstances, and, retiring from mercantile business, obtained an office in the excise. This event had probably a considerable influence on the character, as well as the prospects of young Blair. Being thus deprived of a paternal inheritance, he found it necessary to depend for his future maintenance on his own personal exertions; a circumstance which would serve to stimulate his industry, and to give a more determined direction to the efforts of his genius. Having early imbibed a predilection for the clerical profession, to which the fame of his ancestor Robert may perhaps have contributed, his education was conducted with a view to this object. After the usual grammatical course at school, he became, at twelve years of age, a student in the university of Edinburgh. At this seminary he spent eleven years, employed with industry and success in preparing himself for the duties of the sacred office, for which he was destined. During this period, the talents which were afterwards to render him so conspicuous were not wholly concealed. Whilst attending the logic class, then ably taught by Dr Stevenson, he composed, as an exercise, an essay on *The Beautiful*, which was received by his professor with the most flattering marks of approbation, and appointed to be read in public at the end of the session. This honourable distinction made a deep impression on his mind, and he ever after

spoke of it as the circumstance which determined the bent of his genius to the study of polite literature, and fixed in his mind at once the laudable ambition and the hope of future eminence.

The talent for accurate arrangement, which forms so conspicuous a part of Dr Blair's literary character, was about this period displayed in the formation of a plan of study which greatly contributed to facilitate his labours. He had felt the difficulty of fixing in the mind the series of useful insulated facts which may occur in the course of desultory reading, and, to assist his memory, he thought of communicating them to paper, arranged under some distinct and appropriate heads. This idea he afterwards digested and improved; and applying it particularly to the study of history, he at last constructed a very comprehensive scheme of chronological tables. This scheme has since been given to the world in a more extensive and correct form, by his learned friend Dr John Blair, prebendary of Westminster, in his excellent treatise on the *Chronology and History of the World*.

Whilst Dr Blair was thus, by his judicious and persevering exertions, improving the powers of his mind, and laying up a store of useful knowledge, he was fortunate enough to form some connections of friendship which tended to stimulate his ambition, and to call his talents into action. The university of Edinburgh contained, at that period, a bright constellation of rising genius, which was soon to illuminate and adorn this northern hemisphere, and to give to Scotland a distinguished place in the world of letters. The acknowledged abilities, and the amiable manners of the young student in theology, were sufficient to gain him the esteem of his fellow students; and amongst those whom a similarity of talents and dispositions had particularly attached to him, he could number many who afterwards made a conspicuous figure in the civil, the ecclesiastical, and the literary history of their country. The friendship of a Wedderburn, a Robertson, a Smith, and a Hume, must have contributed, in no common degree, to form his taste, and mature his judgment.

In 1739, two years before he had completed his academical studies, Dr Blair took his degree of A. M. The subject of his thesis on that occasion, was *De fundamentis et obligatione Legis Naturæ*; which gave him an opportunity of displaying the extent of his reading on this important subject, and of exhibiting that virtuous sensibility of heart, and that love of moral truth, which form so striking a feature in his character as a man, and in his instructions as a Christian teacher.

His academical course being completed, he underwent the customary trials before the presbytery of Edinburgh, and was, on the 21st October 1741, licensed by that venerable body to preach the gospel. His first appearances in the pulpit, though they exhibit some of the flowery redundances of a youthful style, were so far above mediocrity as to be heard by the well-educated audiences of the metropolis with surprise and pleasure; and one sermon, in particular, which he delivered to a crowded congregation in the West Church, procured him so much deserved applause, that the earl of Leven, unsolicited, interested himself warmly in his favour, and procured for him a presentation to the church of Collessie, in Fifeshire; of which parish he was, on the 23d of September 1742, ordained minister. In this obscure situation, however, he did not remain more than ten months. His eloquence in the pulpit, joined to the ami-

able virtues of his private life, had attached to him many friends in his native city, who eagerly watched for an opportunity of shewing their admiration of his talents; and a vacancy having occurred in the Canongate Church of Edinburgh, which was to be supplied by popular election, he was proposed as a candidate. Although his competitor in the canvas was Mr Robert Walker, a man in high estimation for his flowery and popular eloquence, who was supported by a powerful and zealous party, yet, with circumstances honourable to his character, he obtained a decided majority, and was accordingly translated to a situation where a greater field was opened to his talents. In this station he remained with a growing reputation for the period of eleven years, assiduously devoting himself to the duties of his office, and carefully attending to every circumstance which might improve his compositions, and render them more worthy of the applause they so liberally received. This laudable industry soon met with the reward which it merited. His more mature taste easily rejected the youthful ornaments with which his earlier productions were loaded, and his style, whilst it lost nothing of its original warmth and energy, assumed a polished chasteness and propriety that discovered the hand of a master. His success as a preacher, indeed, depended almost entirely on the intrinsic merit of his discourses, and owed nothing to the charm of delivery, which so wonderfully embellishes even moderate talents, and gives such a fictitious value to the sentiments of a public speaker. Though his manner was serious, his voice was weak and unmusical, and his pronunciation, which was by no means remarkable for its correctness, was marred by a *bar*, or indistinct articulation of the letter R. Notwithstanding these unfavourable circumstances, however, the superiority of his abilities was universally acknowledged, and paved the way to him for higher preferments. In 1754, he received a call from the town council of Edinburgh, and was, on the 11th October, translated from the Canongate to Lady Yester's Church in the city. Whilst he remained in this charge, the University of St Andrew's paid a very flattering tribute to his talents, by conferring on him the degree of D. D. a literary honour which was at that time of some value in Scotland. During this period, too, he found sufficient leisure, from the laborious duties of his profession, to turn part of his attention to subjects of general literature, and, in conjunction with some of the ablest men in the kingdom, to conduct for a short time a periodical work of great merit, entitled *The Edinburgh Review*. In this work Dr Blair had an opportunity of shewing the extent and accuracy of his critical *acumen*, by a review of several contemporary productions, and particularly of Dr Hutcheson's ingenious system of moral philosophy.

A farther advancement was yet in reserve for Dr Blair,—the highest and most honourable to which, in the line of his profession, a clergyman of the Church of Scotland can aspire. On the 15th June 1758, he was promoted to the High Church of Edinburgh, at the express request of the lords of council and session, and of the other distinguished characters who, from their official situation, attended divine service in that church.

Having now, by unwearied application, laid in a stock of sermons sufficient to relieve him from the weekly drudgery of preparation for the pulpit, he began to think seriously of teaching to others that art which had contributed so materially to the advancement of his own re-

putation. With this view he prepared a course of lectures on composition, and being encouraged by his friends, he, with the approbation of the university, began to read them in the college, on 11th December 1759. To this undertaking he brought all the qualifications requisite for executing it well; and, along with them, a weight of reputation which could not fail to give effect to the lessons he should teach. Accordingly his first course of lectures was received with great applause; and in the following summer, on the application of the patrons of the university, his majesty erected and endowed a professorship of rhetoric and belles lettres, and appointed Dr Blair, "in consideration of his approved qualifications, regius professor thereof, with a salary of 70*l*." These lectures, which were published when declining health induced him to retire from the labours of the office, do honour to the taste and judgment of the author.

About this period, Mr McPherson, by the persuasion and under the patronage of Dr Blair and Mr John Home, undertook a tour through the Highlands, and collected the materials of those admirable poems which bear the name of Ossian. On the publication of this literary phenomenon, the opinion of the public was much divided, both with regard to its intrinsic merit and its authenticity. Dr Blair entertained for it the partiality of a protector and guardian; and being in possession of information sufficient to convince him that it was no imposture, he determined to give to it all the sanctity of his authority. With this view, he published a dissertation on these poems, which, in beauty of language, elegance of taste, and accuracy of critical discrimination, is not unworthy of his high reputation.

Dr Blair now began to take a warm and decided, though not very public, part in the politics of the church. In this department of his clerical duty, he espoused the cause of that party to which the eminent abilities and popular eloquence of Dr Robertson had given consistency and strength, and which was distinguished at that period not less by the character than the name of moderation. The leading principle which directed all the measures of Dr Robertson and his friends, was to preserve the church, on the one side, from a slavish, corrupting dependance on the civil power; and, on the other, from a greater infusion of democratical influence than is compatible with good order, and the established constitution of the country. The Church of Scotland still smarted under the wounds inflicted upon it by the persecuting spirit of the last of the Stuart race, and, on this account, a majority of the lower orders, and many of the clergy, still cherished the spirit of their forefathers, though no longer required by the exigency of the times, and entertained an inordinate jealousy of persons in power. Against these prejudices this profound politician successfully exerted his talents, and in this laudable undertaking he was cordially supported by his colleague Dr Blair; but these excellent men do not seem to have been sufficiently aware of the insinuating nature of civil authority, and in their zeal to repress faction and turbulence, perhaps with too rash and indiscreet a hand, put the weight into the opposite scale. From diffidence, and probably from a certain inaptitude for extempore speaking, which is not unfrequently the attendant of a refined taste, Blair did not venture often to take a public part in the discussions of the church courts; and, from the same causes, he never would consent to become moderator of the general assembly of the

church of Scotland. But his influence among his brethren was extensive; his opinion had always been held in high repute by the friends with whom he acted, and, for many of the last years of his life, was received by them almost as a law.

Dr Blair's fame as a preacher had hitherto rested entirely on his appearances in the pulpit; but in the year 1777, his friends prevailed on him to favour the world with a volume of sermons. These were received with such flattering marks of public favour, that he was encouraged to proceed; and, at different intervals, three other volumes were published, which not only established the reputation of their author in his native island, but, being translated into foreign languages, spread his fame through every quarter of the civilized world. The eminent service thus rendered by Dr Blair to the cause of religion and morality, was judged worthy of a public reward; and, in 1780, a pension of 200*l. per annum* was, by royal mandate, conferred on him, which he enjoyed till his death.

From this time, his bodily constitution, which had never been very robust, began gradually to feel the influence of age. In 1783, he found it expedient to decline the public duties of his situation as professor of rhetoric, and, some years afterwards, felt himself unequal to the fatigue of weekly appearances in the pulpit. The symptoms of decay, however, made no violent approaches; his mind remained strong and vigorous, and he continued to the last in the discharge of all the other duties of his situation. In the year 1793, on the death of his friend and colleague Dr Robertson, he was universally looked up to as the only person in every respect worthy to succeed that eminent man as principal of the university of Edinburgh. He himself considered that appointment as a tribute due to his fame, which it would have been honourable in the patrons of the university to bestow, but degrading in him to solicit; and when the election fell on another, he felt a severe mortification, which he did not affect to conceal.

Two years afterwards, a more painful trial awaited him in the death of a beloved wife, who, for the long period of 47 years, had been the faithful partner of his joys and sorrows. This lady, who was the daughter of his near relation, the Rev. James Bannatyne, one of the ministers of Edinburgh, was distinguished for the strength of her understanding, and the prudence of her conduct. By her he had a son, who died in infancy; and a daughter, who, though she did not survive her 21st year, displayed talents and dispositions worthy of such parents. These repeated shocks he sustained with the feeling of a man, and the resignation of a Christian. Dr Blair had now outlived the usual period of human life, and had the satisfaction of looking back on a long career, full of honour to himself, and usefulness to mankind. He foresaw, however, that the term of his earthly labours was fast approaching, and he resolved to spend the last of his days in a manner worthy of his former exertions, and of his well-earned reputation. The summer of the year 1800 found him employed, with all the ardour of his youthful years, in preparing materials for a new volume of sermons. Though now arrived at his 83d year, he, with his own hand, corrected and wrote out anew such of his unpublished discourses as appeared to him worthy of the public eye, and with much self-complacency he saw this arduous work completed before the commencement of winter. The intellectual vigour which on this occasion he displayed, proves the power-

ful influence of a well regulated mind in resisting the inroads of time, and surviving the wreck of the body. The period however was at last arrived, when the world was to be deprived of one of its brightest ornaments. On the morning of Saturday the 27th December 1800, in the 59th year of his ministry, after an illness of three days, which he bore with Christian fortitude, he expired, deplored by his native country, which his talents had so long contributed to adorn, and regretted by the whole Christian world, which, by his elegant instructions, he had delighted and edified.

The private character of Dr Blair is thus elegantly drawn up by his friend and colleague Dr Finlayson, in the account of his life subjoined to the posthumous volume of his sermons: "The reputation which he acquired in the discharge of his public duties, was well sustained by the great respectability of his private character. Deriving from family associations a strong sense of clerical decorum; feeling on his heart deep impressions of religious and moral obligation; and guided in his intercourse with the world by the same correct and delicate taste which appeared in his writings, he was eminently distinguished through life by the prudence, purity, and dignified propriety of his conduct. His mind, by constitution and culture, was admirably formed for enjoying happiness. Well balanced in itself, by the nice proportion and adjustment of its faculties, it did not incline him to the eccentricities, either of opinion or of action, which are often the lot of genius: Free from all tincture of envy, it delighted cordially in the prosperity and fame of his companions: Sensible to the estimation in which he himself was held, it disposed him to dwell, at times, on the thought of his success with a satisfaction which he did not affect to conceal: Inaccessible alike to gloomy and to peevish impressions, it was always master of its own movements, and ready, in an uncommon degree, to take an active and pleasing interest in every thing, whether important or trifling, that happened to become for the moment the object of his attention. This habit of mind, tempered with the most unsuspecting simplicity, and united to eminent talents and inflexible integrity, while it secured to the last his own relish of life, was wonderfully calculated to endear him to his friends, and to render him an invaluable member of any society to which he belonged. Accordingly there have been few men more universally respected by those who knew him, more sincerely esteemed in the circle of his acquaintance, or more tenderly beloved by those who enjoyed the blessing of his private and domestic connection."

That we may be able to form a more accurate idea of Dr Blair's merit as a preacher, and of the difficulties with which he had to contend, it may be proper shortly to advert to the state in which he found the eloquence of the Scottish pulpit. The reformation, which, in the sister kingdom, had been conducted with caution and timidity, under the immediate sanction and by the interference of the civil power, was in Scotland occasioned by the spontaneous impulse of public sentiment, which, with ungovernable fury, burst through every barrier opposed to it by the efforts of despotic power. It thus acquired, in its infancy, a character of harshness and enthusiasm which subsequent events tended to confirm. The bloody persecutions under Charles II. and his unfortunate and ill-advised brother, kindled afresh the dying embers of fanaticism, and, by a consequence extremely natural, cherished in the minds of the people an undue value for

those religious dogmas and forms of ecclesiastical jurisdiction for which they suffered. These circumstances, whilst they roused a spirit in the kingdom which the revolution of a century was not able to subdue, infused, at the same time, a peculiar tone of wildness and untutored vehemence into the eloquence of the public teachers. When Blair first commenced his clerical labours, one class of preachers still adhered to that bold, unseemly, and incoherent mode of declamation, which had been originally introduced by the early reformers, to inflame the imagination and rouse the passions of their rude and ignorant hearers. In their manner of delivery they were warm and violent; but their warmth had more the appearance of passion than of sentiment, and their violence approached nearer to the boisterous fury of the zealot than to the manly indignation of a generous and enlightened mind. With respect to the matter of their discourses, the range of their ideas was exceedingly circumscribed. The peculiar doctrines of the gospel were almost the only subjects on which they ventured to address their hearers; and these they usually treated in the same desultory manner, and enforced with the same hackneyed arguments. They delighted to confound by mystery, or overwhelm by terror, rather than to instruct by accurate reasoning, or edify by practical induction. This irrational and injudicious mode of instruction, adopted by the preachers of the old revolutionary school, gave rise, by a kind of repulsion, to an opposite class, who, despising the arts by which their brethren rose to fame, and aspiring after the approbation of more cultivated minds, fell too frequently into another extreme. In avoiding the awkward gestures, and untunable vociferation, which disgusted the well-educated hearer, they usually delivered their discourses with the immovable rigidity of a statue, and the tiresome monotony of a schoolboy. In adopting a more extensive field for public discussion, they often receded too far from the beaten track, and substituted for the doctrines and the precepts of the gospel a dry metaphysical dissertation, which few of their hearers could follow, or an elegant moral harangue, the reasonings and motives of which, not being drawn from the Christian system, were too affectedly refined to reach a common understanding, and too feeble to influence a common mind. This account of the eloquence of the Scottish pulpit serves strongly to characterise the genius of the nation at that period, when a sour, uncharitable, and bigotted temper, accompanied by a contempt for human learning, began to give place to a cheerful and enlightened piety, which introduced and fostered a predilection for polite literature, and a spirit of sober and rational discussion. The extremes, however, to which the two different classes of religious instructors carried their opposite peculiarities, served equally to bring into discredit the principles of genuine Christianity. Whilst the loose and enthusiastic rhapsodies of the one was a subject of ridicule to the sceptical and profane, the suspicious and lukewarm conduct of the other, in the total rejection, and the stinted and cautious use of scriptural doctrines, was to the sincere believer a ground of serious regret and well-founded alarm. Such however was, with some exceptions, the situation of the Church of Scotland, before Dr Blair commenced his public labours, and gave a more chaste, correct, and happy form to the method of religious instruction in Scotland. This accomplished preacher seems, in many respects, to have hit that happy medium at which all pretended to aim.

but which few had the good fortune to reach. Uniting the learning and elegance of the polite scholar with the tenderness, the warmth, and the energy of the Christian teacher, he has arrayed truth in her most lovely and venerable garb, and given to her form all the captivating influence of its native attractions. In the composition of his sermons, we discover the regular and well-digested plan of the logician joined to the splendid beauties of the orator; in his sentiments, we find the ingenious reasoning of the philosopher blended with the sublime and enlightened views of the Christian. If, however, the severe eye of criticism were disposed to examine the discourses of Dr Blair by the standard of perfection, it might perhaps be able to point out some deficiency in the execution of that part of his duty, which more peculiarly belonged to him as a preacher of the gospel. Scriptural doctrines do not always appear to have been illustrated by him with sufficient attention, nor scriptural motives to have obtained a place due to their importance; and too strong a bias may perhaps be observed, in his writings, in favour of moral discussions, abstracted from the consideration of the truths inculcated by revelation. See *A short account of Blair's Life and Writings*, by Dr Finlayson, subjoined to the fifth volume of *Blair's Sermons*; and a separate and more extended account, by Professor John Hill, LL. D. (H. D.)

BLAKE, ROBERT, a celebrated English admiral, was born in the month of August 1598. His father, Mr Humphry Blake, was a Spanish merchant, who had made a considerable fortune, and purchased a small estate in the neighbourhood of Bridgewater, where his family had long been settled. Robert was sent to a free school in that town, and afterwards removed to Oxford, where he prosecuted his studies for seven years, being a member, first of St Alban's Hall, and then of Wadham College. He took a degree before leaving the university; but was unsuccessful in the pursuit of academical preferment. During his residence there, he displayed that temper which afterwards became more conspicuous in his political conduct. Though a humourist, and, in that character, extremely agreeable to the jovial companions with whom he associated, his humour was strongly tinged with sarcastic severity; and, while he pleased his friends by his cheerfulness, he gratified his own censorious propensity, by attacking the pride of courtiers, and the arrogance of churchmen.

In the parliament which sat in April, 1640, he took his place as a burgess for Bridgewater. This honour he owed to the Puritans, who promoted his views on account of his integrity, his dislike to persecution, and his strong leaning to the cause of liberty. But he had no opportunity then of shewing what talents he possessed as a senator; and in the long parliament which succeeded he lost his election.

When the civil war broke out, he declared for the parliament, and soon took arms in its support. As an officer, he displayed great military talents. He was employed on every occasion which particularly called for dexterity or courage; and recommended himself so much by his able and zealous services, that, in 1644, he was appointed governor of Taunton, in Somersetshire, a place which he had taken by surprise, and which was of the utmost consequence to the parliament, being the only garrison they possessed on that side of the island. Here he was besieged by General Goring, at the head of 10,000 men; but he, and his gallant handful of troops, made such an obstinate and successful resistance, that

the parliament bestowed upon them a handsome pecuniary reward. While he held this honourable appointment, he shewed his devotedness to the cause which he had espoused, by joining in an address of thanks to the House of Commons, for resolving that no more addresses should be presented to the king. The last military achievement which he performed, was reducing Dunster castle, a seat belonging to the ancient family of Lutterel, from which the king's troops frequently sallied forth, to the great annoyance of the surrounding country.

Hitherto Blake had not signalised himself more than many others who were engaged in the same enterprise; but the time was now arrived, when he was to enter on a new scene of exertion, to stand alone and unrivalled in a most important branch of the public service, and to add fresh lustre to his own reputation and to that of his country. On the 12th of February 1649, he was appointed one of the commissioners of the navy; and a few days after, an act was passed, nominating him, in conjunction with Deane and Popham, who were likewise land officers, to the command of the fleet. With our ordinary ideas of naval duty, it seems a strange transition, to pass, without any professional preparation, from the colonelcy of a regiment, or the government of a town, to the difficult and important situation of an admiral, who must not only be acquainted with the mere act of fighting, but also with the practice of common navigation, and the principles of maritime tactics. Strange, however, as the transition appears, and unlikely to contribute to the advantage of the state, it succeeded so well in this case, that those who made it soon became more eminent than almost any who had preceded them, and acquired for themselves a name which will ever adorn the naval annals of the country. With regard to Blake, in particular, he seems to have been a man distinguished by that original force of mind, that natural quickness of apprehension and dexterity of powers, which enables the individual, by whom it is possessed, to acquire any species of knowledge with facility, and to apply it to practical purposes with wisdom and effect. There was, besides, in Blake, a peculiar energy of character, which, commanding respect as soon as it was observed, would soon reconcile those who were under him to his authority, induce them to overlook his want of technical science, and make them not only anxious to aid his endeavour in acquiring what he thus needed, but also willing to confide in his decisions, and ready to carry them into execution.

The first service which Blake performed after he took the command of the fleet, was delivering the coasts of Britain and Ireland from the depredations of Prince Rupert. This prince continued cruising in a piratical way, and making prizes throughout the greatest part of the year 1649. The parliament, as soon as affairs became more favourable to them in Ireland, gave orders to Blake and Popham to block up the prince's squadron in the harbour of Kinsale. This was done in the most effectual manner; and to such extremities was Rupert reduced, that his men began to desert in great numbers; which circumstance, along with the desperate state of the royal cause, made him resolve to force a passage through the parliament's fleet. He carried his resolution into effect with the loss of three ships, and made the best of his way to the coast of France, and from thence sailed towards the Mediterranean, obstructing and injuring the trade of England by a system of privateering, as disho-

nourable to him as it was hurtful to the trade of the commonwealth. Blake, having been sent after him, arrived at St Andero, from which place he wrote a letter to the king of Spain, requiring that such of Prince Rupert's ships and men as were in his power should be delivered up, and threatening vengeance in case of refusal. To this requisition, his catholic majesty returned a civil answer, and accompanied it with a ring worth 1500*l.*, as a mark of his respect for the admiral. Blake then followed Rupert into the Tagus, where he destroyed the Brazil fleet. The prince being, in consequence of this, forced out of the river, betook himself first to Carthagen, and then to Malaga, where Blake attacked him, and destroyed all his ships excepting two, which he himself and his brother Maurice commanded. This event is said to have occasioned considerable alarm in the different courts Europe. But it produced the most sensible effect in those of Spain and Portugal, which immediately sent ambassadors to England, to acknowledge the power of the parliament.

On his return home, Blake was cordially received by the Parliament, in whose cause he had made such gallant exertions. He was honoured with the thanks of the House; and as a farther expression of their gratitude to him for the past, and of their confidence in him for the future, they again conferred upon him, in conjunction with Deane and Popham, the supreme command of the fleet. In the course of the year 1651, he reduced the islands of Scilly, Jersey, and Guernsey, which had been held for the king, and which were extremely injurious to the country, on account of the great number of privateers that they harboured.

In the year 1652, war broke out with Holland, and Blake was constituted sole admiral. On the 18th of May he fell in with the Dutch fleet, commanded by Van Tromp. Though he had no more than 15 vessels to contend against 42, he not only did not decline an engagement, but actually gained a victory, capturing two of the enemy's squadron, and disabling a third; and, in consequence of a reinforcement of eight ships under Major Bourne, obliged them to consult their safety in flight.

In the beginning of July he sailed to the north, for the purpose of destroying the Dutch herring fishery, which he imagined would convince the States, more than many defeats, of the absurdity and danger of disputing with England the sovereignty of the seas. He found the fishing vessels under the protection of 12 men of war. A stout battle took place with the convoy, which ended in the capture of the whole. The fishery of course was left entirely to Blake's mercy. He treated those who were engaged in it with great humanity, but at the same time in such a manner as to impress upon their minds a strong sense of the maritime power and greatness of England. In his way home he took five or six frigates belonging to the Dutch fleet under Tromp, which had sailed to intercept him, but had been dispersed in a storm. After his return, he did great mischief to the enemy in the channel. And, in consequence of some hostilities which the French had committed at Newfoundland, he attacked a strong squadron, which they were sending to the relief of Dunkirk; and, having taken or destroyed them all, that place fell easily into the hands of the Spaniards. On the 28th of September he engaged the Dutch admirals De Witte and De Ruyter. A well-contested battle ensued. It ended in the defeat and flight of the Dutch. For this Blake received

the thanks of the parliament. In his next encounter with them, however, which happened on the 29th of November, he was not so successful. Thinking that the season of action was over, he had detached above 40 of his ships to different stations; and the Dutch admiral hearing of this, seized the opportunity of attacking him near Dover Road with his whole force. Blake fought with his usual valour and obstinacy; but superiority of numbers at length prevailed, and, after suffering considerable loss, he was under the necessity of profiting by the darkness of the night, and retiring into the Thames. The parliament, hearing the real cause of the disaster, caressed the admiral as formerly; again appointed him to the command; and, in six weeks, provided him with a fleet of 60 ships of war. On the 18th of February 1653, he fell in with Tromp, who had a fleet of about the same numerical strength, and between 200 and 300 merchantmen under convoy. Tromp was surprised to find the English admiral so soon in a condition to meet him, and would probably have been glad to avoid fighting; but Blake was so stationed across the channel, that it was impossible to escape a battle. The battle lasted for two days, and was even renewed in the morning of the third, when Tromp, finding that nothing was to be expected from farther resistance, but the destruction of his fleet, thought proper to sheer off to Calais, from whence he cautiously coasted it home, our fleet pursuing slowly, and picking up the straggling ships. Blake was wounded in the first day of the action. On the whole, the Dutch lost, on this occasion, 11 ships of war, 30 merchantmen, and about 3000 killed and wounded. The English suffered about as much in men, but lost only one ship.

On the 20th of April, Oliver Cromwell dissolved the parliament by force, and assumed the supreme power. Blake's feelings and prepossessions were in favour of a commonwealth. He had lent his aid in giving vigour and respectability to that which had been lately established in England, and would, no doubt, feel a lively indignation at the violent and unexpected change which had taken place. But Blake loved his country better than any thing else. At this moment he saw her exposed to the attacks of powerful enemies. He was sensible, that any attempts to rekindle a civil war, or to set the naval and military forces at variance, would have endangered her independence. And, therefore, to preserve her strength unbroken, and her councils undivided, so far as his personal influence extended, he continued his efforts against the common foe, saying, to those under his command, "It is not for us to mind state affairs; but to keep foreigners from fooling us." Such conduct made him a favourite with all parties, because it showed that he was a true and steady patriot. The town of Bridgewater returned him as their representative to the new parliament; and even Cromwell himself, to whom his republican sentiments, and unbending spirit, were perfectly well known, regarded him with affection, and treated him with confidence. He acted thus, because he was convinced, that Blake was influenced by views which looked farther than the advancement of any political faction, and would make greater exertions, from a pure regard to the welfare and glory of England, than others would do from all the motives of interest and ambition.

On the 2d of June, the English fleet, under Monk and Dean, attacked that of the Dutch under Van Tromp. Each consisted of about 100 ships of war. The action

commenced at eleven in the forenoon, and continued with great warmth through the remaining part of the day. It had not lasted, however, many hours, when the enemy began to give way and fall into confusion. The arrival of Blake during the night, with 18 sail, decided their fate. For, next day, after Tromp had attempted, in vain, to avoid a renewal of the contest, a second engagement took place, in which, after a long and furious struggle, the Dutch were completely defeated, with immense loss both in ships and men. This, together with some other serious disasters which befel their trade and their navy, hastened on the negotiations between Cromwell and the States, and led to the peace which was concluded on the 4th of April 1654.

After the conclusion of the Dutch war, Cromwell ordered his navy to be repaired; and sent Blake with a considerable fleet into the Mediterranean to support the honour of the English flag, and to take vengeance on those powers by whom it had been insulted. This important commission he executed with his wonted spirit and success. The terror of his name commanded respect almost every where; and, when submission did not follow, he exacted it by force of arms. Several facts are recorded, which show how much he was feared. While he continued in the Road of Cadiz, where he arrived in the beginning of December, the Spaniards behaved to him with the greatest reverence and civility. A Dutch admiral, who happened to be there, would not venture to hoist his flag till Blake's departure. One of his tenders happening to be separated in a storm, was stopped by a French squadron; but the admiral, as soon as he learned to whom the tender belonged, brought the captain on board his own ship, drank Blake's health before him under a discharge of five guns, and then dismissed him. The Algerines, too, were so much afraid of him, that they stopped the Sallee rovers, and obliged them to deliver up the English prisoners in their possession, whom they immediately sent to Blake to conciliate his favour.

From Cadiz, Blake sailed to Malaga; and, while in that port, an incident occurred, which served to place his peculiar temper and character in a striking point of view. Some of the sailors, who happened to be ashore, met the host as it was carried along the street, and not only refused to pay it any respect, but, with their characteristic thoughtlessness and humour, fell a laughing at the superstition. Upon this, the people, instigated by their priest, attacked the sailors, and beat them severely. They complained to the admiral, who instantly became very indignant, and sent a message to the viceroy, to demand the offending priest. The viceroy answered, that he had no authority over the priests. Blake then sent a second message, declaring, that it did not lie with him to determine who should send the priest; but that, if he was not sent, he would most certainly burn the town about their ears. The inhabitants hearing this threat, compelled their viceroy to send the priest, who, when he came before the admiral, excused himself, on account of the behaviour of the seamen. Blake told him, that if he had complained of the injury, they should have been punished; for he did not allow his men to insult the established religion of any place; but that he did wrong in stirring up a mob of Spaniards to beat them, and "that he would have him, and the whole world know, that none but an Englishman should chastise an Englishman."

We have mentioned, that the Algerines showed

some marks of submission to the admiral. They had sinned, however, too deeply against England to be forgiven on account of such partial oblations. Blake, therefore, appeared before Algiers on the 10th of March, and sent an officer ashore to demand satisfaction for the piracies which he had committed against English ships, and the release of all the Englishmen whom they held in captivity. The Dey complied, as far as was possible, with the terms prescribed; promised the redemption of the prisoners, who were now private property, on the most easy terms; and offered to make a treaty with him, engaging to commit no hostilities against the English in future.

He next sailed to Tunis; there, however, the Dey not only refused his demands, but would not permit him to take in fresh water. "Here," said he, "are our castles of Colletto and Porto Ferino; do your worst." Blake, on hearing this, was highly incensed; and, according to his custom on such occasions, began to curl his whiskers. Having shortly consulted with his officers, he entered the Bay of Porto Ferino with his large ships, bore up within musket shot of the castle, from which 60 guns played on him at once, and opened such a tremendous fire, that, in two hours, he dismounted their artillery, and rendered the works quite defenceless. He also gave orders to attack and destroy all their shipping in the road, which service was gallantly performed, with the loss of above 70 men killed and wounded. From Tunis he went to Tripoli, where the government readily consented to liberate the English captives, and to conclude a peace. And returning thence to Tunis, he obliged the Tunisians to implore his mercy, and to beg of him a peace, which he granted, on terms equally mortifying to them, and advantageous for England. He also paid a visit to Malta, and compelled the knights to restore the effects which their privateers had taken from the English. By these daring enterprises, and successful exploits, he made his own name formidable, and so elevated the character of his country, that most of the Italian states sent solemn embassies to England to compliment his master, the protector.

Blake was in the Road of Cadiz, living on the best terms with the Spaniards, when intelligence came of the capture of Jamaica, and consequently of a Spanish war. In compliance with instructions from the protector, he watched the arrival of a Plate fleet that was expected, and succeeded in intercepting it. After cruising for a considerable time on that station, he heard that another Plate fleet had put into the Bay of Santa Cruz, in the island of Teneriffe. He immediately set sail with 25 ships, and came to his point of destination on the 20th of April 1657. The Spanish ships, amounting to 16, of which 6 galleons were laden, were placed in a most secure and formidable position. They were not only capable of making an obstinate defence by their own strength, but also protected by a castle, which stood at the mouth of the haven, and was well supplied with heavy ordnance, and by seven forts situated round the bay, and joined by a line of communication, which was manned with musketeers. The Spanish governor thought himself quite safe; and was so confident of the excellence and sufficiency of his dispositions, that when the master of a Dutch ship, knowing the certainty, and dreading the consequences of an attack, asked leave to depart, he answered, angrily, "Get you gone, if you will, and let Blake come, if he dares." Blake called a council of war, in which it was determined to attempt the de-

struction of the enemy's ships, as it was impossible to bring them off. The attempt was made, and attended with perfect success. An attack was directed at the same time against the forts and the fleet; and the enterprise was so skillfully and gallantly conducted, that, in a few hours, the forts were abandoned by the Spaniards, and their fleet boarded and carried by the English, who burnt every ship to ashes, except two that were sunk. Had the wind which carried him into the bay continued to blow much longer in the same direction, Blake could scarcely have escaped; but fortunately it changed, and brought him safely out, leaving the Spaniards in astonishment, that he should, in such perilous circumstances, have dared to attack them, and that he should have succeeded so completely in accomplishing his object. Lord Clarendon tells us, that every body who knew the place, wondered that any sober man, whatever might be his courage, could think of such an undertaking; that the English could hardly persuade themselves to believe what they had done; and that the Spaniards took comfort, from the idea that they were devils and not men who had destroyed them in such a manner. At the same time, this event so subdued the spirits of the Spaniards, that afterwards, when opposed to the English, they had no dependence either upon numbers, or valour, or fortifications. We must not omit to mention a circumstance that occurred on this occasion, which was indicative of the disinterested zeal of Blake for the naval service, as the enterprise out of which it sprung was honourable to his ability and courage. His brother, captain Benjamin Blake, for whom he entertained the warmest affection, had been guilty of some misconduct in the action. This being observed by the admiral, he sacrificed his private feelings to his sense of public duty, by removing his brother from the ship, and giving the command of it to another officer.

After this, Blake cruised for a short time off Cadiz; but finding his ships getting foul, and his own health gradually wearing away by a complication of dropsy and scurvy, he set sail for England. This distemper grew upon him during his passage home, and cut him off before he reached his native soil, on which he had shown a strong desire to draw his last breath. He died as his ship entered Plymouth Sound, on the 17th of August 1657, being about 59 years of age. His body, after lying in state for several days in Greenwich Hospital, was conveyed to Westminster Abbey, and interred in a vault, built on purpose, in the chapel of Henry VII. The funeral was magnificent. It was attended not only by his friends and relations, but by the protector's privy council, the commissioners of the admiralty and navy, the lord mayor and aldermen of London, the field officers of the army, and a vast number more of quality and distinction. But the loss was public. The country at large felt, that they had been deprived of a hero and a friend; and expressed, in the language of universal regret and sorrow, the high sense which they entertained of his services as an admiral, of his worth as a patriot, and of his virtues as a man. Blake, in truth, was a rare character. No Englishman can read the history of his life without admiration and delight. We know of one only, in the naval records of Britain, whom we can willingly place before him.—we mean the late lord Nelson; between whom and Blake, indeed, there are many points of resemblance, which the reader may easily trace. It may even be safely as-

serted, that the past and present maritime superiority of this empire, took its origin from the skill and bravery of Blake, who showed his country what they were capable of accomplishing at sea, and taught all Europe, and more than Europe, to tremble at the British flag; and infused a spirit of greatness into the navy, which it never possessed before, and which has animated and upheld it ever since. See Campbell's *Lives of the British Admirals*. Clarendon's *History of the Rebellion*. Whitaker's *Memorials*, &c. (τ)

BLAKEA, a genus of plants of the class Dodecandria, and order Monogynia. See BOTANY. (ω)

BLANC, MONT, a lofty mountain in France, and the highest of the Pennine Alps, is situated in the duchy of Faucigny, formerly a part of the king of Sardinia's dominions, but now subject to the emperor of France. It receives its name from the immense mantle of snow, with which its summit and sides are covered, and which is estimated to extend not less than 12,000 perpendicular feet, without the least appearance of rock to interrupt its glaring whiteness.

When viewed from the Col de Balme and the vale of Chamouni, its summit seems to be of a roundish form, its surface smooth and covered with snow, its whole appearance uniting beauty with grandeur, and its towering head rising majestically above the surrounding mountains; but, when seen from the valley of Aost, its sides are less completely covered with snow, its aspect more rugged and dark, and the prospect which it presents partakes more of the wild and terrific. It rises imperceptibly from amidst the numerous irregular mountains, which bound the vale of Chamouni, then terminates rather abruptly in a point or top called *Aiguille de Goute*, or *Dôme de Gouté*. Beyond this height, with a considerable hollow between, it forms another mount, called by some *Little Mont Blanc*, or more properly *The Middle Dome*. From this station it gradually sinks again into a concave surface, in the midst of which is a small pyramid of ice; and then reaches its highest point of elevation, which is in the shape of a compressed hemisphere, and is called from its form *La Bosse du Dromédaire*. Upon a nearer inspection, the summit of this gigantic mountain is found to be a very narrow ridge, lying nearly in a horizontal direction, resembling the roof of a house; and at its west end particularly, scarcely sufficiently broad to admit of two persons walking abreast. The snow, which covers the top, is encrusted with ice, of a firm consistence, but penetrable by a staff; and beneath this icy surface, especially on the declivities of the summit, is discovered a soft dusty snow without any cohesion.

The highest rocks of Mont Blanc are formed of strata of granite, running parallel to one another, and nearly in a vertical direction. Those on the east side are mixed with steatites; those on the south with schœrl and lapis corneus; and some of them, about 150 yards below the summit, have the appearance of having been silvered with lightning.

Mont Blanc is unquestionably the highest mountain in Europe; and there is no reason to think that it is surpassed by any in Africa or Asia. According to the calculations of De Luc, its height above the level of the sea is 2391 $\frac{1}{2}$ French toises, or 15,304 English feet; according to Sir George Shuckburgh, 15,662 feet; and according to other observations, 15,680 feet, or nearly three English miles above the level of the sea.

At the elevation of 11,392 feet above the sea, M. De

Saussure observed the *silene acaulis*, or moss campion, in flower; still higher, on the most elevated rocks, he found the *lichen sulphureus* and *lichen rupestris* of Hoffman; and, on the summit, he noticed two butterflies on the wing, which he supposed to have been driven thither by the wind. On the top of Mont Blanc, on the third day of August, Reaumur's thermometer stood, in the shade, at $2\frac{3}{10}$ below the freezing point, or 27 of Fahrenheit; while, at the same time, at Geneva, it was found at 22.6 or 83 of Fahrenheit, which gives a difference of nearly 25 degrees of Reaumur, or 45 of Fahrenheit, between the temperature of the atmosphere at both places. De Luc's barometer fell to $16.0\frac{1440}{1600}$, while it stood at Geneva at $27.2\frac{1085}{1600}$, a difference of 11.2, with a small fraction. By experiments with the hygrometer, the air was found to contain six times less humidity than that of Geneva; and to this extreme dryness of the atmosphere, the burning thirst, which Saussure and his companions experienced in the extraordinary elevation, is supposed to have been owing. While 15 or 16 minutes are sufficient to boil water at Geneva, and 14 or 15 at the sea side, it requires half an hour on the top of this mountain. By experiments with the electrometer, the electricity of the air was found to be positive, and the balls diverged only three lines; and by experiments with lime water, and the caustic alkali, atmospheric acid, or fixed air, was detected in the atmosphere. Owing to the extreme rarefaction of the air, sounds were remarkably feeble, and the report of a pistol discharged on the summit, did not exceed that of a small Chinese cracker in a room. From the same cause, respiration becomes exceedingly difficult at so immense an altitude; and it was found, that the pulses of three persons, which beat at Chamouni, in a state of repose, 49, 60, and 72, were increased, on the summit of Mont Blanc, to 98, 112, and 100.

The ascent of this lofty mountain is particularly hazardous and toilsome; and in consequence of repeated failures on the part of those who made the attempt, was for a long time deemed utterly impracticable. A short sketch of these adventurous excursions may not be uninteresting to our readers; and may enable them (better than any description can do) to form a livelier conception of the amazing height and wintry horrors of Mont Blanc. The first attempt was made by M. Couteran, and three guides of Chamouni, Michael Paccard, Victor Tissay, and Marie Coutet. They set out from the priory about eleven o'clock in the evening, on the 13th of July 1776; and after spending 14 hours in surmounting many dangerous ascents, crossing vallies of ice, and traversing plains of snow, they reached the top next to Mont Blanc, about 13,000 feet above the Mediterranean. They at first imagined themselves to be within a league of its summit; but soon perceived, that it would require other four hours to reach it; and as the day was far advanced, and the vapours gathering into clouds, they were obliged, with regret, to relinquish their enterprise; and, after a journey of 22 hours, arrived at Chamouni about eight o'clock in the evening. The indefatigable Bourrit next excited a spirit of enterprise among the inhabitants of Chamouni; and after repeated unsuccessful attempts, he departed from Bionasay on the 11th of September 1784, accompanied by six guides, and was *scaling*, as he expressed it, the *rampart* of Mont Blanc, when he was so extremely affected by the intensity of the cold, as to be unable to proceed. But two of his guides, Marie Coutet, and Francis Guidet,

having gone before their company, ascended to the *dome* of Gouté; passed the middle dome, and walked along the ridge between that and the summit, as far as some high rocks, which appear from the vale of Chamouni like small points in the snow; but the approach of night compelled them to return. On the 4th of September 1785, Marie Coutet, and James Balma, reached a place under a rock at a considerable elevation, where they passed the night; and setting out before sun-rise, passed the dome of Gouté, and were proceeding towards the summit, when a violent storm of hail obliged them to desist. On the 13th of September, Messieurs de Saussure and Bourrit, with twelve guides, left Bionasay, passed the night at a hut, which they had ordered to be constructed, about 7808 feet above the level of the sea, and reached the dome of Gouté next morning without much difficulty; but a fresh fall of snow rendered farther progress impracticable. In July 1786, six guides of Chamouni failed in another attempt; but James Balma, one of their number, having been separated from his companions, passed the night in a spot above the dome of Gouté, more than 12,000 feet above the level of the sea; and, having reconnoitred the situation next morning, observed a place of more easy access than any that had hitherto been attempted. On his return to Chamouni, he communicated his observation to Dr Paccard, a physician of the place, who attended him during a severe indisposition, the effect of the cold and fatigue to which he had been exposed; and in gratitude for that gentleman's attendance, engaged to conduct him to the summit of the mountain. They set out from Chamouni on the 7th of August, spent the night on the mountain of *La Côte*; at three in the morning pursued their route to the dome of Gouté; passed under the middle dome towards the east, along the ridge which is seen from Geneva, and which lies on the left of the summit. Here Dr Paccard was almost deterred by the cold and fatigue from pursuing the enterprise; but encouraged by Balma to proceed, and frequently walking sideways to shelter their faces from the piercing wind, they at length, about six o'clock in the afternoon, and after an ascent of 15 hours, attained the summit of Mont Blanc. They remained about half an hour on a spot, which no one before them had been able to reach, and where the cold was so intense as to freeze the provisions in their pockets, congeal the ink in their inkstands, and sink the mercury of Fahrenheit's thermometer to $18\frac{1}{2}$ degrees; their faces were excoriated, their lips swelled, and their sight greatly debilitated by the reflexion of the snow. On the 15th of August 1787, M. de Saussure set out from Chamouni, accompanied by 18 guides, and provided with a tent, mattresses, philosophical instruments, and all necessary accommodations. They passed the first night on the top of the mountain *La Côte*; encamped at four o'clock in the following afternoon, about 12,762 feet above the level of the sea; and next morning pursued the ascent in places frequently so steep, that the guides were obliged to hew out steps with a hatchet. After a very slow progress, and frequent halts for breath, they reached the summit about 11 o'clock in the forenoon; where they remained $4\frac{1}{2}$ hours, enjoying a most sublime and extensive prospect, and making a variety of useful and interesting experiments. Here they observed the surrounding mountains, not in regular lines and continued ridges, as they appear when viewed from the plain; but in the most irregular groups and insulated masses; connected

indeed at their bases, yet completely detached from each other, distinct in the forms, and separated at their summits. In this elevated station, they experienced great difficulty of respiration, which was increased by the slightest exertion, by a stooping posture, and by the use of wine or brandy; were kept in a state of continued fever, and tormented with a burning thirst; felt no appetite for food, no relish for strong liquors, no relief in any thing but in draughts of fresh water. About two o'clock in the afternoon they began to descend; and arrived next morning, without any accident, at the valley of Chamouni. On the 8th of August, a few days after Saussure's expedition, Mr Beaufoy, an English gentleman, succeeded in a similar attempt; but on account of the enlargement of the chasms in the ice, it was accomplished with greater difficulty. See Coxe's *Travels in Switzerland*, vol. 2. Saussure's *Voyages dans les Alpes*, vol. 4. Martyn's *Sketch of a Tour through Switzerland*, App. (g)

BLANC, MONT, the name of one of the new departments of France, formed out of Savoy. It is bounded on the east by the Alps, on the south by the department of the Upper Alps, and the department of the Doire, on the west by the departments of the Aix and the Isere, and on the north by the department of Lemane. The principal rivers of this department are the Arc, which runs from south-east to north-west, and joins the Isere, near Mont Meillan; the Isere, which, rising in the Alps, runs from north-east to south-west; and the Guyers, which passes the bridge of Beauvoisin. The general aspect of this department is by no means beautiful; but it abounds in iron, copper, silver, lead, and coal. Probably, on account of the want of wood, the mine of St Georges-d'Heurtres is the only one which is actually worked. It employs nine large furnaces for the smelting of iron. The forests occupy 112,000 hectares, or from 218 to 219 arpens, and belong almost wholly to the communes. Superficial extent 1,254,796. Contributions in 1803, 1,148,533 francs. Population 283,106. The principal towns are, Chambery, the capital; Annecy, St Jean de Maurienne, and Moutiers. (w)

BLANCHING. See GARDENING.

BLANDFORD, an ancient town of England in Dorsetshire, situated on the river Stour, near the Downs. The streets are handsome, and the houses, which are of brick, are generally well built. The principal buildings are, a church, in the Grecian style, 120 feet long, and built in 1739; and a townhall, built with Portland stone, on columns of the Doric order. This town has suffered severely by fire, before 1579, in 1677, in 1713, and in 1731. Near Blandford stood the famous Damary oak, which was rooted up in 1755. It measured 75 feet in 1797; the branches extended 72 feet; the trunk was 12 feet in diameter, and 17 feet above the earth; and the circumference of the bottom was 68 feet. In the cavity, which was 15 feet wide, an old man lived during the civil wars, and till after the Restoration. The only manufactures here are one of shirt and waistcoat buttons, and one of thread. Number of houses 405. Population 2326; of whom 480 were returned as employed in trade and manufactures. See Hutchinson's *History of Dorsetshire*. (j)

BLARNEY, a market town in the province of Munster, celebrated for several manufactories established in it by Mr Jeffries, to whom it belonged. Several of them have now fallen into decay, and the only ones which now

exist, are a paper mill, a stamping mill, a bleaching establishment, and one or two cotton manufactories. See Mr A. Young's *Tour through Ireland*. (j)

BLASIA, a genus of plants of the class Cryptogamia, and order Algæ. See BOTANY. (w)

BLAST FURNACES. See IRON.

BLASTING OF ROCKS, is an operation of great importance in the formation of roads, or in the breaking up of uncultivated ground.

The process of blasting rocks, or stones, consists in boring a cylindrical hole, about 10 or 12 inches deep, in the rock, by means of a chisel for that purpose. The lower part of this hole is filled with gunpowder. The upper part of the hole is then filled up with fragments of stone, firmly rammed together; a hole being left through these materials, by the insertion of an iron rod, which is turned round during the operation of ramming. This hole is next filled with powder, and a match is applied to it in such a manner, that the operator has time to run out of the reach of the fragments of the rock.

This process, which is both tedious and dangerous, is now abandoned for one which is more simple and effectual, and which consists merely in introducing a straw, filled with gunpowder, among the powder at the bottom of the cylindrical hole in the rock, and filling the rest of the cylindrical hole with loose sand. By applying a match to the gunpowder in the straw, an explosion takes place; and, instead of the loose sand being driven out of the cylindrical hole, as might naturally be expected, the rock is completely shivered in pieces. Mr Jessop tried the experiment with great success on some of the hard rocks at Fortwilliam, and also on the lime works at Bristol.

Mr Farey mentions his having witnessed, near Aylesbury, a method of blasting large rocks without gunpowder. The rock was undermined for about a yard in length, and half a yard in depth, and a small faggot of brushwood, furze, or a bundle of straw, was introduced into the cavity. As soon as it was set on fire, the expansive force of the air, confined in the stone, burst it into innumerable fragments.

Mr Headrick proposes to blast rocks by introducing the purest quicklime into the cylindrical hole, instead of gunpowder. By suddenly slaking the lime, he conceives, that the expansive force would rend the stone in pieces. See Nicholson's *Journal*, vol. x. p. 230.; vol. xi. p. 241. *Communications to the Board of Agriculture*, vol. ii. *Philosophical Magazine*, vol. xx. p. 208. (g)

BLASTING SCREW, the name of a simple apparatus for blasting logs of wood by the explosion of gunpowder, invented by Mr Richard Knight. The instrument is a screw, having a small hole drilled through its centre. When a log of wood is to be split, a cylindrical hole is bored, to a proper depth, with an augur, and a quantity of gunpowder introduced. The screw is then screwed into the cylindrical hole, till it nearly touches the powder, and a match is put down through the hole in the screw till it touches the charge. This match, which is about 18 inches long, and made of twine or linen thread, steeped in a solution of saltpetre, is then set on fire, and the log is broken in pieces. See *Transactions of the Society of Arts*, for 1802; and Nicholson's *Journal*, vol. v. p. 31. (π)

BLATTA, a genus of hymenopterous insects. See ENTOMOLOGY.

BLEACHING.

BLEACHING, is the art by which those manufactures which have vegetable substances for their raw material, are freed from the colouring matter with which such substances are naturally combined, or accidentally stained; and the pure vegetable fibre, deprived of these coloured matters, is left to reflect the different rays of light in due proportion, so as to appear white.

Besides the spoils of animals, mankind, to supply their natural want of covering, have, in all countries, had recourse to vegetable substances, preferring those whose fibres excelled in strength, durability, and pliancy; and experience having proved, that flax and cotton were well adapted to such purposes, these substances have been very generally adopted, and formed into such cloths as the skill and industry of the weavers could execute.

It would soon be observed, that the action of water, together with that of the sun and air, rendered those rude cloths whiter than they were at their first formation; and, since the first step towards refinement is to add beauty to utility, as the state of society improved, a desire to give them a pure and spotless white would naturally arise. The idea of white raiment being the emblem of innocence and peace, which seems to have been very early entertained, would make every means for facilitating the removal of natural or adventitious stains more earnestly studied.

Accident would probably discover, that a certain degree of putrid fermentation carried off colouring matters from vegetable fibres. Hence the practice of macerating cloth in water, mixed with putrid urine, and the dung of domestic animals, which has been continued to our days.

* As the facts respecting the introduction of the new method of bleaching are not generally known, and have been greatly misrepresented by some late writers on that subject, we shall make no apology for laying them before our readers.

The first attempt to apply the oxymuriatic acid to the art of bleaching appears to have been made by Berthollet, about the year 1786, (*Ann. de Chim.* ii. 160.) Influenced by the most liberal views, he made no secret of his experiments; and exhibited some of them in presence of Mr Watt of Birmingham, who was instantly impressed with the importance of the discovery, (*Id.*) Early in the year 1788, an attempt was made by some foreigners to obtain a parliamentary grant; and, failing in that, a patent right, for a new method of bleaching, which they professed would shorten the process, and reduce it to a few hours. Mr Watt, however, having been made acquainted with Berthollet's discovery, and having actually applied it in practice to the whitening of 500 pieces of cloth, resisted this monopoly; and was joined by Mr Cooper† and Mr Henry of Manchester, both of whom had also been successful in their attempts to apply the acid to the bleaching of cotton goods, though their experiments were conducted on a smaller scale. The opposition was effectual, and the foreigners were foiled in their attempt to obtain a patent.

Owing most probably to his distance from the seat of the cotton manufacture, Mr Watt did not himself embark in the practice of bleaching. Mr Cooper, however, formed an establishment for the purpose of applying Mr Berthollet's discovery; and Mr Henry not only engaged in a similar undertaking, but gave, to some of the principal bleachers in this country, the first instructions which they received respecting the new process. The method of the latter gentleman at first consisted, sometimes in immersing the goods in a watery solution of the gas, or in an alkaline ley impregnated with it, and sometimes in exposing the goods, previously moistened with water, to the action of the gas itself. Soon afterwards he made a further improvement, in substituting lime for alkali, as a means of condensing the oxymuriatic acid gas. An air-tight chamber was prepared, on the floor of which rested a stratum of lime and water, mixed together to the consistence of cream. Through this the goods were passed by means of a winch; and the chamber being filled with gas, the goods were alternately exposed to the lime liquor, and to the acid vapour. Thus an oxymuriate of lime was formed upon the cloth, which, after a sufficient continuance of the operation, was taken out, and exposed to the usual processes of washing, &c.

A very essential improvement in the application of lime was, some years afterwards, discovered by Mr Tennant of Darnley, near Glasgow, and was secured to him by a patent, dated January 30, 1798. It consisted in effecting a combination of oxymuriatic acid with lime, in a separate vessel, containing lime suspended in water by mechanical agitation. The redundant lime was allowed to subside, and the clear liquid, a solution of oxymuriate of lime, applied, properly diluted, to the purpose of bleaching. It is remarkable, that this combination, even when the oxymuriatic acid is perfectly neutralized, has the power of bleaching light or thin goods, though it is much less active in discharging some vegetable colours. Hence this method has certainly a great advantage over all former ones, in the facility and safety of its application, especially to coloured goods, which would be discharged by the contact of either the acid or of lime in an uncombined form. This patent has since been set aside by the decision of a court of law, with what justice we do not pretend to decide. Mr Tennant, however, still retains an exclusive right to a method, secured to him by a subsequent patent, of uniting the oxymuriatic acid with dry quicklime, and thus rendering the bleaching salt portable to any distance in the form of a powder.

EDITOR.‡

[† At present Professor of Chemistry in Carlisle College, Pennsylvania. HEMMEL, jun.]

[‡ As the oxymuriate of lime is found injurious to the fabric of linens and muslins, Mr Davy proposes to substitute the oxymuriate of magnesia, which he says, is perfectly innocuous to the most delicate fabrics. *Id.*]

matters with which cotton and linen manufactures are stained; and that, by a proper use of the alkalies, along with the oxymuriatic acid, these colouring matters could be removed, and the goods rendered white, in a space of time almost instantaneous, when compared with the former method of bleaching.

Upon these discoveries the present improved state of bleaching is founded. And, when the vast extent of the cotton and linen manufactures of Great Britain and Ireland is considered, every improvement in it must be admitted to be of the highest national importance. To exhibit the present state of this art, by giving a succinct statement of the late improvements, is the subject of the following article, which, for the sake of method, shall be arranged under the following chapters, viz: 1. A description of the machinery used in the modern bleachfields. 2. Of the detergent and other substances used. 3. An account of the manner in which these substances are applied.

CHAP. I.

Of the Machinery used in Modern Bleachfields.

The machinery and utensils used in bleaching are various, according to the business done by the bleacher. Where linen or heavy cotton cloths are whitened, and the business is carried on to considerable extent, the machinery is both complicated and expensive. It consists chiefly of a water-wheel sufficiently powerful for giving motion to the wash stocks, dash wheels, squeezers, &c. with any other operations where power is required.

Figures 6. and 7. Plate LV. represent a pair of wash stocks. AA are called the stocks or feet. They are suspended on iron pivots at B, and receive their motion from wipers on the revolving shaft C. The cloth is laid in at D, and, by the alternate strokes of the feet, and the curved form of the turnhead E, the cloth is washed and gradually turned. At the same time, an abundant stream of water rushes on the cloth through holes in the upper part of the turnhead. Wash stocks are much used in Scotland and in Ireland. In the latter country, they are often made with double feet, suspended above and below two turnheads, and wrought with cranks instead of wipers. Wash stocks, properly constructed, make from 24 to 30 strokes per minute.

This mode of washing is now entirely given up in Lancashire, where a preference is given to what are called dash wheels and squeezers. The dash wheels are small water wheels, the inside of which are divided into four compartments, and closed up, only leaving a hole in each compartment for putting in the cloth. There are, besides, smaller openings for the free admission and egress of the water employed in cleansing. The cloth, by the motion of the wheel, is raised up in one part of the revolution of the wheel; while by its own weight it falls in another. This kind of motion is very effectual in washing the cloth, while, at the same time, it does not injure its strength. This plan, however, where the economy of water is an object of any importance, is very objectionable, because the wheel must move at by far too great a velocity to act to advantage as a water wheel.

Fig. 1. Plate LV. represents a dash wheel constructed to receive its motion from a shaft A, connected either with a water wheel or steam engine. The dash wheel, CD, is fixed on a separate axis, and is engaged or disengaged from the rest of the mill work by a very sim-

ple contrivance. On the end of the shaft AB is a face wheel FG, with projecting teeth made to correspond with those of a similar face wheel III. The axis of the dash wheel is made moveable endways; by sliding it forward, the teeth lay hold of one another, and the dash wheel is thus carried round by the mill; by the sliding it backward, the teeth are disengaged, and the dash wheel ceases to move. LM represents the lever for this purpose. NNNN (Fig. 3.) are the holes for introducing the cloth into the four compartments; the partitions are equidistant from the holes. O (Fig. 2.) is the pipe which supplies the water for cleansing the goods. PQ is an open circle in the back of the wheel for introducing the water from the pipe O. The circle has a number of wires set all around to prevent any part of the cloth from escaping through the circle PQ. Near the circumference of the wheel are other holes, through which the water finds its way after passing from the cloth. Dash wheels are made to engage and disengage by various other modes than that which is described above. Circumstances make it necessary to vary these; and a judicious mill-wright will be at no loss how to adapt the mode of throwing the wheel in and out of gear to the rest of the mill-work.

A dash wheel, six feet and a half in diameter, and two feet and a half wide, making twenty-two revolutions per minute, is the most approved size and dimensions. The Plate represents the kind used in Lancashire, and in some parts of Scotland. In the neighbourhood of London, they are a little different in the mode of introducing the water. Instead of having the circumference close boarded, as in Lancashire, they are made of sparred work: The end of the water pipe is flattened so as to make the aperture very wide and narrow; and it is applied near the upper part of the circumference.

After the process of washing by the dash wheel, the water is compressed from the cloth by means of squeezers.

Squeezers consist of a pair of wooden rollers, which, in moving, draw the cloth through between them. The lower roller receives its motion from a mill, and the uppermost is pressed down upon it by means of levers. Till of late, these rollers were fixed in strong wooden frames; but the framing is now generally made of cast iron, which makes a neater and more durable piece of work.

Figures 4. and 5. Plate LV. represent one of these machines having a cast iron framing, as constructed by Mr Parkinson of Manchester. A is the lower roller. B the upper roller. CD a lever which presses upon the brass of the upper roller. FE another lever to increase the power connected with CD. The extremity of F is kept down by a pin. In some cases a weight is used in place of the pin.

The improved mode of bucking was the invention of Mr John Lowrie, a native of Glasgow. It is now practised by many bleachers in Lancashire, some on more perfect plans than others; but we shall give the description of the kind of apparatus most approved of by those whose experience and skill have rendered them the most competent judges.

In Fig. 2. Plate LVI. ABCD is the wooden kieve containing the cloth. CEFD represents the cast-iron boiler. GG the pump. IK the pipe of communication between the kieve and the boiler. This pipe has a valve on each of its extremities; that on the upper extremity, when shut, prevents the ley from running into

the boiler, and is regulated by the attendant by means of the rod and handle IB. The valve at K admits the ley; but, opening inwards, prevents the steam from escaping through the pipe IK. The boiler has a steam tight iron cover IL; and at CD, in the kieve, is a wooden grating, a small distance above the cover of the boiler.

At MNO is a cone and broad plate of metal, in order to spread the ley over the cloth. It is hardly necessary to say, that the boiler has a furnace, as usual for similar purposes.

While the ley is at a low temperature, the pump is worked by the mill or steam engine. When it is sufficiently heated, the elasticity of the steam forces it up through the valves of the pump, when it is disjoined from the mill.

NP is a copper spout, which is removed at the time of taking the cloth out of the kieve.

The boilers used in bleaching are of the common form, having a stopcock at bottom for running off the waste ley. They are commonly made of cast-iron, and are capable of containing from 300 to 600 gallons of water, according to the extent of the business done. In order that the capacity of the boilers may be enlarged, they are formed so as to admit of a crib of wood, strongly hooped, or, what is preferable, of cast iron, to be fixed to the upper extremity of it. In order to keep the goods from the bottom of the boiler, where the heat acts most forcibly, a strong iron ring, covered with netting made of stout rope, is allowed to rest six or eight inches above the bottom of the boiler. Four double ropes are attached to the ring, for withdrawing the goods when sufficiently boiled, which have each an eye for admitting hooks from the running tackle of a crane. Where more boilers than one are employed, the crane is so placed, that, in the range of its sweep, it may withdraw the goods from any of them. For this purpose, the crane turns on spindles at top and bottom: and the goods are raised or lowered at pleasure, by double pulleys and shieves, by means of a cylinder moved by cast-iron wheels.

Before the year 1794, the apparatus used for making the oxymuriatic acid, was so very inconvenient and defective, that the health of the workmen employed was often injured, or at least their situation was rendered very uncomfortable, from the deleterious qualities of the gas. To remedy this defect, Mr Peter Fisher, late of Rutherglen, near Glasgow, in the year 1794, invented an apparatus* admirably calculated for this purpose, which, with very slight alterations, has been almost universally adopted. It consists of a leaden retort A, Fig. 4. Plate LVI. set on a tripod of iron D, into a cast-iron boiler B, built into brick-work, with a furnace and ash pit of the common construction EF. The top of the retort is closed with a leaden cover with screws and nuts, having an iron flange of the same diameter above and below the mouth of the retort, with corresponding nuts and screws. The use of the flanges is to prevent the retort from being compressed out of shape, and thereby preventing its fitting properly. Between the joinings of the mouth of the retort, loose flax, dipt in white lead, ground in oil, is spread equally; and the whole is firmly screwed together. In the top of the cover, a circular hole is made of three inches in diameter, for introducing the materials for making the bleach-

ing liquor, and cleaning out the retort. The hole is fitted with a plug of lead C, which is gently struck into the cover when the apparatus is arranged for working, and is luted with a little soft clay to prevent the escape of gas.

The oxymuriatic gas is conveyed by the lead tube G, which is two inches in diameter, into the intermediate vessel H, set upon a stand as in the figure. This vessel is circular, and is from 12 to 18 inches in diameter, according to the capacity of the other parts of the apparatus; the use of it is to prevent any impurity from descending by the leaden tube I into the receiver K, should the contents of the retort be forced upwards by the effervescence of the materials in it; but this is now seldom the case, since the distillation of the oxymuriatic acid is carried on by the use of the water bath, in place of heated sand.

The receiver K is a vessel of an inverted conical shape made of lead, where the capacity does not exceed 120 gallons, or of wood lined with lead when the quantity of work done is large. It is closely covered at top, and has a hole for introducing water into the receiver at M with a leaden plug. The brass stopcock for drawing off the oxymuriatic acid, is about two inches from the bottom of the receiver, as at N. In some apparatus of this kind, two or three false bottoms, as they are called, LL, made of lead, are laid on brackets of the same metal fixed to the side of the receiver. These false bottoms are pierced full of holes, in order to spread the oxymuriatic gas through the water during the distillation.

CHAP. II.

Of the Detergent and other Substances used in Bleaching.

As it is of importance for the bleacher to be acquainted with the qualities of the substances he uses, and to know the proper methods of ascertaining their purity, in this Chapter we shall briefly point out the manner of arriving at the knowledge of this. The substances used in bleaching are chiefly,

1. Pot and pearl ashes.
2. Soda.
3. Soap.
4. Oxymuriate of potash.
5. Oxymuriate of lime.
6. Manganese.
7. Muriatic acid.
8. Sulphuric acid.

1. Pot and pearl ashes, as they are imported from the United States of America, whence the principal supplies are derived, are of three different qualities: viz. first, second, and third sorts, the casks which contain them being branded by a hot iron with these distinguishing marks. As may naturally be supposed, the first sort is the best, the second next in quality, and the third sort the worst.

But the best potash, as imported, is by no means an alkali free from impurity, it being only comparatively so when its value is estimated with respect to the inferior kinds. It never contains above 70 per cent. of real alkali, but more frequently from 60 to 65 per cent.; the

* The apparatus here described does not differ essentially from that employed by Berthollet, and Pajet Des Charmes.

remainder of the mass consisting of sulphate and muriate of potash, muriate of soda, a portion of uncombined charcoal, carbonic acid, and five or six per cent. of water. As these substances possess no detergent qualities whatever, it is the interest of the bleacher to purchase only those kinds of potash which contain the smallest portion of these adventitious salts. The second sort of potash is often very impure, and the third or lowest quality is frequently designedly mixed with common salt, in order to increase the weight. The same observations are applicable to pearl ashes, which differ from potash only in containing a greater proportion of carbonic acid, and consequently are what is termed a milder alkali.*

When a solution of pot or pearl ashes is made by bleachers, it is customary to ascertain the strength of the solution by the hydrometer, an instrument admirably calculated for this purpose, were these salts always of the same degree of purity. But as this is not the case, we shall point out two methods whereby this may be ascertained with a sufficient degree of accuracy.

1. It is a fact well known to chemists, that the strength of an alkali is in proportion to the quantity of any acid required to saturate it. Thus, if an ounce of one kind of potash requires for saturation a given quantity of sulphuric acid, and an ounce of another kind of potash requires twice that quantity, the latter is twice as strong as the former.

In order, however, to obtain a sufficiently accurate standard of comparison, it will be necessary always to employ an acid of the same strength. This may be effected sufficiently well for ordinary purposes, by diluting the common sulphuric acid of commerce to the same degree by the hydrometer. For example, let the standard consist of one part of acid and five of water. After the mixture has cooled down to the temperature of 60 degrees of Fahrenheit's thermometer, observe the height to which the hydrometer rises, and make this the standard for subsequent trials. The strength of an alkali will now be learned, by observing what quantity of this acid a given quantity of the alkali under trial requires for saturation. For this purpose, put half an ounce of the alkali into a jar with a few ounces of water, and filter the solution; weigh the diluted acid employed before adding it to the alkali; then pour it gradually into the solution till the effervescence ceases, and till the colour of litmus paper, which has been reddened with vinegar, ceases to be restored to blue. When this happens, the point of saturation will be attained. Weigh the bottle, to know how much of the acid has been added, and the loss of the weight of the acid will ascertain the strength of the alkali.

2. Another method recommended by Dr Higgins of Dublin, for ascertaining the purity of potash, is, to take a given quantity of the alkali, and dissolve it in twice its weight of boiling water, stirring the mixture during the solution of the salt; while yet warm, it must be filtered through unsized paper. When all the liquor has pass-

ed through the filter, a very small quantity of cold water is gradually poured on the saline residuum on the filter, in order to wash out the remainder of the alkali. The undissolved salt remaining on the filter, is sulphate of potash, which must be carefully taken off, dried and weighed, in order to ascertain its quantity. To determine whether any common salt is contained in the alkali, which has been filtered, evaporate the clear solution a little in a sand bath, and set it in a cool place for 24 hours; at the end of which time, any common salt it may contain will be found crystallized in the form of regular cubes at the bottom of the vessel. The sulphate of potash and common salt being dried, weighed, and deducted from the weight of the crude alkali employed, will give the precise weight of the pure alkali it contains.

11. Pure carbonate of soda, or the mineral alkali, so much resembles the vegetable alkali, when used as an agent in bleaching, that little difference is observable in its effects when the strength of the alkaline leys and every other circumstance are the same. The high price at which soda has hitherto sold, has prevented its being generally used at the bleachfield; but since more economical processes are adopted in the manufacture of it, and since it is made in a greater degree of purity, its introduction into the bleachfield will naturally follow. It is admirably calculated, as a detergent, for the finishing of the finer fabric of muslin; it being ascertained beyond doubt, that 6 ounces of pure carbonate of soda, together with 10 ounces of soap, produce effects in bleaching equal to 1½ pounds of soap, when used by itself.

2d, Barilla, as imported from Alicant in Spain, is in large masses, of a dark gray colour. It usually contains from 20 to 24 *per cent.* of pure mineral alkali, and never above 33 *per cent.* when in a state of the greatest purity. The remainder of the mass usually consists of sulphate and sulphite of soda, with a large proportion of charcoal and common salt.

The best method of extracting the soda from barilla, is to pound it, and fill a large wooden vat with it, the bottom of which has been previously covered with straw, to act as a filter; the vat is then filled with cold water, which is allowed to remain for some time to dissolve the salt. When sufficiently strong for use, the solution is run off at the bottom of the vessel by a stop-cock, by which means it is freed from the charcoal and other impurities. Fresh water is again poured on the barilla, until the whole of the salt is dissolved. By this operation the soda is extracted, which being a very soluble salt, is easily dissolved by the water; but, at the same time, the common salt, which is equally soluble, together with a portion of the sulphate of soda, is also dissolved, which contaminate the solution, and have no effect as detergents. On this account, pure soda is certainly preferable for bleaching, (when it is not too high priced,) as it contains none of the foreign salts contained in barilla, which retard in place of promoting the process of bleaching. The bleachers in Ireland formerly used large quantities of barilla, but its use is now almost universally given up, potash being substituted in its stead.

3d, Kelp would be unworthy of notice, were it not that it is still recommended by some as a detergent in bleaching.

As at present manufactured, kelp is very inferior in this respect: The very best Scotch kelp never contains above 7 or 8 *per cent.* of mineral alkali, but more commonly from 3 to 5 *per cent.* Considering the other im-

* The above observation is not correct. Potash is merely the lixivium evaporated to dryness. Pearl-ash is the same potash heated in a reverberatory furnace, by which the carbonaceous matter is consumed, and the moisture, with a considerable part of the carbonic acid, is expelled. Hence, potash is a carbonate, pearl-ash a sub-carbonate of potash. HEMMEL, JUN.

pure substances contained in kelp, it is at present unworthy of attention. But there is no doubt, that if proper methods were adopted for the manufacturing of it properly, it may be very much improved in quality. In the present rude manner in which it is made, the marine plants called *Fucus Serratus* and *Fucus Vesiculosus* of Linnæus, being cut at midsummer, and dried by the sun and air, are burnt in holes made in the sea beach: when a large portion of it is burnt together, part of the salt fused by the strong heat combines with sand, and other earthy matters, and forms an imperfect glass. In a furnace properly constructed, with a graduated heat, we have known kelp made of a quality far superior to the very best of that which is made by the common process.

It has been suggested, that were the sea plants, from which the kelp is made, previously washed in fresh water before they are dried, they would thereby be freed from a large portion of the marine acid adhering to them, which remains undecomposed during the burning of the plant when it is converted into kelp. This theory supposes, that the plant, during the progress of its growth, has the power of decomposing the sea-water, and retaining soda as one of its component parts: and that if this be the case, and if the combustion of the plant were properly conducted, a salt nearly equal in value to barilla would be the product. These facts may be easily proved by those who have skill to ascertain, and opportunity to investigate, a matter which is of considerable national importance.

In order to ascertain the quantity of real alkali contained in the different detergent salts used in bleaching, M. Descroizilles, sen. employed the method before mentioned, by saturating a given quantity of the alkaline salt with diluted sulphuric acid, the specific gravity of which was always the same.

After many thousand trials during the course of 25 years practice, the following are the mean results:

	Real Alkali in 100 Parts.	
Best American pearl ashes,	60	73
Caustic ditto pot ashes in reddish lumps,	60	63
Second ditto ditto in gray lumps,	50	55
Second ditto pearl ashes,	50	55
White Russian pearl ashes,	52	58
White Dantzic ditto,	45	52
Alicant barilla,	20	33
Inferior kinds of barilla,	10	15
Natron,	20	30
Salt of tartar of the shops,		72

To these may be added the following from Mr Kirwan's tables of the composition of salts:

	Alkali.	Acid.	Water.
Crystallised carbonate of potash,	41	43	16
Ditto carbonate of soda,	21½	14½	64
Ditto ditto desiccated,	60	40	

Hence it appears evident, of what importance it is to bleachers, and others who use alkalis in any quantity, to have it in their power to ascertain the quantity of pure salt contained in them; as, by a proper knowledge of this, great saving may be made by them in the course of their business.

III. Soap is an article so well known, that it requires no particular description. It is sold of three different kinds, viz. brown, white, and soft soaps. It is the two

latter kinds which are chiefly used in bleaching; the former being commonly sold for household washing in some parts of Britain.

IV. Of all the agents used in bleaching, there is none of them which ranks higher for giving facility and dispatch to the various operations than the oxymuriatic acid.

We might even at this moment have been unacquainted with the cause of the destruction of the colouring matter of vegetable substances, if the discovery of this acid, and its effects on colouring matter, had not pointed it out to us. For this discovery, and its inestimable advantages, the arts are indebted to the celebrated Scheele. While employed in making experiments on manganese, about the year 1774, he noticed its powers in rendering vegetable substances colourless, more as a matter of curiosity than of use. Having communicated his observations to Berthollet, in France, about the year 1786, the latter lost no time in applying the properties of this curious and interesting substance to the most important practical purposes. His application of it to the bleaching of cotton and linen cloth proving successful, he published the result of his experiments in the year 1789. The new method of bleaching was quickly and successfully introduced into the manufactories of Rouen, Valenciennes, and Courtray; and soon after into those of Manchester and Glasgow; and it has since been generally adopted in Great Britain, Ireland, France, and Germany. The advantages which result from this method of bleaching, in every season of the year, can be best appreciated by commercial people who experience its beneficial effects in many ways, but particularly in the quick circulation of their capitals.

Great difficulties at first impeded its progress, arising chiefly from prejudice, as well as from the ignorance of the bleachers in chemical processes. These obstacles were however soon removed by the assistance of several eminent chemists at Glasgow and Manchester, particularly Messrs Watt, Henry, and Cooper. See p. 554, *Note*.

Mr Berthollet's process for forming the oxymuriatic acid, consisted in distilling one part of the black oxide of manganese with two parts of muriatic acid, in a glass retort; the product of the distillation was received in glass bottles, properly applied, when the quantity was small, or into a receiver lined with lead when the quantity was larger.

From the volatility of the oxygen as united with the muriatic acid, when simply diffused in water, with which it has a very slight affinity; and, consequently, its unequal action on the goods which were immersed in it for the purpose of being whitened, and its discharging those colours which were woven into the goods intended to remain permanent; as well as the suffocating vapours arising from it proving hurtful to the health of the workmen employed, it soon became evident, that the application of it in an extensive manner would be impracticable if these difficulties were not more or less removed. Various attempts were made to effect this; and since it has been accomplished, a number of persons have put in their claims as the inventors of so advantageous an improvement. Mr Higgins of Dublin and Mr Berthollet had both combined the oxymuriatic acid with potash, so early as the year 1788. The knowledge of the latter's having done so, and that the acid was thereby deprived of its offensive smell, induced the bleachers at Javelle, in France, to add a solution of caustic

potash. Hence the oxymuriatic acid combined with an alkali, is usually known by the name of the Javelle liquor.

Notwithstanding this evident improvement, it was still generally maintained by chemists, that the oxymuriatic acid, united simply with water, possessed greater bleaching power than that which is combined with caustic alkali; but this was contradicted by the practical bleachers, whose experience taught them, that though the acid, thus combined with an alkali, whitened with somewhat less rapidity, it had the advantage of retaining the gas much longer in open vessels, and of preserving fixed dyed colours, such as the Turkey or Adrianopic red. These facts are now so fully established, that although several attempts have been made, since the year 1796, again to introduce the oxymuriatic acid, diffused simply in water, into air tight vessels, to prevent its offensive smell, yet, from a conviction of its absurdity, it has been adopted only by a few.

In order to produce the oxymuriatic acid, bleachers follow different methods to obtain a liquor which they suppose possesses the highest bleaching powers. In one point they generally agree, which is, in giving a superabundance of the materials employed, by which they are certain of procuring a liquor which possesses high bleaching powers. One of the most common proportions of materials employed for making this acid, is to take equal parts, by weight, of common salt and manganese, which are intimately mixed together. Some bleachers moisten the mixture with water, to the consistence of a thick paste, so that the dissolved salt may incorporate more intimately with the manganese. An equal weight of sulphuric acid is taken as of the other materials, which is diluted with its bulk of water, and allowed to cool before being poured into the retort on the combined salt and manganese. The charge for the distillation thus consists of equal parts of salt, manganese, and sulphuric acid, diluted with an equal bulk of water.

In the above proportions of the materials, it is evident, that the quantity of sulphuric acid employed is more than sufficient for expelling the muriatic acid from the salt; two thirds of the former acid being enough to disengage the latter at a moderately high temperature. Hence, when equal parts of salt, manganese, and diluted sulphuric acid, are used in the distillation of the oxymuriatic acid, the residuum taken from the retort is uniformly found to be supersulphate of soda combined with manganese. The quantity of manganese used is also too great, and much of this substance is wasted, no more being necessary than is sufficient fully to oxygenise the muriatic acid during the distillation.

At the same time, it is proper to remark, that the proportion of manganese must be subject to variation according to its quality.

Mr Rupp of Manchester (*Trans. of the Lit. and Phil. Soc. of Manchester*, vol. v.) recommends, manganese 3 parts, common salt 8, sulphuric acid 5, water 12. The bleachers in the neighbourhood of Glasgow commonly use equal parts of salt, manganese, sulphuric acid, and water, as mentioned above. In Ireland, the common proportions are said to be, manganese 6 parts, common salt 6, sulphuric acid 5, water 5. In France and Germany, we understand, they vary little from the following: manganese 20 parts, common salt 64, sulphuric acid 44, water 54.

Besides the above methods of making the oxymuriatic

acid, that which was originally introduced by Mr Berthollet has again been used by several bleachers, on account of the high price of potash. It consists of introducing one part of oxide of manganese into the retort, on which is poured two parts of muriatic acid, of the specific gravity of 1200, which is diluted with its bulk of water.

The reason given by those who have again resorted to the latter process for making this acid, is, that one-half of the quantity of alkali is sufficient for neutralizing it in the receiver, because the oxymuriatic acid gas is presented in a pure state without any mixture of sulphureous acid gas, which they suppose is always produced by a part of the sulphuric acid being decomposed in the retort by the impurities mixed with the oxide of manganese; and that, in consequence, one-half of the alkaline lixivium is sufficient, no more alkali being necessary than a sufficiency to retain the oxymuriatic acid gas in a proper state of neutralization for the purposes of bleaching. Whatever of theory may be in these inferences, it is certain, that bleaching liquor made in this manner possesses power equal, if not superior, to any in use, for rendering goods white expeditiously.

We shall now describe the preparation of the oxymuriatic acid combined with potash, as conducted in the apparatus invented by Mr Fisher. See Plate LVI Fig. 4.

Supposing the receiver K to contain 120 gallons English wine measure, it is filled at the hole M with a solution of caustic potash of the specific gravity of 1015; the lead stopper is then replaced. Twenty-one lbs. of common salt being intimately mixed with fourteen lbs. of the black oxide of manganese, the mixture is moistened with water, and wrought together until it is of the consistence of moist dough. By this means, the salt, in a state of solution, unites more intimately with the manganese. The top of the retort being removed, the salt and manganese are put into it; the cover is then replaced, and firmly screwed on its place.

Into 16lbs. of sulphuric acid pour gradually the same weight of water, and allow the mixture to cool. One half of the diluted acid is poured, by a lead funnel, into the retort by the hole at C, which is then closed by the lead plug to prevent the escape of the oxymuriatic gas which is instantly disengaged, after which a violent agitation is heard in the receiver K. The distillation is usually begun in the evening, and the workman, after seeing the operation going properly forward, leaves it to work of itself. In the morning, the distillation having abated, the remainder of the diluted sulphuric acid is poured into the retort, when a fresh disengagement of the gas takes place. As soon as it is observed to slacken, a fire is put into the furnace in order to heat the boiler B, which is filled with water, into which chaff or any similar light substance is put to prevent the evaporation of the water. By the increased heat of the water, the distillation goes forward with renewed vigour; and the fire is continued until no more gas is disengaged, which is known by the bubbling noise in the receiver being no longer heard. The oxymuriatic acid combined with potash may now be drawn off by the stop-cock N from the receiver for use.

In the above process, the sulphuric acid having a greater affinity for the soda contained in the common salt than that which the muriatic acid has, the latter is disengaged from the soda, and, acting on the manganese, it deprives it of its oxygen, which now existing in the state of oxymuriatic acid gas, by its expansive force is

impelled forward through the tubes G and I into the receiver K, where it is absorbed by the caustic alkaline solution.

V. No farther improvements seem to have taken place in the combination of this acid with any other substance than the alkalis until the year 1798, when Mr Charles Tennant of Glasgow, by a well conducted series of experiments, shewed, that it was capable of being united with what are called the alkaline earths, such as barytes, strontites, and lime. Lime being most readily procured, after a number of trials he found, that, by mechanical agitation, and in consequence of the suspension of the finer particles of the lime in water, it readily united with the oxymuriatic acid gas, and was thereby completely dissolved. When, therefore, a sufficient quantity of finely pulverised quicklime is put into the receiver K in place of potash, and mechanically agitated during the distillation of the oxymuriatic acid, it will be found that it is entirely dissolved, and forms a pure and transparent solution of oxymuriate of lime, possessing the same power of retaining the gas as the alkalis do.

Mr Tennant has since carried this improvement to a greater degree of perfection, by combining the oxymuriatic acid with quicklime in the dry way, and thus rendering it portable to any distance at a small expence. For this further improvement he justly received another patent, which secures him the exclusive right of this valuable manufacture. This discovery is of great importance, as, by means of so common and cheap a substance as lime, great savings are made by the bleacher in the expence of alkali; and this improvement may not improperly be called a new era in the history of bleaching.*

For use, the concrete oxymuriate of lime is diffused in water by agitation; the insoluble matter contained in the lime is allowed to subside until the liquor is transparent. When drawn off for use, it is further diluted with water before the goods are immersed in it, in order to be whitened. (*)

VI. The oxide of manganese, when of a good quality, is of a black shining colour; when combined with oxygen at a maximum, it contains 44 parts of the metal with 66 parts of oxygen; but as taken from the mines which contain it, it is never found so pure. The principal defect of manganese arises from its being united with chalk, or ores of iron; and when any of these are mixed in quantity with it, its effect is proportionably weakened in making bleaching liquor. The presence of carbonate of lime may be discovered in manganese, by pouring on a portion of this substance nitric acid diluted with eight or ten parts of water. If the manganese be good, no effervescence will ensue, nor will the acid dissolve anything; but if carbonate of lime be present, it will be ta-

ken up by the acid. To the solution add a sufficient quantity of carbonate of potash to precipitate the lime. Its weight will show how much chalk the manganese under examination contained.

The adulteration of manganese when it is mixed with the ores of iron is less easily discovered. But if the iron be in such a state of oxidation as to be soluble in muriatic acid, the following process may discover it: Dissolve a portion of the manganese in strong muriatic acid, with the assistance of heat; dilute the solution largely with rain-water, and add a solution of crystallized carbonate of potash. The manganese will remain suspended by the excess of carbonic acid, but the iron will be precipitated in the state of a coloured oxide, on mixing the two solutions. From an observation of Klaproth's, (*Essays*, i. p. 572.) it appears that oxides of iron are separable by nitrous acid, with the addition of sugar, which takes up the manganese only.

VII. Sulphuric acid, or oil of vitriol, as it is commonly called, when pure, is a transparent, colourless fluid, slightly viscid, and without smell. The specific gravity of the sulphuric acid of commerce is generally 1850, or almost twice the weight of distilled water. The manufacture of it is now carried on to such extent in Great Britain, that any further description of a substance so well known is unnecessary. The only substances with which it is ever adulterated are lead, and supersulphate of potash. A small portion of lead is taken up during its formation, in chambers of that metal, and its subsequent concentration in boilers. On this account, a white precipitate is often found in the bottom of the bottles containing it, which is sulphate of lead. After the combustion of the sulphur and nitre in the manufacture of sulphuric acid, supersulphate of potash is left as a residuum, by the affinity of the potash contained in the nitre with the sulphuric acid. Some manufacturers add a strong solution of this salt to the water which is put into the lead chambers where the sulphuric acid is formed. Now, in proportion to the quantity of potash contained in this solution, in so far is the specific gravity increased, and, in consequence, the sulphuric acid is rendered ineffectual for answering the purposes of bleaching.

This adulteration is carried so far as frequently to leave only four-fifths of pure acid. Hence it ought to be the bleacher's study to purchase what contains only pure sulphuric acid.

VIII. The muriatic acid of commerce has generally a slightly yellowish tinge, which proceeds partly from the impurities contained in the common salt from which it is made, and partly from its being distilled in iron retorts. When distilled in glass vessels from pure salt, the muriatic acid is perfectly colourless, and its specific gravity is about 1170.

CHAP. III.

An Account of the Manner in which these Substances are applied.

The common operations of bleaching consist of

Steeping,
Bucking,
Boiling,
Immersion in the oxymuriatic acid.
Souring, washing, &c.

(*) The bleaching with oxymuriate of lime has been used in several of the manufacturing establishments in the United States. The oxymuriatic acid itself has been employed; but the preparation of the oxymuriate answers a better purpose. Messrs Craig and Marquandant have lately introduced this bleaching salt into their manufactory. I made them a portion, which they found to answer remarkably well. They are now erecting apparatus for the purpose, which will supercede their present plan, of bleaching by steam. CUTBUSH.

* Vide Note p. 554.

SECT. I. *On Steeping.*

In the preparation of yarns for weaving, whether composed of flax or cotton, it is necessary that the weaver employ some gelatinous substance to give the threads the requisite adhesion to stand the operation of weaving. This substance is commonly made of wheaten flour, boiled in water to the consistence of pap, which is applied to the threads with a brush. This is the principal extraneous matter upon the goods, which it is the business of the bleacher to remove. To accomplish this, the linens, after being properly assorted, are washed in the wash stocks (Plate LV. Fig. 6.) for some hours, in order to free them from loose stuff which may be attached to them. They are then put into a large circular vat, made of fir-deal boards, called technically a kieve, into which they are laid regularly one above another, without being too much compressed. After the goods are disposed in the kieve, it is filled with alkaline ley, at a blood-heat, which has been already used in bucking or boiling former parcels. A piece of wood, in the form of a cross, is then fixed above the goods, in order to keep them below the liquid.

In a few hours an intestine motion is observable, and an increase of temperature takes place; the liquid swells; bubbles of air rise to the surface; and a thick scum is thrown up. This fermentation continues from twelve to eighteen hours, according to the state of the weather. So soon as it is observed that it has ceased, the goods must be instantly withdrawn from the kieve, and again carried to the wash stocks, or to the dash wheel, in order to be cleared from the loosened filth. Should the goods be left too long in the steep, they are liable to considerable damage; as, after the acetous fermentation ceases, the putrid fermentation begins, and the coloured matter, in place of being loosened from the goods, is fixed in them; and, at the same time, the dissolution of the vegetable fibre of the cloth is begun, and were they to remain too long in this state they would absolutely rot. It is therefore the bleacher's care to guard against so serious an accident.

SECT. II. *On Bucking.*

This is one of the most important operations in the bleaching of linen goods. There are several methods whereby this process is carried on, but of these we shall only select two, distinguishing them as the old and new methods of bucking. In the former way, the linens having been steeped in the alkaline ley, as before described, and afterwards well washed, are regularly arranged in a large wooden vat, or kieve; a boiler of sufficient capacity is then filled with caustic alkaline ley, which is heated to the temperature of blood. The boiler is then emptied by a stopcock upon the linens in the kieve, until they are covered with the liquor. After having remained on the cloth for some time, it is run off by a stopcock at the bottom of the kieve, into an iron boiler sunk in the ground, from whence it is raised into the boiler by a pump. The heat is now raised to a higher temperature, and the ley again run upon the goods in the kieve; from whence it is returned into the boiler, as before described: and these operations are continued, always increasing the heat, until the alkaline ley is completely saturated with the colouring matter taken from the cloth, which is known by its having acquired a completely offensive smell, and losing its causticity.

When we consider the effect which heated liquids have upon coloured vegetable matter, we shall see the propriety of the temperature of the alkaline ley being gradually increased. Thus, when vegetable substances are hastily plunged into boiling liquids, the colouring matter, in place of being extracted, is by this high temperature fixed into them. It is on this principle which a cook acts in the culinary art, when the green colour of vegetables is intended to be preserved: in place of putting them into water when cold, they are kept back until the water is boiling; because it is well known, that, in the former case, the green colour would be entirely extracted, whereas, when the vegetables are not infused until the water is boiling, the colour is completely preserved, or fixed. On the same principle, when the temperature of the alkaline ley is gradually raised, the extractive and colouring matter is more effectually taken from the cloth; and the case is reversed when the ley is applied at the boiling temperature, so much so, that linen which has been so unfortunate as to meet with this treatment, can never be brought to a good white.

When the alkaline ley is saturated with colouring matter, it is run off, as unfit for further use in this operation. But were the linens to be instantly taken out of the kieve, and carried to be washed in the dash-wheel while hot, a certain portion of the colouring matter would be again fixed into them, which is extremely difficult to eradicate. In order to prevent this, the most approved bleachers run warm water upon the cloth so soon as the impure ley is run off; this combines with, and carries off part of the remaining impurities; a stream of water is then allowed to run on the cloth in the kieve, until it comes off almost transparent. The linens are now taken to the wash-stocks, or to the dash-wheel, to be further cleaned, with the greatest safety.

The process of bucking was long carried on in this manner without any improvement, until Mr John Lounrie, as before narrated, introduced an apparatus admirably calculated for conducting this operation on the large scale, which being in some measure self operative, much labour, as well as a considerable quantity of alkali, is saved.

The boiler (Plate LVI. Fig. 2.) being filled with caustic alkaline ley, and the linens being properly arranged in the wooden kieve above it, the handle of the pump GG is set in motion by the machinery: the ley now flows through the pipe N by the working of the pump, and falling on the broad plate of metal MO, it is spread in a perpetual current on the cloth, while the valve K opening inwards, admits the ley to return into the boiler. Immediately on the pump being set to work, a fire is put to the boiler, by which the ley being gradually heated, the linens receive the benefit of the regular increase of temperature, and the colouring matter from the cloth is thereby more effectually removed. When the ley begins to boil, the handle of the pump is detached from the machinery of the water wheel, and by the ley being completely confined in the close boiler, it is forced up the pump, and falls in a perpetual stream through the pipe N upon the linens in the kieve ABCD.

The efficacy of this manner of conducting the bucking process must be evident at first sight: while the heat is gradually increased, a current of fresh ley is constantly presented to different surfaces of the goods for saturation, thereby rendering it more active in cleansing

BLEACHING.

them. Besides, the manner in which the apparatus is first wrought by the water wheel, or steam engine, and its self-operating power afterwards, puts it completely out of the power of servants to slight the work, independent of the great saving of alkali, which, in most cases where it has been applied, amounts to from one-fourth to one-third of the quantity formerly used.

SECT. III. *On Boiling.*

In the bleaching of linen cloth, boiling is only used when the goods are nearly white, with pearl ashes alone, or with pearl ashes along with soap towards the end of the whitening process: all that is necessary in this operation, is to keep the goods completely under the liquid, so that it may act uniformly upon them. In no case is the boiling carried on in a violent manner, but with a gentle simmering heat. The boilers are made of cast iron, of the common construction, with a large stopcock at bottom, in order to empty it of the waste ley.

SECT. IV. *Immersion in the Oxymuriate of Potash.*

According to the doctrine of modern chemists, the oxymuriatic acid, in consequence of yielding up its oxygen to the colouring matter of vegetables, thereby deprives them of colour, and by this means they are further prepared for alkaline substances acting upon them, and fitting them for the reception of oxygen in subsequent immersions. We have already described the method of preparing the oxymuriatic acid with potash at some length, and have now only to remark, that the common way of diluting it for use, is by adding it in sufficient quantity to pure water, until the specific gravity of the mixture is 1005. The linens, after being clean washed, are steeped in it for twelve hours, then drained, and washed for being further bucked or boiled.

SECT. V. *On Souring.*

Souring is in general the last or finishing process in bleaching, as afterwards the linens are only further washed in spring water, in order to their being blued and made up for the market.

In preparing the sour, into a large fir tub, lined with lead, as much sulphuric acid is added to water as will give it the acidity of strong vinegar. The acid and water must be well mixed together before immersing the linens, which are generally steeped in it for twelve hours, then drained, and washed in pure water. The operation of washing must be paid particular attention to after this

process; were any of the acid to remain in the goods, and to be dried into them, they would infallibly rot, although the acid has no such effect upon them while they are kept wet.

What effect souring has in bleaching, neither the practical bleacher nor the chemist have attempted to determine. It is certain, that, from frequent use, it completely loses its acidity, and remains an inert substance, similar to a neutral salt. Some suppose that it is saturated with the remaining alkali which has not been completely washed from the goods; with iron, which is said to be a component part of all vegetable substances; or with earth, which is likewise said to be contained in them. Whatever may be in these conjectures, it is certain, that when linens are soured about the middle of the bleaching process, it has a considerable effect in hastening forward the goods to a complete white, and, in consequence, early souring has been adopted by the best practical bleachers.

Having made these preliminary observations with regard to the method of applying the various articles used in bleaching linen cloth, we shall now bring the whole into one point of view, by detailing the connection of these processes, as carried on at a bleachfield which has uniformly been successful in returning the cloth of a good white, and otherwise giving satisfaction to their employers; and we shall only previously remark, that we by no means hold it up as the best process which may be employed; as every experienced bleacher knows, that processes must be varied, not only according to existing circumstances, but also according to the nature of the linens operated upon.

In order to avoid repetition, where washing is mentioned, it must always be understood that the linen is taken to the wash stocks, or dash wheel, and washed well in them for some hours. This part of the work can never be overdone; and on its being properly executed between every part of the bucking, boiling, steeping in the oxymuriatic acid, and souring, not a little of the success of bleaching depends. By exposure is meant, that the linen cloth is taken and spread upon the bleach-green for four, six, or eight days, according as the routine of business calls for the return of the cloth, in order to undergo further operations.

"A parcel of goods consists of 360 pieces of those linens which are called Britannias. Each piece is 35 yards long, and they weigh on an average 10 lbs. each: the weight of the parcel is, in consequence, about 3600 pounds avoirdupois weight. The linens are first washed, and then steeped in waste alkaline ley, as formerly described under these processes; they then undergo the following operations:

- 1st, Bucked with 60 ℥ pearl ashes, washed, exposed on the field.
- 2d, Ditto . . . 80 . . . do. . . . do. . . . do.
- 3d, Ditto . . . 90 . potashes, . . . do. . . do. . . . do.
- 4th, Ditto . . . 80 . . . do. . . . do. . . . do.
- 5th, Ditto . . . 80 . . . do. . . . do. . . . do.
- 6th, Ditto . . . 50 . . . do. . . . do. . . . do.
- 7th, Ditto . . . 70 . . . do. . . . do. . . . do.
- 8th, Ditto . . . 70 . . . do. . . . do. . . . do.
- 9th, Soured one night in dilute sulphuric acid, washed.
- 10th, Bucked with 50 lb pearl ashes, washed, exposed on the field.
- 11th, Immersed in the oxymuriate of potash 12 hours.
- 12th, Boiled with 30 ℥ pearl ashes, washed, exposed on the field.
- 13th, Ditto . . . 30 . . . do. . . . do. . . . do.
- 14th, Soured, washed.

The linens are then taken to the rubbing board, and well rubbed with a strong lather of black soap, after which they are well washed through pure spring water. At this period they are carefully examined, and those which are fully bleached are laid aside to be blued and made up for the market; while those which are not fully white, are returned to be boiled and steeped in the oxymuriate of potash, and soured, until they are fully white."

By the above process, 690 pounds weight of alkali is taken to bleach 360 pieces of linen, each piece consisting of 35 yards in length; so that the expenditure of alkali would be somewhat less than 2 lb for each piece, were it not that some part of the linens are not fully whitened, as above noted. Two pounds of alkali may therefore be stated as the average quantity employed for bleaching each piece of goods.

The method of bleaching linens in Ireland is similar to the foregoing; any alteration in the process depending on the judgment of the bleacher in increasing or diminishing the quantity of alkali used. But it is common at most bleachfields to steep the linens in the oxymuriate of potash, or lime, at an early stage of the process, or after the goods have undergone the fifth or sixth operation of bucking. By this means, those parts of the flax which are most difficult to bleach are more easily acted upon by the alkali; and, as before noticed, souring early in weak diluted sulphuric acid assists greatly in forwarding the whitening of the linens. Mr Grimshaw, calico printer near Belfast, was the first who recommended early souring, which has since been very generally adopted.

CHAP. IV.

Bleaching for Calico Printing.

In bleaching linen and cotton cloth, for the purpose of being stained with different colours, in the process of calico printing, a pure white is not so much sought for, as that the goods are what is technically called well rooted; that is, that the colouring matter and vegetable oil is fully extracted from them. This is attained chiefly by the linens being bucked and boiled in a solution of alkali, rendered moderately caustic by quicklime, in order to preserve the fabric of the cloth from being too much reduced. The alkaline solution must be well settled, and transparent as water; because, if the lime remains either in solution or suspension in the smallest proportion, it is apt to be precipitated into the fabric of the cloth, and destroy the purity of those parts intended to be white. Linen cloth requires to be bucked and boiled from ten to twelve times in the alkaline solution; being well washed and exposed on the bleachgreen between each operation. It is soured at the end of the sixth boiling; and again soured at the end of this process, when the goods are supposed fully bleached for printing.

To ascertain whether the cloth is fit for printing, a small stripe is torn from the end of one of the pieces, and printed with one of the mordants used in the fixing of the dye. After that the mordant has remained a sufficient time in the cloth, it is rinsed in pure water to carry off the superfluous parts of the mordant, and then immersed into a copper pan in cold water, which contains a little madder; the heat is gradually increased, while the cloth is alternately raised and lowered by a

bit of stick in the decoction of madder, until the colour is dyed to the shade required. At this period, if the cloth is properly bleached, the place stained with the mordant will alone have attracted the colouring matter of the madder; while the rest of the rag remains white. But should the part intended for white be stained a dirty light red, the cloth is not fully bleached, and it must again be boiled in the solution of alkali.

Cotton cloth intended for calico printing is more easily bleached than linen cloth; five, or at most six boilings in the alkaline solution, being all that is requisite for making a good white. One pound of potashes is fully sufficient to bleach a piece of calico of 21 square yards. This gives about three ounces of potash to each piece for every time they are boiled. Between every part of the boiling process, the calicoes are washed and exposed on the bleachgreen, the same as linen cloth; and soured, at the end of the process, in the same manner. In order to ascertain whether they are fully bleached for printing, the same method is followed as that which is already described for the trial of linen cloth.

In bleaching both kinds for printing, it is not customary to immerse them in the oxymuriatic solutions; except in the winter months, when a good white is not so easily obtained, by the action of the sun and air. Neither are the goods watered artificially when spread on the bleachgreen; but they are (after being well washed) allowed to lie exposed to all the vicissitudes of the season, until the common routine of business calls for their return to undergo farther operations. This process is commonly called dry bleaching, in contradistinction to that in which the goods are artificially wetted when exposed on the field.

After linen or cotton cloth is printed and dyed, a certain dulness of colour attaches itself to the parts intended to remain white; arising partly from the imperfection of the bleaching, but more frequently from a part of the mordant, which has been printed on the cloth, being loosened by the increased temperature of the water bath. This unites with the decoction of madder or other colouring matter used in the bath, and is precipitated on the parts intended to remain a pure white. To remove this partial stain in an easy manner, without long exposure upon the bleachgreen, has long been much wanted by calico printers.

In order to attain this, various methods have been resorted to without effect, arising partly from the imperfection of the substances employed. Steeping printed goods after being dyed, in the oxymuriate of lime, not only changes all the colours, and renders them of a duller hue; but also particles of the lime attach themselves so intimately to the cloth, that it acts as a discharge, and effaces the colours altogether. Although a dilute solution of the oxymuriate of potash does not act in so severe a manner as the oxymuriate of lime, yet it operates strongly as an alterative to most colours; changing the red colour to pink, and the purple and lilac are turned to bluish shades of the same colour; besides, the action of the alkali scourges the whole colours, by reducing their intensity and brilliancy. In consequence of these defects, both these substances are unfit for producing a good white on printed goods; without at the same time acting as an alterative, in completely changing the shade of colour wanted.

In searching for a substance which possesses none of these pernicious qualities, we have found, that the oxy-

muriate of magnesia in every respect answers in the most complete manner, not only for clearing the white ground of the goods, but also in preserving the colours of the same shade which they were originally.

Of all the earths which are partially soluble in water, magnesia possesses the property of changing colours least; the alteration made by it on paper stained with litmus being scarcely perceptible. It is, therefore, peculiarly fitted, when united with oxygen, for the purpose of clearing the stain from the white of printed goods.

In making this preparation, the magnesian earth must be previously broken in water, as fine as possible, in the manner of starch. It is then introduced into the receiver K of the apparatus for making the oxymuriatic acid. (See Plate LVI, fig. 4.) Into the retort A one part of good manganese is introduced, on which is poured two parts of muriatic acid, of the specific gravity of 1200, diluted with its bulk of water; the distillation instantly commences, and the magnesia is dissolved by the oxymuriatic acid. In order to keep the magnesia in suspension, it is necessary to agitate the liquor in the receiver occasionally by a staff similar to a churn staff, which is placed in the receiver, the handle coming up through the centre of the cover.

When the magnesia is dissolved, and the impurities which it may contain have subsided, it is drawn off for use. For this purpose, a clean copper is filled with pure water, and the heat is raised to about 160 or 170 degrees of Fahrenheit. So much of the oxymuriate of magnesia is then added as will give to the water in the copper a sensible taste of the salt. As soon as it is introduced, the whole must be quickly mixed together by a clean broom. The printed goods, having been previously slightly braned, are then quickly run over the wince into the copper; continuing to run them over the wince until the white is sufficiently clear. This operation takes only a few minutes. The goods are then carried to be streamed in pure water, to prevent the further action of the oxygen on the colours. By the addition of a little more of the oxymuriate of magnesia, fresh parcels of goods may be entered into the copper for clearing, and the process may be thereby continued for a whole day; after which the contents are run off from the boiler.

CHAP. V.

On Bleaching Muslin.

In the bleaching of the coarser kinds of Muslin, such as the fabric of goods called *Jaconet*, after they have been steeped and washed, they are first boiled in a weak solution of pot and pearl ashes; after being again washed, they are twice boiled in soap alone, and then soured in very dilute sulphuric acid. Being washed from the sour, they are again boiled in soap, washed, and then immersed in the oxymuriate of potash. The boiling in soap, and steeping in the oxymuriate, is now repeated, until the muslin is a pure white. They are then soured and washed in pure spring water.

In bleaching the finer fabrics of muslin, such as those kinds called *Mull Mull* and *Book*, nearly the same process is followed as the above for bleaching of *Jaconet*;

only that, on account of the fineness of the fabric, no pearl ashes are used in boiling, but soap alone. Otherwise, they are treated in the same manner, in being alternately washed, boiled and steeped in the oxymuriate of potash; and when fully white, they are soured in dilute sulphuric acid.

In the bleaching of cotton cloth, where fixed colours* are previously dyed in the yarn before it is wove into cloth, great care is necessary. Before it was customary to introduce caustic alkali into the receiver of the apparatus for making the oxymuriate of potash, the most complete uncertainty occurred with the bleacher in his attempts to bleach cotton goods wherein the most fixed colours were wove. Sometimes the colours were in tolerable preservation when the oxymuriatic acid was used in moderation; at other times, the colours were almost entirely extracted from this acid being used too strong. At last it was discovered, that when a considerable quantity of the alkali was introduced into the receiver, for the neutralizing of the oxymuriatic acid, that the fixed or permanent colours, which were immersed into it, were by no means injured. On this principle, cotton goods of the kind called *Pulicates*, into which fixed colours are wove, and which have thoroughly to undergo the whole process of bleaching, the colours are more brilliant than in those goods of the same kind, which are wove along with yarns that have been previously bleached.

The common process of bleaching pulicates, into which permanent colours are wove, is, to wash the dressing or starch well out in cold water. To boil them gently in soap, and, after again washing, to immerse them in a moderately strong solution of the oxymuriate of potash; and this process is followed until the white is good; they are then soured in dilute sulphuric acid. If the goods are attended to in a proper manner, the colours, in place of being impaired, will be found greatly improved, and to have acquired a delicacy of tint which no other process can impart to them.

Pulicates, or *ginghams*, which have been wove along with yarn which has been previously bleached, are first freed by washing from the starch or dressing: they are then washed, or slightly boiled with soap. After which, they are completely rinsed in pure spring water, and then soured.

Besides these common processes for bleaching, another has been lately introduced with great success, by Mr John Turnbull of Bonhill-place, in Dunbartonshire, for which a patent was granted him.

This method of bleaching consists of immersing the cotton or linen goods in a pretty strong solution of caustic alkali, and afterwards exposing them to the action of steam in a close vessel, (see Plate LVI. Fig. 3.)

A is the receiver, made of fir-deal boards firmly hooped, into which the cloth is laid loosely on the iron grating C. BB are iron hesps fixed to the side of the receiver, into which another hesp of iron, containing a screw D, is placed. This is moveable, and folds over by a joint, to make fast the cast-iron cover on the mouth of the tub or receiver: the joining of the lid is closely luted by plated rope being nailed to the mouth of the tub. The iron cover is put on its place, or removed at

* By Fixed Colours are here meant, those which resist the action of the alkalis in an eminent degree, with proper treatment. The colours usually denominated fixed, on cotton, are the Turkey or Adrianople red, and its compounds of lilac or purple, by the addition of iron bases; various shades of blue from indigo, together with buff and gold colour, tinged with the oxides of iron.

pleasure, by the hook of a crane being put into the ring E fixed in the centre of the lid. A hole is pierced through the cover, into which a wooden pin F is thrust, the use of which is to know when the steam is of sufficient strength.

The cotton or linen goods having been previously cleaned by steeping and washing, are, after being well drained, steeped in a solution of caustic alkali of the specific gravity of 1.020. After the superfluous alkaline ley has been drained from them, they are arranged on the grating C in the receiver. The cover is then placed on the vessel, and firmly screwed down; and the steam is admitted by turning the stopcock H, of the pipe G, which communicates with a steam boiler of the common construction.

When the steam is admitted, the action of the alkali is increased by the heat, so as completely to dissolve the colouring matter of the cloth. The steaming is continued for some hours, after which the cloth is removed to the wash stocks, or dash wheel, in order to be cleansed: they are again immersed in the solution of alkali, and steamed in the receiver until they are sufficiently white; after which they are soured and washed as in common bleaching. This process of whitening cotton or linen cloth, may also be forwarded by the assistance of the oxymuriatic acid at proper intervals.

By this method of bleaching, a considerable saving of alkali is gained, as the whole is completely saturated with the colouring matter of the cloth. Nine, or at most ten steeps in the alkali, with alternate exposure to the action of the steam bath, being sufficient to bleach linen cloth effectually: Five steeps, with exposure to the steam is sufficient for cotton cloth.

Having thus given a succinct account of the various operations of bleaching, we shall close this article, by making such observations as seem naturally to arise from the subject.

The first inquiry which presents itself is, What are the substances with which linen and cotton cloth is coloured? This is shown by Mr Kirwan in his excellent memoir on this subject, contained in the *Irish Transactions* for 1789.

He precipitated, by means of muriatic acid, the colouring matter from an alkaline ley, saturated with the extract from linen yarn, and found it to possess the following properties. When allowed to dry on a filter, it assumed a dark green colour, and felt clammy like moist clay.

"I took," says he, "a small portion of it, and added to it 60 times its weight of boiling water; but not a particle of it was dissolved. The remainder I dried on a sand heat; it then assumed a shining black colour; became more brittle; but internally remained of a greenish yellow, and weighed an ounce and a half.

By treating eight quarts more of the saturated ley in the same manner, I obtained a further quantity of the greenish deposit, on which I made the following experiments.

1. Having digested a portion of it in rectified spirits of wine, it communicated to it a reddish hue, and was in a great measure dissolved; but, by the addition of distilled water, the solution became milky, and a white deposit was gradually formed: the black matter dissolved in the same manner.

2. Neither the green nor the black matter was soluble in spirit of turpentine or linseed oil, by a continued long digestion.

3. The black matter being placed on a red-hot iron, burned with a yellow flame and black smoke, leaving a coaly residuum.

4. The green matter being put into the vitriolic, muriatic, and nitrous acids, communicated a brownish tinge to the two former, and a greenish to the latter; but did not seem at all diminished.

Hence it appears, that the matter extracted from linen yarn by alkalies, is a peculiar sort of resin, different from pure resins only by its insolubility in essential oils, and in this respect resembling lac. I now proceeded to examine the powers of the different alkalies on this substance. Eight grains of it being digested in a solution of crystallized mineral alkali, saturated in the temperature of 62°, instantly communicated to the solution a dark brown colour; two measures (each of which would contain 11 pennyweights of water) did not entirely dissolve this substance. Two measures of the mild vegetable alkali dissolved the whole.

One measure of caustic mineral alkali, whose specific gravity was 1.053, dissolved nearly the whole, leaving only a white residuum.

One measure of caustic vegetable alkali, whose specific gravity was 1.039, dissolved the whole.

One measure of liver of sulphur, whose specific gravity was 1.170, dissolved the whole.

One measure of caustic volatile alkali dissolved also a portion of this matter."

From the foregoing observations of Mr Kirwan, it is evident, that the lac or resinous matter which is extracted by the alkalies from linen yarn, is in proportion to their capacity for acting upon this colouring matter; and that the vegetable alkali, whether in its mild or the caustic state, is the best solvent of this matter.

We here take the opportunity of remarking, that at most bleachfields they are extremely defective in rendering the alkaline leys properly caustic by quicklime. Into a solution of about four hundred weight of potashes, dissolved in about 300 gallons of water, we have frequently seen only 40 or 50 pounds of quicklime used; and so imperfectly was it applied, as only to be agitated by a rake for five or ten minutes in the cold solution. Quicklime having the power of precipitating the uncombined charcoal and other impurities, the operator was satisfied, that he had given to the alkaline ley its full powers; but this is a mistake. When the alkaline ley is rendered completely caustic, nothing more is necessary but to reduce the quantity of the ley used. By this means the linen cloth will not be too severely acted upon. This process is now carried into effect by the more intelligent bleachers; and at least one-third of the alkali they formerly used is thus saved.

In order to render the alkali sufficiently caustic, the following process may be followed:—To two parts of potash, dissolved in hot water, add one part of fresh slaked lime, finely pulverised. After the lime is added, make the mixture boil; taking care, that it is agitated by an iron rake, to keep it from subsiding and fixing on the bottom of the boiler. After it boils, the agitation will be sufficient to keep the lime in suspension; the ebullition may be continued for two hours, and the lime allowed to subside: the clear liquor may then be run off for use, and the precipitated lime well washed with water, until it loses the alkaline taste. The washings may be kept for making fresh alkaline solutions.

On examining the quicklime which has been used, it will now be found in the state of a carbonate; having, by

its superior affinity for carbonic acid, deprived the potash of this principle, which will consequently be found nearly in the caustic state.

From the experiments of Mr Kirwan, as narrated above, it will be seen, that the power of caustic potash, in dissolving the colouring and resinous matter contained in linen yarn, is at least double the power which it possesses when in the mild or carbonated state. This agrees also with the experience of every well-informed bleacher. Hence at least one-half of the alkali will be sufficient when used in the caustic state, when put in opposition to the quantity which will be required when in the mild state.

As having the alkaline ley nearly of the same specific gravity is of considerable importance to the bleacher, the hydrometer is generally used for ascertaining its strength. Formerly this useful instrument was constructed on no fixed principle, so that when one of them was broken, another could not be procured made to the same scale. This difficulty is now overcome, and the instrument may be had from Mr William Tweedale, of Glasgow, with invariably the same scale. The principle on which he constructs these hydrometers, is, that the scale commences at 1, and every degree indicates .005 of specific gravity. Hence, supposing the alkaline ley to indicate 20 degrees on the scale of the hydrometer, its specific gravity would be $1 + 20 \times .005 = 1.100$, the specific gravity of water being unity. A complete series of these, from No. 1 to 6, indicate the specific gravity of fluids from distilled water as 0, to sulphuric acid 2., the heaviest liquid known. These instruments are now used in most parts of the united kingdom.

From the increase and variable price of potash, and the dependance of Great Britain on foreign nations for this necessary article, it is of importance, that the expediture of it be as much reduced as possible. Accordingly, various attempts have been made to recover the alkali from the strongest waste ley which had been used in the boiling of linen cloth. But the methods which have been followed for this purpose, have, in general, been given up, on account of the great expediture of fuel necessary for evaporating the ley to a proper consistence for procuring the alkali. We shall, therefore, take no notice of the methods which have been unsuccessful; but mention one, which to us appears practicable, and which those who are interested may use with safety. It is scarcely necessary to observe, that the alkaline ley must be supposed to be of such value, as to render the recovery of the potash an object to the bleacher.

At some extensive chemical manufactories, where it is necessary to evaporate very large quantities of liquid to a given strength, at a small expense, in place of evaporating these solutions in iron or leaden boilers, it is found more economical to construct what are called stone boilers for this purpose, Plate LVI. Fig. 1. No. 1, 2. These are nothing more than large oblong chambers, the side walls of which are about two feet high, built into the ground to prevent them from giving way. The outside of the wall is well rammed with tempered clay puddle, to prevent leakage. An arch of brick is then thrown over between the walls, which is covered with mortar to retain the heat. Proper openings are, at the same time, left to examine the state of the liquid: these are covered with a plate of iron. At one end of the chamber, a furnace of a sufficient capacity is built, having a breastwork interposed between it and the li-

quid, over which the flame plays. At the other end of the chamber, a vent of sufficient height is built to carry off the smoke. The fire being lighted, the flame plays along the surface of the liquid, which by this means is evaporated. Some of these stone boilers are so capacious as to contain 10,000 gallons.

In evaporating waste ley for the recovery of the alkali, all that is necessary, after it has been evaporated to the consistence of tar, is, to carry it to a reverberatory furnace, of a proper construction, where, the mass being dried, it takes fire, and burns with a vivid flame. So soon as the heat is sufficiently strong, the alkali melts, and forms a liquid mass, which is run out of the furnace, by a tap-hole at the side of the furnace, into an old boiler which has been previously heated, to prevent the melted mass from sparking up, and burning the workman employed.

On examining the alkali thus procured, it will be found in a state of greater purity than when first used; because, in the incineration, every particle of the resinous and colouring matter is completely consumed, and the carbonaceous matter which it had extracted out of the cloth, reduces any sulphate of potash, which the purest imported alkali always contains, to the state of a carbonate. Hence, when the recovered alkali is dissolved and rendered caustic by quicklime, its effects in bleaching will be found equal, if not superior, to the first sort of potashes.

Another method by which potash, when used in boiling cotton goods, may be freed from a large proportion of the impurity which it contains, is, by the application of quicklime to the waste ley in the liquid state.

It, to a solution of potash, saturated with the coloured extract from cotton cloth, a proper quantity of quicklime be added, and the mixture be well agitated, a decomposition takes place, and the colouring matter is precipitated.

The extract from linen cloth, containing a greater proportion of resinous matter, is not so easily decomposed; yet, if a small proportion of fresh precipitated earth of alum be added to it along with the lime, and the mixture be well agitated, a decomposition is effected.

The impure alkaline solution is rendered caustic, and becomes transparent, although it does not entirely separate from the lac or resinous principle which it had extracted from the linen cloth. In both cases, it separates best from the extractive matter when the solution is cold; and the lower the temperature so much the better.

On account of the comparatively high price of soda, it has hitherto been very little used in bleaching. From the experiments of Mr Kirwan, already mentioned, it will be seen, that the power of soda, as a detergent, is little inferior to potash. A large quantity of barilla, an impure mineral alkali, is imported into the British islands; a considerable proportion of which was, until very lately, used by the bleachers in Ireland, who, from habit, gave it a preference to potashes. So late as the year 1800, the quantity of barilla imported was

	175,629 cwt.
In 1802,	151,796
In 1800, the quantity of potashes imported was	135,400
In 1802, the quantity was only	48,054

Barilla being, as well as potashes, a foreign product, it is a matter of no small importance to know, whether

we can be supplied with alkali, of home manufacture, at a cheap rate. We do not hesitate to say, that, in a very short period, it will be completely in our power.

It is well known to every chemist, that common salt contains the mineral alkali, in the proportion of 53 parts in 100. Could the government of this country be induced to allow the soda manufacturer the free use of this salt, or of sea water, under proper restrictions, we venture to predict, that Great Britain and Ireland would soon render themselves independent of foreign nations for barilla, as well as of a large proportion of the pot and pearl ashes which are used.

The manufacture of soda, of an excellent quality, has already made rapid advances, even under the present restrictions, at London, Newcastle, and Glasgow. At the latter place, and its neighbourhood, no less a quantity than 500 tons is manufactured annually; and large establishments are daily forming for increasing this quantity. It is much to be regretted, that the manufacture of this article, which is of so much consequence to bleaching, dyeing, the manufactures of glass and soap, as well as to many other important branches of commerce, should be shackled by absurd and impolitic restrictions. (w. r.)

BLECHNUM, a genus of plants of the class Cryptogamia, and order Filices. See **BOTANY**. (w)

BLEEDA, a town of Africa, in the kingdom of Algiers, situated at the bottom of a ridge of mountains, which forms part of Mount Atlas. It is encompassed by a mud wall, about a mile in circuit, and has a considerable population, but little trade. See Shaw's *Travels*, p. 36. (j)

BLEEDING. See **SURGERY**.

BLEKINGEN, a mountainous province of Sweden, about 70 miles long and 26 broad, and stretching along the Baltic. It abounds in forests of oak, pine, beech, and birch. The inhabitants are chiefly employed in fishing and hunting; and they carry on a considerable trade in potash, tar, tallow, hides, leather, beams, deal boards, and masts. The shallowness of the soil renders it in a great measure unfit for cultivation. Its principal towns are, Carlscrona the capital, Carlshamn, and Solvitsborg. (j)

BLEMMYES, the name of a people who appear to have inhabited part of Ethiopia; and who, probably from the circumstance of depressing their heads and raising their shoulders, were represented by the ancients as without heads, and as having their eyes and mouths in their breasts. Agathemerus (c. 10. p. 49. *Geogr. Min.* i. ii.) supposes that this people inhabited the part of Ethiopia under the equator, or the vallies of the high chain of Ethiopian mountains. Demetrius of Lampsacus places them in the same region.

This barbarous people appeared in the third century, as the allies of the Egyptians against Dioclesian. "The number of the Blemmyes (says Gibbon), scattered between the island of Meroe and the Red Sea; their disposition was unwarlike, their weapons rude, and unoffensive. Yet in the public disorders, these barbarians, whom antiquity, shocked with the deformity of their figure, had almost excluded from the human species, presumed to rank themselves among the enemies of Rome. Such had been the unworthy allies of the Egyptians; and while the attention of the state was engaged in more serious wars, their vexatious inroads might again harass the repose of the province. With a view of opposing to the Blemmyes a suitable adversary, Dioclesian persuaded the Nobatæ, a people of Nubia, to remove from their ancient habitations in the deserts of Libya, and resign to them an extensive but unprofitable territory above Syene and the cataracts of the Nile; with the stipulation, that they should ever respect and guard the frontier of the empire." See Gibbon's *Hist.* chap. xiii. vol. ii. p. 114; *Strabo*, lib. xvii. p. 1, 172;

Pomponius Mela, lib. i. c. 4.; *Univers. Hist.* vol. xv. p. 475 (F), 491, 497; xvi. 132; xviii. 258. (j)

BLÉNHEIM, a village of Germany, in the circle of Suabia, about 25 miles to the north-west of Augsburg, has been rendered memorable in history, in consequence of the decisive defeat which the French and Bavarians sustained in its neighbourhood from the British and their allies, on the 13th day of August 1704. The two contending armies were composed of the best and bravest troops in the service of their respective sovereigns, and were conducted by the most distinguished generals of the age. The French and Bavarians, amounting to 80,000, were commanded by marshal Tallard and the elector of Bavaria; and the confederates, nearly equal in number, were led on by prince Eugene and the duke of Marlborough. The French army was posted, in a very advantageous manner, upon the eminence of Höchstet; their right being covered by the Danube and the village of Blenheim, their left by the village of Lubzengen and the wood of Schellenberg, and their front by a large valley, which extended nearly two leagues in length, and which was intersected by several rivulets, hemmed in at some places by banks extremely steep, and at others flowing freely over a marshy plain. As this position would soon, by daily fortifications, have been rendered completely impregnable; and, as the enemy would thus have been able to lay waste the neighbouring circle of Franconia, as well as to prevent the confederates from procuring the necessary supplies of forage and provisions, as it appeared from an intercepted letter of marshal Villeroy, that he was advancing to act in concert with the elector of Bavaria, to ravage the country of Wirtemberg, and to obstruct the communication of the allied army with the Rhine; and as the troops of the confederates were in the highest spirits, in consequence of the victory which they had recently gained at Schellenberg, and of their having been joined by a reinforcement under prince Eugene;—by these reasons the duke of Marlborough was induced to run some hazard, in order to bring the enemy to a general engagement, with the utmost possible expedition; and he adapted his plan of attack, with wonderful skill, to meet the dispositions of the hostile army.

The French and Bavarians were formed into two distinct bodies. At the head of the plain, half a mile from the marshy ground, through which the confederates had to pass, 48 squadrons and 10 battalions were drawn up, under the command of marshal Tallard. Marshal de Marsin, a general of great capacity and experience, with the rest of the French, and the elector of Bavaria.

with his own troops, were stationed upon the left, nearer to the woods, and close upon one of the rivulets which flowed through the valley. In the village of Blenheim, which stood in the front of the right wing, and where it was expected that the allies would direct their principal effort, 28 battalions and 12 squadrons were posted for the defence of the place, and for the purpose of attacking the confederates in the rear, should their left attempt to advance against Tallard. To be ready to join these troops, if necessary, or to act as a corps de reserve as exigencies might require, eight more battalions were ordered to the village of Oberklaw; and a few others, at a little distance from these, were stationed near to two mills, between Oberklaw and Blenheim.

On the right of the confederate army, prince Eugene, at the head of the Imperialists, advanced against the Bavarians, and the forces under Marsin; while the duke of Marlborough, with the British and Dutch troops on the left, directed his attack against marshal Tallard. The duke, being aware of the French general's design to entice him across the plain, and to receive him in front, while the troops in Blenheim should fall upon his rear, ordered a part of his division to make an attack upon that village. This detachment, which consisted chiefly of British troops, under major-general Wilkes, began the engagement at 10 o'clock, by making a most gallant assault upon the village of Blenheim; and, though they failed in repeated attempts to dislodge the enemy, they succeeded in taking such a position in its front, as effectually blocked up the French troops which were stationed in the place, and which could only have come out in defile, through very narrow passages. The duke of Marlborough having thus secured his rear from molestation, instantly passed the rivulet, preceded by his cavalry; ascended the hill in a firm compacted body, attacked the enemy's right wing with the utmost vigour, and, in a short time, compelled it to give way. The brave Tallard repeatedly rallied his troops as they retired, commanded ten battalions to fill up the intervals of his cavalry, made a most determined effort to regain his ground; and, by the tremendous fire of his infantry, succeeded, for a moment, in disordering the line of the confederates, and obliging them to recoil about 60 paces. But Marlborough, with the utmost promptitude, ordered three battalions of the troops of Zell to sustain his horse, renewed the charge with redoubled ardour, completely routed the cavalry of the French, and entirely cut to pieces the 10 battalions of infantry, who had been sent to their support, but who were now abandoned by their retreat. Again did Tallard succeed in collecting his broken cavalry behind a few tents; and resolved to make the attempt to draw off the troops that were posted in the village of Blenheim. With this view he dispatched an aid-de-camp to marshal Marsin on the left, directing him, with the troops at Oberklaw, to face the confederates without delay, in order to favour the retreat of the forces in Blenheim. Informed by that commander, that, instead of being able to spare assistance, he could with difficulty maintain his own ground; Tallard was no longer able to sustain the pressing assaults of the victorious squadrons of Marlborough. His cavalry were totally dispersed; his soldiers thrown into the utmost confusion and consternation; and the miserable fugitives driven into the Danube with dreadful carnage. Tallard himself, endeavouring to the last to rally his disordered squadrons, was surrounded at the village of Sonderen,

and made prisoner, together with many officers of distinction in his army.

While these occurrences were passing on the left of the confederate army, the prince of Holsteinbeck, in the centre, at the head of 10 battalions, passed the rivulet, with undaunted resolution, to attack marshal Marsin at Oberklaw; but, before he could form his men on the other side, he was overpowered by numbers, mortally wounded, and taken prisoner. His division, however, supported by some Danish and Hanoverian cavalry, renewed the charge; but were repulsed a second time; and it was only by the arrival of the duke of Marlborough in person, with some fresh squadrons from the body of reserve, that the enemy were compelled to retire. Prince Eugene on the right, having surmounted a multitude of difficulties, sustained a most obstinate opposition, and having seen his cavalry three times repulsed, had at length begun to force the enemy from their ground. The duke of Marlborough, having completed the defeat of the enemy's right wing, had made a disposition to send him reinforcements; but, before these could arrive, the prince had driven his opponents from Oberklaw and Lutzingen, and pursued them as far as Morsdingen and Teissenhoven. The confederates being now masters of the field of battle, surrounded the village of Blenheim, in which so large a proportion of the French army had been posted at the beginning of the engagement; and as these troops were thus cut off from all communication with the rest of their army, as well as unable to force their way through the ranks of the allies, they were under the necessity of capitulating, and surrendered themselves prisoners of war.

The success of the attack has been represented as owing in a great measure to the errors committed by the French commander, in weakening his centre by the detachment of so many troops to the village of Blenheim; in failing to advance against the right wing of the confederates, while making its way through the marshy plain; and in neglecting to drive back the attack upon Blenheim, before the duke of Marlborough had time to form the great body of his troops after passing the valley in his front. The detention of so many of his forces in the village, which at once weakened his front and gave his opponents the superiority in point of numbers; and the distance between his wings, which were still farther separated by the confederates pressing upon their inner flanks, and forcing them to give way in opposite directions, must indeed have contributed in no small degree to the success of the allied army. But the highest praise must, nevertheless, be considered as due to the duke of Marlborough; who concerted the previous arrangements with so much discernment; who took advantage of the mistakes of his antagonists; who rode through the hottest of the fire with the greatest intrepidity; and who issued his orders as occurrences required, with the utmost composure and presence of mind.

'Twas then great Marlbro's mighty soul was prov'd,
That, in the shock of charging hosts unmov'd,
Amidst confusion, horror, and despair,
Examined all the dreadful scenes of war:
In peaceful thought, the field of death survey'd;
To fainting squadrons sent the timely aid;
Inspired repuls'd battalions to engage;
And taught the doubtful battle where to rage.

ADDISON'S *Campaign*.

The loss sustained in this battle by the vanquished, was immense. "By several letters intercepted, (says the duke of Marlborough, writing to the duke of Shrewsbury,) going from the enemy's camp at Dettingen to Paris, dated the 19th instant, they own, that this battle has cost them upwards of 40,000 men, killed, prisoners, and by the desertion since, upon their hasty march, or rather flight, towards the Rhine." Ten thousand French and Bavarians were left dead on the field; the greater part of 30 squadrons of horse perished in the Danube; thirteen thousand were made prisoners; 100 pieces of cannon, 24 mortars, 129 colours, 171 standards, 5600 tents, 300 laden mules, 15 barrels and eight casks of silver, &c. were taken by the victors. On their side 5000 men were killed, and 7000 wounded. The victory was not only complete in itself, but also most important in its consequences. Augsburg was quickly abandoned by the French; the garrison of Ingoldstadt surrendered; and the fortress of Ulm, where the elector of Bavaria had retreated with the wreck of his army, was taken after a short siege. The house of Austria was saved from impending ruin, and the face of affairs in the empire entirely changed.

The following account of this memorable engagement, from the pen of prince Eugene himself, may probably prove gratifying to our readers; and we have, therefore, kept it distinct from the above statement, which has been taken from the most approved historians. "With patience, and without fighting, Tallard and Marsin might have forced me to have abandoned Bavaria; for I had no other place than Nordlingen for the establishment of my magazines. But those gentlemen were impatient, and the elector was enraged at the pillage which I had allowed Marlborough to commit; who,

by that means, was entirely with me. We loved and esteemed each other. He was a great statesman and general. They had 80,000, as well as ourselves. But why did they separate the French from the Bavarians? Why did they encamp so far from the rivulet, which would have impeded our attack? Why did they throw 27 battalions and 12 squadrons into Blenheim? Why did they disperse so many other troops in the neighbouring villages? Marlborough was more fortunate than myself in the passage of the rivulet, and in his fine attack. A little steepness of the bank made me half an hour later. My infantry behaved well: my cavalry very ill. I had a horse killed under me. Marlborough was checked for a moment; but not repulsed. I succeeded in rallying some regiments, which had at first been shy of attacking. I led them back four times to the charge. Marlborough, with his infantry and artillery, and sometimes with his cavalry, got rid of that of the enemy, and went to take Blenheim. We were all driven back for a moment by the gendarmerie; but we ended by pushing them into the Danube. I had the greatest obligations to Marlborough for his alterations in the dispositions according to circumstances. A Bavarian dragoon took aim at me; one of my Danes luckily prevented him. We lost 9000 men; but 12,000 French killed, and 20,800 prisoners, prevented them, this time, from singing the usual *Te Deum* for their defeats; which they make it a point never to acknowledge." *Memoires du Prince Eugene*. BLIGHT. See *AGRICULTURE Index*.

BLIND.

BLIND, an epithet applied to a living creature entirely deprived of the sense of sight. It belongs to medicine to point out the method of curing or alleviating this malady, in cases where it admits of cure or palliation. What we propose in this article, is, to examine the mental, rather than the bodily state of those individuals of the human species, who have been destitute of eyesight from earliest infancy; to estimate the privations under which they labour, and the expedients by which these may be most successfully compensated; to inquire into their capacity of enjoyment, and of mental improvement; and the proper means of rendering them comfortable in themselves, and useful members of society.

It was put as a question, by Mr Molineux to Mr Locke, whether a person, blind from his birth, would, upon being suddenly restored to sight, be able to distinguish, by his eyes alone, a globe from a cube, the difference of which he was previously aware of by feeling? Both these gentlemen were of opinion, that the distinction could not be made by such a person by the sight till first assisted by the touch; and their conclusion seemed amply confirmed by the experience of several persons, who, having been afflicted with cataracts from their earliest years, and afterwards receiving their sight by the operation of couching, appeared at first unable to distinguish any one thing from another, however different in shape and magnitude. A very remarkable case of this

kind has been detailed by Mr Cheselden, the celebrated anatomist, in No. 402. of the *Philosophical Transactions*, of a young gentleman, who was couched by him in the 13th year of his age. As it tends greatly to illustrate our present subject, as well as the general nature of vision, we shall insert its most interesting particulars, in Mr Cheselden's own words.

"Though we say of this gentleman, that he was blind, as we do of all people who have ripe cataracts, yet they are never so blind from that cause, but that they can discern day from night; and, for the most part, in a strong light, distinguish black, white, and scarlet: but they cannot perceive the shape of any thing. For the light by which these perceptions are made, being let in obliquely through the aqueous humour, or the anterior surface of the crystalline, (by which the rays cannot be brought to a focus upon the retina,) they can discern in no other manner, than a sound eye can through a glass of broken jelly, where a great variety of surfaces so differently refract the light, that the several distinct pencils of rays cannot be collected by the eye into their proper foci; wherefore, the shape of an object in such a case, cannot be at all discerned, though the colour may: And thus it was with this young gentleman, who, though he knew these colours asunder in a good light, yet, when he saw them after he was couched, the faint ideas he had of them before, were not sufficient for him to know them by afterwards; and, therefore, he did not think them

the same which he had before known by those names. Now scarlet he thought the most beautiful of all colours, and of others the most gay were the most pleasing; whereas the first time he saw black it gave him great uncasiness, yet after a little time he was reconciled to it; yet some months after, seeing, by accident, a negro woman, he was struck with great horror at the sight.

"When he first saw, he was so far from making any judgment about distances, that he thought all objects whatever touched his eyes, (as he expressed it,) as what he felt did his skin; and thought no objects so agreeable as those which were smooth and regular, though he could form no judgment of their shape, or guess what it was in any object that was pleasing to him. He knew not the shape of any thing; nor any one thing from another, however different in shape or magnitude; but, upon being told what things were, whose form he before knew from feeling, he would carefully observe, that he might know them again; but having too many objects to learn at once, he forgot many of them, and (as he said) at first he learned to know, and again forgot a thousand things in a day. One particular only, though it may appear trifling, I will relate. Having often forgot which was the cat and which the dog, he was ashamed to ask; but catching the cat, (which he knew by feeling,) he was observed to look at her steadfastly, and then, setting her down, said, *So, juss, I shall know you another time.*

"He was very much surprised, that those things which he had liked best did not appear most agreeable to his eyes; expecting those persons would appear most beautiful that he loved most, and such things to be most agreeable to his sight that were so to his taste. We thought he soon knew what pictures represented which were showed to him, but we found afterwards we were mistaken; for, about two months after he was couched, he discovered at once they represented solid bodies; when, to that time, he considered them only as party-coloured planes, or surfaces diversified with variety of paint; but, even then, he was no less surprised, expecting the pictures would feel like the things they represented; and was amazed when he found those parts which, by their light and shadow, appeared now round and uneven, felt only flat like the rest; and asked, which was the lying sense, feeling or seeing?

"Being shown his father's picture in a locket at his mother's watch, and told what it was, he acknowledged a likeness, but was vastly surprised; asking, how it could be that a large face could be expressed in so little room, saying, it should have seemed as impossible to him, as to put a bushel of any thing into a pint.

"At first, he could bear but very little light, and the things he saw he thought extremely large; but upon seeing things larger, those first seen he conceived less; never being able to imagine any lines beyond the bounds he saw. The room he was in, he said he knew to be but part of the house, yet he could not conceive that the whole house could look bigger. Before he was couched, he expected little advantage from seeing, worth undergoing an operation for, except reading and writing; for, he said, he thought he could have no more pleasure in walking abroad than he had in the garden, which he could do safely and readily. And even blindness, he observed, had this advantage, that he could go any where in the dark much better than those who can see; and after

he had seen, he did not soon lose this valuable quality, nor desire a light to go about the house in the night. He said, every new object was a new delight; and the pleasure was so great, that he wanted ways to express it. But his gratitude to his operator he could not conceal; never seeing him for some time without tears of joy in his eyes, and other marks of affection; and if he did not happen to come at any time when he was expected, he would be so grieved, that he could not forbear crying at the disappointment.

"A year after his first seeing, being carried upon Epsom Downs, and observing a large prospect, he was exceedingly delighted with it, and called it a new kind of seeing. And, now, being lately couched of his other eye, he says, that objects at first appeared large to this eye, but not so large as they did at first to the other; and looking upon the same object with both eyes, he thought it looked about twice as large as with the first couched eye only, but not double, that we can any way discover."

Mr Cheselden adds, in another paper printed by itself, that he has brought to sight several others, who had no remembrance of ever having seen; and that they all gave the same account of their learning to see, as they called it, with the young gentleman above mentioned, though not in so many particulars; and that they all had this in common, that, having never had occasion to move their eyes, they knew not how to do it, and, at first, could not at all direct them to a particular object; but in time they acquired that faculty, though by slow degrees.

Some later observations, however, of a similar kind, seem rather at variance with Mr Cheselden's conclusions concerning the first notions of vision of those who have been couched for cataracts, after having been deprived of sight from their earliest years; although, perhaps, the difference may be more apparent than real. In the *Philosophical Transactions* for 1801, there is a paper on this subject, by Mr J. Ware, surgeon, who has had great practice in couching for cataracts, and who had, in this manner, restored to sight many young persons, who had no recollection of ever having seen; all of whom, however, he found had a notion of distance, and of the forms of objects, even from the very first moment that they recovered their sight. The case which he particularly describes in this paper, is that of a Master W., whom he restored to sight at seven years of age, after having been deprived of it by cataracts before he was a year old.

"I performed the operation," says Mr Ware, "on the left eye, on the 29th of December last, in the presence of Mr Chamberlayne, F. A. S.; Dr Bradley of Baliol College, Oxford; and Mr Platt, surgeon in London. It is not necessary, in this place, to enter into a description of the operation. It will be sufficient to say, that the child, during its performance, neither uttered an exclamation, nor made the smallest motion either with his head or his hands. The eye was immediately bound up, and no inquiries made on that day with regard to his sight. On the 30th, I found that he had experienced a slight sickness on the preceding evening, but had made no complaint of pain either in his head or eye. On the 31st, as soon as I entered his chamber, the mother, with much joy, informed me, that her child could see. About an hour before my visit he was standing near the fire, with a handkerchief tied loosely over his eyes, when he told her, that under the handkerchief,

which had slipped upward, he could distinguish the table, by the side of which she was sitting. It was about a yard and a half from him; and he observed, that it was covered with a green cloth, (which was really the case,) and that it was a little farther off than he was able to reach. No farther questions were asked him at that time, as his mother was much alarmed lest the use thus made of his eye might have been premature and injurious. Upon examination, I found that it was not more inflamed than the other eye, and the opacity in the pupil did not appear to be much diminished.

“Desirous, however, to ascertain, whether he was able to distinguish objects, I held a letter before him at the distance of about twelve inches, when he told me, after a short hesitation, that it was a piece of paper; that it was square, which he knew by its corners; and that it was longer in one direction than it was in the other. On being desired to point to the corners, he did it with great precision, and readily carried his finger in the line of its longest diameter. I then shewed him a small oblong band-box, covered with red leather; which he said was red, and square, and pointed at once to its four corners. After this, I placed before him an oval silver box, which he said had a shining appearance; and, presently afterwards, that it was round, because it had not corners. The observation, however, which appeared to me most remarkable, was that which related to a white stone mug; which he first called a white bason, but soon after, recollecting himself, said, it was a mug, because it had a handle. These experiments did not give him any pain; and they were made in the presence of his mother, and of Mr Woodford, a clerk to his majesty’s treasury. I held the objects at different distances from his eye, and inquired very particularly if he was sensible of any difference in their situation, which he always said he was, informing me, on every change, whether they were brought nearer to or carried farther from it.

“I again inquired, both of his mother and of himself, whether he had ever, before this time, distinguished, by sight, any sort of object? and I was assured by both, that he never had on any occasion; and that, when he wished to discover colours, which he could only do when they were very strong, he had always been obliged to hold the coloured object close to his eye, and a little on one side, to avoid the projection of the nose. No further experiments were made on that day. On the 1st of January, I found that his eye continued quite free both from pain and inflammation, and that he felt no uneasiness on the approach of light. I shewed him a table knife, which at first he called a spoon, but soon rectified the mistake, giving it the right name, and distinguishing the blade from the handle, by pointing to each as he was desired. He afterwards called a yellow pocket-book by its name, taking notice of the silver-lock on the cover. I held my hand before him, which he knew, but could not at first tell the number of my fingers, nor distinguish any one of them from another. I then held up his own hand, and desired him to remark the difference between his thumb and fingers; after which he readily pointed out the distinctions in mine also. Dark coloured and smooth objects were more agreeable to him than those which were bright and rough. On the 3d of January, he saw, from the drawing-room window, a dancing bear in the street, and distinguished a number of boys that were standing round him, noticing particularly a bundle of clothes which one

of them had on his head. On the same evening, I placed him before a looking-glass, and held up his hand; after a little time he smiled and said, he saw the shadow of his hand, as well as that of his head. He could not then distinguish his features; but, on the following day, his mother having again placed him before the glass, he pointed to his eyes, nose, and mouth, and seemed much gratified with the sight.”

Mr Ware then proceeds to compare the case of Master W. with that of Cheselden’s patient, and to deduce some general conclusions, which are altogether at variance with those of that celebrated anatomist. He finds that Master W., instead of at first forming no judgment of distance, and thinking all objects touched his eyes, was able to distinguish, at the first moment of his seeing, a table a yard and a half from him; and to prove that he had some accuracy in his idea of distance, by saying, that it was a little farther off than his hand could reach. Instead, also, of being unable to “know the figure of any thing, or any one thing from another, however different in shape and magnitude,” Master W. knew and described a letter, not only as white, but also as square, because it had corners; and an oval silver box, not only as shining, but also as round, because it had not corners. These observations, he says, so contrary to the account we have received of Mr Cheselden’s patient, would have surprised him much more than they did, had he not previously, in some similar instances, had reason to suspect, that children, from whom cataracts had been extracted, had a notion of distance the first moment they were enabled to see. “In the instance particularly of a young gentleman from Ireland,” he subjoins, “fourteen years old, from each of whose eyes I extracted a cataract, in the year 1794, in the presence of Dr Hamilton, physician to the London hospital, and who, before the operation, assured me, as did his friends, that he never had seen the figure of any object, Dr Hamilton and myself were much astonished by the facility with which, on the first experiment, he took hold of my hand at different distances, mentioning whether it was brought nearer to, or carried further from him, and conveying his hand to mine in a circular direction, that we might be the better satisfied of the accuracy with which he did it.”—“In this case, however, and in others of a like nature, although the patients had certainly been blind from early infancy, I could not satisfy myself, that they had not, before this period, enjoyed a sufficient degree of sight to impress the image of visible objects on their minds, and to give them ideas which could not afterwards be entirely obliterated. In the instance of Master W., however, no suspicion of this kind could occur; since, in addition to the declaration of himself and his mother, it was proved, by the testimony of the surgeon who examined his eyes in the country, that the cataracts were fully formed before he was a year old. And I beg leave to add farther, that on making inquiries of two children, between seven and eight years of age, now under my care, both of whom have been blind from birth, and on whom no operation has yet been performed, I find, that the knowledge they have of colours, limited as it is, is sufficient to enable them to tell whether coloured objects be brought nearer to or carried further from them; for instance, whether they are at the distance of two inches or four inches from their eyes; nor have either of them the slightest suspicion, as is related of Mr Cheselden’s patient, that coloured objects, when held before them, touch their eyes.”

The conclusions of Mr Ware and of Mr Cheselden, although they seem so much at variance with each other, may, in our opinion, be perfectly reconciled, upon the very simple supposition, that the patients, upon whom the observations of each were made, were affected with blindness in different degrees. Mr Ware himself informs us, that all the patients whom he had an opportunity of examining, were able to distinguish colours before they were couched; and to such a degree, as "to enable them to tell, whether coloured objects be brought nearer to or carried further from them." This being the case, it is not at all surprising, that the moment they were restored to sight they should be capable of forming a tolerable estimate of distances, and even of distinguishing forms which were simple and well defined. It does not at all appear, however, that Mr Cheselden's patient had so much use of his eyes before he was couched. He could, indeed, discriminate strong colours, such as black, white, and scarlet; but he was totally unable, as this celebrated anatomist expressly informs us, to distinguish the shape of any thing, and does not appear to have been in the least sensible when an object was brought nearer to or farther from his eyes.

As to the fact of his supposing, when he first saw, that all objects whatever touched his eyes, Mr Cheselden is also express in his testimony; and it is difficult to admit, either that so accurate an observer could have been mistaken, or that the ingenious young gentleman, whose case he describes, could have been himself deceived, or have intended to deceive others on this point. If he had no previous conception of visible distance, it is in perfect conformity to the received philosophy of vision, that he should at first be unable to form any distinct judgment concerning it; for it has been clearly shewn by bishop Berkeley, and those who have followed him in this track of investigation, that our estimate of visible distance is not an original but an acquired faculty. That it is not like the perception of colour, or apparent magnitude and form, at once impressed upon the mind; but presupposes a complex process of mental investigation, in which we compare together a variety of particulars made known by the eye, when we look at the same object at different distances; such as its comparative distinctness or obscurity of outline, the brightness of its colours, its apparent bulk, the peculiar adjustment by which we are conscious that the eye adapts itself to a variation of distance, and the change in the inclination of the axis of the two eyes, which a change of distance requires. On account of the great rapidity with which this mental induction, or comparison of particulars, is made, in consequence of constant habit, those who have long used their eyes are altogether unconscious of its ever having taken place. But it has been proved, in a most satisfactory manner, by Berkeley and his followers, that the estimate of visible distance really depends upon such a mental investigation, or comparison: and if this be the case, it is a necessary consequence, that when a person, who has been all his life totally blind, is first restored to sight, he will, for some time, be utterly unable to judge of distances, and will naturally be inclined to believe, that the things which he sees touch his eyes, just as the things which he feels touch his skin.

We have the satisfaction to find this defence of the accuracy of Cheselden's interesting report concerning his couched patient greatly corroborated by a paper of

Mr Everard Home, published in the *Philosophical Transactions* for 1807, and containing two cases of children born with cataracts, whom he restored to sight by couching. These cases are much more in conformity with the case of Cheselden's patient than those of Mr Ware, and clearly prove, that there is a considerable diversity in the degree of blindness which cataracts produce. In the first case, the sight of the patient, a boy of twelve years of age, was so obscured, that he could discern light only, but neither colours nor forms. He was only imperfectly restored to vision; but, as far as could be ascertained, he had no knowledge of visible forms after the operation, and judged all objects to touch his eyes. The other patient, a boy of seven years of age, could distinguish colours as well as light; and, therefore, had some knowledge of distance. In him the operation was completely successful; and he was so charmed with the new sense of seeing, that he took every opportunity of removing the bandage from his newly couched eye. He could distinguish distance immediately, but had long a very imperfect knowledge of forms. "A pair of scissors," says Mr Home, "was shewn to him, and he said it was a knife. On being told he was wrong, he could not make them out; but the moment he touched them he said they were scissors, and seemed delighted with the discovery. On being shewn a guinea, at the distance of fifteen inches from his eye, he said it was a seven shillings piece; but placing it about five inches from his eye, he knew it to be a guinea; and made the same mistake as often as the experiment was repeated." The account adds, that, four days after the operation, he was allowed to go about; when, on going to the window, he cried, "What is that moving?" Mr Home asked him, what he thought it was? he said, "A dog drawing a wheelbarrow. There is one, two, three dogs drawing another. How very pretty!" These proved to be carts and horses on the road, which he saw from a two pair of stairs window. At first, he called all regular shaped surfaces round; but soon learned to distinguish those that were angular.

To persons who have been totally blind from their infancy, it is altogether impossible to impart any notion or conception of light and colours; the eye being the only avenue by which such a conception can reach the mind. This notion, however, seems to be the only one, of all that immense stock of ideas which we derive from sight, that is completely beyond the reach of a blind man's capacity. Of forms, the touch communicates the most accurate information; and distance must be previously ascertained by touch, before it is made known by the eye. Even motion, the perception of which might seem peculiarly to belong to the eye, is only certainly ascertained by the touch; for the eye often considers motion to be real, when it is only apparent. If the ideas of the blind, therefore, be necessarily more limited than those of persons who see, they have the advantage of superior accuracy and precision so far as they extend.

It is not, however, without much cultivation and care, that the blind can be enabled to make those acquisitions, by which they may possess a rational source of enjoyment within themselves, and become useful and important members of society. In that state of mental darkness to which they are naturally exposed by the deprivation of so important a sense, they are objects of the liveliest compassion; and call, from their more fortunate brethren, for all the tenderness and sympathy which enlightened humanity can impart. The language which

Milton has put into the mouth of Samson Agonistes is scarcely too strong for their unfortunate condition, and was, no doubt, dictated by his own painful feelings :

“ O loss of sight, of thee I most complain !
Blind amongst enemies ! O worse than chains,
Dungeon, or beggary, decrepid age !
Light, the prime work of God, to me's extinct ;
And all her various objects of delight
Annul'd, which might in part my grief have eas'd,
Inferior to the vilest now become
Of man or worm.
O dark, dark, dark, amid the blaze of noon
Irrecoverably dark ; total eclipse,
Without all hope of day !”

The appeal which the same poet makes, in his own person, to the sympathy of his readers, in the sublime address to light, in his *Paradise Lost*, is, perhaps, still more pathetic and affecting :

—“ Thus, with the year,
Seasons return ; but not to me returns
Day, or the sweet approach of ev'n or morn,
Or sight of vernal bloom, or summer's rose,
Or flocks, or herds, or human face divine ;
But cloud instead, and ever during dark
Surrounds me. From the cheerful ways of men
Cut off ; and, for the book of knowledge fair,
Presented with a universal blank
Of nature's works, to me expung'd and ras'd,
And wisdom at one entrance quite shut out.”

The following striking picture of the condition of the blind, is delineated by one who had the misfortune to be completely deprived of his eye-sight at the early age of five months,—the well-known and much esteemed Dr T. Blacklock of Edinburgh.

“ There is not perhaps any sense or faculty of the corporeal frame, which affords so many resources of utility and entertainment, as the power of vision ; nor is there any loss or privation which can be productive of disadvantages or calamities so multiform, so various, and so bitter, as the want of sight. By no avenue of corporeal perception is knowledge in her full extent, and in all her forms, so accessible to the rational and enquiring soul, as by the glorious and delightful medium of light. For this not only reveals external things in all their beauties, in all their changes, and in all their varieties ; but gives body, form, and colour, to intellectual ideas and abstract essences ; so that the whole material and intelligent creation lie in open prospect ; and the majestic frame of nature in its whole extent is, if we may speak so, perceived at a single glance. To the blind, on the contrary, the visible universe is totally annihilated ; he is perfectly conscious of no space but that on which he stands, or to which his extremities can reach. Sound, indeed, gives him some ideas of distant objects ; but those ideas are extremely obscure and indistinct. They are obscure, because they consist alone of the objects whose oscillations vibrate in his ear ; and do not necessarily suppose any other bodies with which the intermediate space may be occupied, except that which gives the sound alone ; they are indistinct, because sounds themselves are frequently ambiguous, and do not uniformly and exclusively indicate their real causes. And though by them the idea of distance in general, or even of some particular distances, may be obtained ; yet they never fill the mind with those vast and exalting ideas of extension, which are inspired by ocular perception. For though a clap of

thunder, or an explosion of ordnance, may be distinctly heard after they have traversed an immense region of space ; yet, when the distance is uncommonly great, it ceases to be indicated by sound ; and, therefore, the ideas, acquired by auricular experiment, of extension and interval, are extremely confused and inadequate. The living and comprehensive eye darts its instantaneous view over expansive valleys, lofty mountains, protracted rivers, illimitable oceans. It measures, in an indivisible point of time, the mighty space from earth to heaven ; or from one star to another. By the assistance of telescopes, its horizon is almost indefinitely extended ; its objects prodigiously multiplied ; and the sphere of its observation nobly enlarged. By these means, the imagination, inured to vast impressions of distance, can not only recal them in their greatest extent, with as much rapidity as they were at first imbibed ; but can multiply them, and add one to another, till all particular boundaries and distances be lost in immensity.

“ Thus nature, by profusely irradiating the face of things, and clothing objects in a robe of diversified splendour, not only invites the understanding to expatiate on a theatre so extensive, so diversified, and so attractive ; but entertains and inflames the imagination with every possible exhibition of the sublime or beautiful. The man of light and colours beholds the objects of his attention and curiosity from afar. Taught by experience, he measures their relative distances ; distinguishes their qualities ; determines their situations, positions, and attitudes ; presages what these tokens may import ; selects his favourites ; traverses, in security, the space which divides them from him ; stops at the point where they are placed ; and either obtains them with ease, or immediately perceives the means by which the obstacles that intercept his passage to them may be surmounted. The blind not only may be, but really are, during a considerable period, apprehensive of danger, in every motion towards any place from whence their contracted power of perception can give them no intelligence. All the various modes of delicate proportion ; all the beautiful varieties of light and colours, whether exhibited in the works of nature or art, are to them irretrievably lost. Dependent for every thing but mere subsistence, on the good offices of others ; obnoxious to injury from every point, which they are neither capacitated to perceive nor qualified to resist ; they are, during the present state of being, rather to be considered as prisoners at large, than citizens of nature. The sedentary life, to which by privation of sight they are destined, relaxes their frame, and subjects them to all the disagreeable sensations which arise from dejection of spirits. Hence the most feeble exertions create lassitude and uneasiness. Hence the native tone of the nervous system, which alone is compatible with health and pleasure, destroyed by inactivity, exasperates and embitters every disagreeable impression. Natural evils, however, are always supportable ; they not only arise from blind and undesigning causes, but are either mild in their attacks, or short in their duration ; it is the miseries which are inflicted by conscious and reflecting agents alone, that can deserve the name of evils. These excoriate the soul with ineffable poignancy, as expressive of indifference or malignity in those by whom such bitter potions are cruelly administered. The negligence or wantonness, therefore, with which the blind are too frequently treated, is an enormity which God alone has justice to feel, or power to punish.”
